This question is not yet settled, but it is particularly interesting in view of the close similarity between postural contraction in skeletal muscle and contraction in the smooth unstriated muscle of the hollow viscera and blood vessels. Indeed, Sherrington maintains that postural activity is the mechanism whereby these hollow viscera (stomach, bladder, etc.) and blood vessels normally adapt themselves to variations in the volume of their contents.

In the skeletal system postural activity occurs only in the antigravity muscles—that is, those which constantly resist and counteract the influence of gravity. This does not mean that no other muscles under any circumstances are capable of acting posturally, but that the normal postural or standing reflex involves contraction of the antigravity muscles only, their antagonists being inhibited.

Sherrington pointed out that the failure of many of the earlier experimenters to demonstrate tonus in skeletal muscle was due to their failure to appreciate this fact. Many of the observations were made on the gastrocnemius of the frog, which is an extensor muscle. But the habitual posture of the frog is squatting, not standing, and in this attitude the hind limbs are folded in nearly full flexion. Accordingly, reflex postural activity is found in the flexor muscles of the hind limbs of the frog, and not in the extensors. In Broudegeest's classical experiment demonstrating reflex tonus in the hind limbs of the frog it was the flexor muscles which exhibited the tonus. On the other hand, in the cat, dog, and monkey (and man), it is the extensors which exhibit the tonus or postural activity.

Postural activity in man is essentially a continuous act of extension—extension of the head and neck, the spine, the hips, and the knees—with adduction and inversion of the feet.

The chief characteristics of postural activity as summarized by Sherrington are: (1) the low degree of tension it usually develops; (2) the long periods for which it can be maintained without fatigue; (3) the difficulty of obtaining by artificial—for example, electrical—stimulation reflex contraction at all closely resembling the postural contraction produced by natural stimuli; (4) the relative ease with which reflex inhibition interrupts the postural contraction; and (5) and (6) the "lengthening" and "shortening" reactions obtainable from muscles exhibiting postural contraction.

The tension developed is usually quite mild, but it may be considerable. Usually it is just enough to maintain ordinary postures, and when greater tension than that is required it is obtained by the same kind of contraction as that employed for movements. But this latter kind of contraction cannot be long maintained owing to fatigue.

A remarkable feature of postural activity is its insusceptibility to fatigue. It is well known that phasic or voluntary muscular contraction cannot be maintained for long owing to fatigue. But postural activity can be maintained for long periods—hours or even days—without appreciable signs of fatigue. It has been shown that the energy-cost of a posturally acting muscle is extraordinarily low as compared with voluntary contraction. Indeed, the contrast is so striking as to suggest that these two forms of muscular activity are fundamentally different.

But perhaps the most characteristic feature of postural activity is what Sherrington⁶ has called the "lengthening" and the "shortening" reactions. By this is meant the property which a postural muscle has of adapting itself to different lengths without change of tension. The lengthening and shortening reactions are best seen in cases of decerebrate rigidity, in which postural activity is free from the control of the higher centres. For example, if the extended knee be passively flexed, the limb remains fixed in the position to which it was moved. By this movement the quadriceps muscle is, of course, lengthened. But there is no increase of tension on the muscle. For, if the tension is measured by the weight which the muscle will just counteract, it is found that the weight is exactly the same whether the muscle is in the longer or the shorter state. In other words, the quadriceps adapts itself to and maintains the increased length with exactly the same tension that it possessed before it was lengthened. Similarly, when the flexed knee is extended the quadriceps adapts itself to the shorter length without change of tension. And in whatever way changes of posture are brought about—whether passively or by reflex or by voluntary muscular actions—these lengthening and shortening reactions are appended to the phasic contractions, so that different postures are maintained with the minimum expenditure of energy.

The afferent impulses which give rise to the postural reflex originate in the posturally acting muscles themselves—that is, it is a proprioceptive reflex, and the principal nerve centres concerned are situated in the paracerebellar nuclei. The higher parts of the brain, though not essential to the crude postural reflex, yet normally

exert a reinforcing and modifying influence upon it. In this way posture is influenced by the labyrinth, the cerebellum and the cortex cerebri.

Postural activity is acquired in early life. A newborn child cannot hold up its head, still less can it support its body in the upright position. This is not because the muscles are too weak, but because the nervous mechanism for these actions is not yet developed. In due course, by constantly repeated voluntary effort, the child learns to hold up its head, then to sit, to stand, and finally to walk. The upright attitude thus acquired laboriously by voluntary effort, then becomes habitual and subconscious, and is maintained by reflex tonic muscular activity (postural activity).

When the child begins to stand, the feet are flattened and everted by the body weight; this, again, is not because the muscles are weak, but because postural activity is not yet fully developed. When the child learns to walk, postural activity becomes established, and the feet are adducted and inverted—that is, the tendency to passive abduction and eversion is from that time onwards constantly resisted by reflex tonic muscular activity (postural activity).

Postural activity, then, being the normal mechanism by which the upright position of the body (including the normal attitude of the feet) is maintained, it is to postural activity and its modifications that we should first turn for an explanation when we meet with abnormal departures from the upright position.

SCOLIOSIS.

One of the commonest "static" deformities is scoliosis or lateral curvature of the spine, and gravity is, no doubt, an important factor in its development. The influence of gravity on an initial curve of the spine is to tend to increase it and to bring about those rotatory changes in the vertebrae which are so characteristic a feature of the established deformity.

But gravity by itself is responsible for scoliosis to a limited extent only. In its purest form gravity scoliosis is seen in those cases which arise directly as the result of some occupation, such as carrying heavy weights on one shoulder. In such cases a moderate amount of scoliosis may develop very slowly in the course of years. It is a true adaptation deformity. It cannot be corrected, and it shows little tendency to increase spontaneously.

When the bones are softened by disease the force of gravity may produce severe deformity, as is seen in rachitic scoliosis, though it may be noted that in rickets loss of tone is as marked a feature as bone softening. Again, when the spinal muscles are paralysed, gravity produces deformity, but in this case for a long time the structural changes are slight compared with the extent of the curvature. It is true that severe fixed deformity often occurs in paralytic cases, but, if such a case is compared with a case of postural scoliosis of the same degree, it is remarkable how flexible the paralytic deformity remains, and to what an extent it can be corrected, at least for a very considerable time.

The commonest variety of scoliosis—namely, postural scoliosis—differs in origin, course and development from all these other varieties. It is essentially a progressive deformity, and its progress is often rapid and out of all proportion to the mechanical factors involved.

It has been customary to include in the etiology of this deformity all sorts of conditions which may cause more or less constant curves in the spine. Thus, scoliosis has been attributed to faulty attitudes assumed by children at school, to inequality in the length of the lower extremities, to weak muscles, etc. But nearly every child sits with a crooked back when writing at a desk or table, yet few develop scoliosis. Boys sit just as badly as girls—or worse, yet scoliosis is far less common in boys than in girls. Inequality in the length of the lower extremities is much more common without scoliosis than with it. We all know many cases of short leg from one cause or another, in which there is a constant curve in the spine on standing, but they have not developed scoliosis. Some such cases, it is true, develop a certain amount of curvature which hardly alters at all in the course of many years. It is an adaptation deformity and quite different from the ordinary postural scoliosis.

General debility and muscular weakness is so common apart from scoliosis that it cannot alone be considered as a

cause of the deformity. In cases of actual paralysis of the spinal muscles—which may be taken as the extreme of muscular weakness—the deformity is almost entirely mechanical, and it differs in many ways from postural scoliosis. There is no greater mistake than to suppose that scoliosis is a deformity of weedy girls who are not strong enough to hold themselves up. Most of the cases seen in practice are of quite average muscular development.

It has been said that the ultimate cause of scoliosis is "spinal insufficiency"—one of those clever-sounding phrases which seem to mean a great deal, but which really mean nothing at all. Those who use the expression say that spinal insufficiency is a want of proportion between the weight which the spine has to carry and the "resistance" or carrying power of the spine. They do not say what the resistance is, nor in what way it is "insufficient."

Now, we have seen that the upright position of the body is maintained by continuous reflex muscular activity; that this postural activity is of a special kind, capable of being sustained for long periods without fatigue; and that it is controlled by a special nervous mechanism of its own. A faulty posture therefore suggests, in the first place, a faulty nervous mechanism or an abnormal nervous influence brought to bear upon that mechanism.

It has been mentioned that the labyrinth normally influence postural activity. The natural stimulation of the labyrinth arises from their position in space, and it has been shown experimentally by Magnus and de Kleijn² that postural activity is influenced reflexly by the position in which the head is held. When the head is bent forwards postural activity is inhibited, not only in the extensor muscles of the head and neck, but throughout the length of the spine and in the lower extremities. Conversely, when the head is extended, postural activity is increased. In lateral flexion there is a corresponding adjustment of postural activity on the two sides.

These observations forcibly recall certain attitudes frequently associated with deformities, as, for example, the bent head familiar in cases of adenoids, myopia, neurasthenia, paralysis agitans, old age, and other conditions which are often accompanied by kyphosis. When the head is held erect the spine is usually straight and the lumbar lordosis well developed. Lateral flexion of the head may, I think, find a place in the etiology of scoliosis, either as a contributory causative factor or as determining the localization of the principal curvature.

The cerebral cortex exerts a modifying influence on postural activity, either directly or through the medium of the cerebellum. The hypotonia of cerebellar deficiency and the characteristic posture assumed in some cases of cerebellar disease are familiar to neurologists. It is an everyday observation that, other things being equal, the upright figure and the bent figure reflect two very different types of mind. The difference between the attitude of a street loafer and that of a trained soldier is not merely physical—it is far more mental. In the "setting up" of a raw recruit discipline, drilling, and so-called physical exercises, produce a mental change. By their means a habit is formed, at first conscious and with effort, but finally subconscious and ingrained.

These are variations of posture within normal limits. But I would put forward the view that abnormal postures also are primarily nervous or mental in origin—that postural scoliosis, in fact, originates as a functional nervous disorder. Mental fatigue or inertia—in fact, neurasthenia—leads to deficient postural activity, even though the muscles are well developed and voluntary muscular power is unimpaired. When postural activity is deficient the erect posture is imperfectly maintained, and under the influence of gravity the spine or part of it becomes curved. At first the spine can be straightened by voluntary effort, but, as we have seen, this form of activity cannot be sustained on account of fatigue. Postural activity is essential for sustained muscular action.

The dissociation of phasic and tonic or postural muscular activity is seen in an aggravated form in certain nervous diseases, as, for example, in myasthenia gravis. In this condition the patient is able to perform a voluntary movement, but the tonic or postural activity is absent from the affected muscles, so that the attitude assumed by the voluntary contraction cannot be sustained. Thus, the patient can raise the eyelids voluntarily, but cannot keep

them raised. The muscles voluntarily contracted rapidly tire, and the movement can only be repeated after an interval for their recovery. Normally, a postural contraction would be appended to the voluntary contraction, and the patient would be able to keep the eyes open without effort or fatigue.

The same phenomenon can be demonstrated by electrical (faradic) stimulation of the muscles, and gives rise to a characteristic reaction—the myasthenic reaction. If the muscle is stimulated repeatedly at short intervals with the faradic current, it gives at first a brisk response, but the succeeding contractions become weaker and weaker until at last no response is obtained with the strongest current. Or, if the faradic current is applied continuously, the muscle at first gives a brisk contraction which gradually fades away and disappears, although the current is still passing. After a short interval the muscle recovers its excitability, which, however, again disappears on repeated or continuous faradic stimulation. The galvanic reactions of the muscles are not affected.

I have found the myasthenic reaction to be present in cases of postural scoliosis. Naturally, one would not expect it to be so well marked as it is in myasthenia gravis, though in that condition it is, as a matter of fact, variable. But it has been demonstrable in many cases which I have examined for it, and I think it clearly indicates that deficient postural activity, and not muscular weakness, is the immediate underlying cause of postural scoliosis.

The frequent association of scoliosis with neurasthenia, and with a neuropathic family history, was noted twenty years ago by Oppenheim,⁶ and I have frequently noted the same among my own patients. Again and again I have seen scoliosis coming on apparently without cause in girls who were perfectly well developed, who went to good schools, and who lived apparently in the best conditions. Sometimes in such cases one would obtain a history of overwork—particularly, working for an examination. Sometimes a neurotic tendency or peculiar temperament would be noted in the patient herself. But most common of all, I think, is a history of neurosis of some sort or other in the parents or their immediate relatives. I have convinced myself that the mental condition is of the greatest significance in these patients—often far more so than the physical aspect of the deformity.

But while the functional origin of scoliosis may thus be accounted for, the development of the deformity requires further consideration. Gravity, no doubt, plays a part, but, as I have already said, the progress and fixation of postural scoliosis is often rapid and out of all proportion to the mechanical factors involved. The early fixation of a postural curvature is due to contracture of the soft parts in relation to the vertebrae, and I would suggest that this, in the first place, is of the nature of a functional contracture.

Some light may be thrown on the question of functional contracture by considering the occurrence of contracture in paralysed muscles and in their non-paralysed antagonists respectively. Structural fixation, as has been said, occurs slowly in paralytic as compared with postural scoliosis, and this is in accord with our experience of paralytic and non-paralytic contractures generally. In a case of drop-foot, when all the muscles of the leg are paralysed, shortening of the calf muscles occurs slowly, and for some time after it has begun it can easily be corrected by simply stretching the contracted muscles. But, in a case of drop-foot in which only the dorsiflexor muscles are paralysed, contracture occurs with great rapidity if the foot is not supported, and it firmly resists correction by mechanical means.

The two processes are quite distinct. Contracture in a paralysed muscle is due to loss of elasticity consequent on fibrosis in the degenerating muscle. In the case of non-paralysed muscle, physiologists are generally agreed that lengthening is as much an active process as shortening or contraction. When a muscle has contracted in response to a nervous impulse it requires another nervous impulse to initiate the process of lengthening. The natural impulse for lengthening a muscle is the direct outcome of the impulse for causing contraction of its antagonist. Therefore a break in the arc of reciprocal innervation has a twofold effect. Not only is the paralysed muscle unable to receive impulses to make it contract, but its non-paralysed antagonist is unable to receive the impulses necessary to make it lengthen. The latter, therefore,

having once shortened, remains shortened, and very soon its power of elongation is permanently lost.

In postural scoliosis we have a condition in which postural activity is deficient. The spine is curved to one side, and the law of reciprocal innervation holds good for the erector spinae muscles on either side of the curvature. In order to straighten the spine, the muscles on the convex side must be made to shorten, while at the same time those on the concave side must be made to lengthen. In early cases this can be done to some extent by voluntary action, but, as we have seen, this is quite different from postural activity. The nervous impulses necessary to bring about postural readjustment are not forthcoming. The muscles on the concave side, therefore, remain shortened, and, just as in the case of the non-paralysed antagonists of paralysed muscles, their power of elongation is soon permanently lost. The analogy holds good except for the fact that in the paralytic case the faulty innervation is due to an organic lesion, whereas in postural scoliosis it is functional—that is to say, the brain is unable to initiate the process of postural readjustment.

I would suggest that progressive functional contracture on the concave side of the curvature is the cause of the rapid fixation which occurs in so many cases of postural scoliosis. One is tempted further to speculate whether the structural changes both in the soft parts and in the bones are in any way connected with the sympathetic innervation of these parts. During recent years we have become so familiar with physical effects of functional nervous disorders—for example, cold and blue limb, congestion, sweating, oedema, atrophy, contracture, peri-articular fibrosis, etc.—effects which are nutritional and therefore under control of the sympathetic, that it is no longer justifiable to assume, as once was done, that because a change is structural, therefore it cannot be functional in origin. I shall, however, return to this question in the second part of this article.

TREATMENT OF SCOLIOSIS.

If the foregoing inferences are correct it is obvious that they must have an important bearing on the treatment of scoliosis. How often does one see scoliosis appreciated and treated almost entirely from behind the patient's back! If you want to know whether a patient has got scoliosis, look at her back. If you want to know why she has got it, and how to treat it, look at her face. The face is said to be the mirror of the mind, and you will find there and in her neurological history information of at least equal importance to any that can be obtained from examination of the back.

The principal cause of deficient postural activity is mental fatigue or inertia. Temperament, environment, occupation, and the general state of health are important factors. The child who sits badly at school and develops scoliosis is the child not with weak muscles, but with the overtaxed brain. It may be remarked that this depends more on the mental capacity of the individual than on the actual amount of work done. A clever child may be tempted to compete with older children, while a dull child may be overworked in merely trying to reach an average or a low standard. In such cases it is useless merely to introduce a course of exercises into the ordinary school routine. Either the routine should be radically altered or the child should be taken away from school.

Patients with scoliosis can be divided roughly into three classes—(1) an active type, apparently active in mind and body, and generally well developed; (2) a listless apathetic type, disinclined for exertion, poorly developed or flabby, and lacking interest in her surroundings; and (3) an obstinate type—lazy, careless of appearances, and difficult to influence. Each of these requires different treatment. The active type requires rest or at least curtailment of excessive activity—usually mental; the apathetic type requires stimulation, persuasion and re-education; the obstinate type requires vigorous stimulation, discipline and work.

It need hardly be said that the patient's general condition should be treated. As in neurasthenia generally, change of environment and occupation is often the ideal, but is not often attainable. Anaemia, constipation, adenoids, etc., should be treated if necessary. Strychnine augments the postural reflex, and is the basis of most "tonics," so it may often be given with benefit.

With regard to so-called physical exercises, postural scoliosis is due, not to muscular weakness, but to deficiency of the habitual subconscious state of reflex activity which normally maintains the upright attitude. The object of treatment, therefore, is not to strengthen or develop particular muscles or groups of muscles, but to redevelop a habit—the postural reflex. This may be done now in the same way as originally in early childhood—namely, by voluntary muscular effort constantly repeated until it becomes involuntary, subconscious and habitual—in other words, by exercises.

Exercises are only one of the means to this end. They should be designed to correct faulty postures as such, and not with the idea of developing particular muscles. Intermittent exercises are of little use in themselves. The patient must be got to strive for a constant effect. Her co-operation is essential, and to this end the personality of her instructor is of far more importance than the particular exercises done.

Restoration of the postural reflex is the basis of all curative treatment of scoliosis. If a curvature is flexible, so that it can be straightened by active or passive movement, it will be kept straight when the postural reflex is re-established, and the patient will be cured.

A curvature that is partly fixed by structural changes can be corrected only so far as it can be made flexible. The flexibility of a structural curve can often be materially increased by active and passive corrective movements, but rarely, if ever, can a structural curve be made completely flexible and therefore curable by these means. A moderate amount of fixed residual curvature may be held in check indefinitely, if the postural reflex is re-established. Such a curve, however, tends slowly to increase mechanically under the influence of gravity, just as an occupational or adaptation curvature does, and many such cases eventually show a poor return for the time, labour, and money that has been expended on their active treatment. Therefore, if a curvature is not held in check by a reasonable amount of active treatment, it should be given mechanical support.

With regard to forcible correction and the application of plaster jackets in scoliosis, it is known that, apart from its effect on the distortion of the ribs, this method, like others, depends for its success upon flexibility of the spine. Most orthopaedic surgeons will agree with the finding of the Scoliosis Committee of the American Orthopaedic Association (1916) that no case of fixed scoliosis has yet been shown to have been corrected in the anatomical sense by any method. At best, forcible correction is but a preliminary measure, and if it is not followed by restoration of the postural reflex or by efficient mechanical support, it is both useless and harmful.

The day has passed when it was customary to hang a so-called spinal support on every crooked back. Nearly everyone now treats scoliosis by exercises, and I think that exercises are indicated in the majority of cases. But I would plead for discrimination in their use, as in that of any other therapeutic measure. Some people have made almost a fetish of exercises. One sees cases so treated, literally for years, without any appreciable benefit, and a spinal support is often ordered only as a last resort. Some cases are quite unsuitable for treatment by exercises from the beginning. Exercises in many cases are given without appreciation of their real purpose. They are only one of the means to an end—namely, restoration of the postural reflex, and to attain this end it is the patient, and not merely her spinal column, that requires treatment.

THE Department of Social Hygiene in the League of Red Cross Societies, whose headquarters are at Geneva, will in future be known as the Department for Combating Venereal Diseases. Mr. Walter Clarke has been appointed Chief of this Department and Lieut.-Colonel Ritchie, Assistant Chief. The League has published in English, French, German, Italian, and Spanish two pamphlets concerning the fight against venereal diseases, entitled respectively "The venereal diseases survey" and "Venereal diseases—a challenge to the Red Cross."

Oliber Sharpey Lectures

ON
THE NATURE OF FLUTTER AND
FIBRILLATION OF THE
AURICLE.

BY

THOMAS LEWIS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN OF THE STAFF OF THE MEDICAL RESEARCH COUNCIL;
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON; HONORARY
CONSULTING PHYSICIAN TO THE MINISTRY OF PENSIONS.

LECTURE II.—AURICULAR FIBRILLATION.

In the first of these lectures I have endeavoured to put before you the chief conclusions which we are able to form respecting that rather rare condition auricular flutter, and have stated that flutter as it occurs in man is due to a single wave circulating continuously. In this lecture I propose to deal with the much commoner and therefore more important disorder, auricular fibrillation. Now these two conditions are very closely related, as has been recognized for some years; they are known to be related, not only because of several resemblances, but because the one not infrequently passes into the other. Thus flutter of the auricle, as I pointed out some years ago, may usually be converted into fibrillation by the administration of heavy doses of digitalis, a conversion which is made use of in the treatment of flutter. We shall see presently how the two states are related, and that circus movement underlies both. To explain the interrelation it is necessary for me to expand what I have already touched upon—namely, certain reactions of the auricular muscle to increased rate of beating. We must study in more detail the change which occurs in the length of the refractory period and in the rate at which the waves travel as the rate of beating rises.

INFLUENCE OF HEART RATE ON THE REFRACTORY
PHASE, ETC.

The changes are somewhat complex, and may be illustrated most clearly by means of the accompanying diagram (Fig. I). To the left of the diagram is a double-headed arrow, which represents the length of the auricular cycle when the heart is beating at a normal rate. This cycle is divisible into two parts, as indicated by the two double-headed arrows which stand just to the right of the first; it is divisible into the refractory period, during which the auricular muscle is in the excited or contracted state, and into the responsive period, during which the muscle is inactive or resting. I represent the refractory period in black and the responsive period in white, and the remainder of the diagram shows, on the basis of direct observation, how these two periods are proportioned to each other as the heart rate is raised. As the heart rate rises by equal increments—say from 100 to 150 to 200 to 250, etc.—so the length of the cycle shortens. If the lengths of the cycles, as these shorten, are charted vertically upon a horizontal base line (as in the figure), their ends join up to form a curve, the steepness of which gradually decreases. The curve of the end of the cycle approaches the base line, at first rapidly, but gradually less rapidly. The two lines will meet at infinity. The end of the refractory period also forms a curve which moves towards the base line (it is represented by the top edge of the black portion of the figure). Briefly, the refractory period of the muscle shortens as does the length of the contraction when the heart rate is raised. But the refractory period does not shorten to the same extent as does the length of the cycle; consequently the responsive period dwindles when the rate is advanced. It dwindles until, eventually and at a very high rate of beating, it disappears altogether. When this happens the muscle will not respond to every impulse reaching it; it breaks into what has been termed 2:1 (or half) response—that is to say, it responds only to alternate impulses entering it. That is but natural, seeing that only alternate impulses will fall during the responsive period of preceding cycles. Now the precise manner in which this alternating response is foreshadowed in the mammalian auricle is

* Delivered before the Royal College of Physicians of London, April 14th, 1921.

peculiar, and considerably important; it is necessary thoroughly to understand it. As the rate of beating rises, and the period of responsiveness shortens, a time comes when the muscle develops what is spoken of as a *partially refractory period*. It is a phase of the cycle, during which the muscle as a whole may or may not respond to stimulation. When this partially refractory phase first develops the cycle seems to be divisible into three parts:

FIG. I.—The main diagram illustrates the relation of the refractory period to the length of the cycles when the auricular rate is raised by equal increments from its normal rate to a high level. The black portion of the diagram represents the absolute refractory period, which shortens as the rate is raised (that is, reading from left to right); a curved line indicates the shortening of the cycle itself. P.R.P. = period of partial refractoriness. ABS. R.P. = period of absolute refractoriness.

wholly responsive; the refractoriness fades away gradually (through the partially refractory period) and responsiveness gradually develops. The state of refractoriness is found to be denser as it is traced backwards through the cycle until at last it becomes absolute. The development of the partially refractory phase, which is a phenomenon of high rates of beating, expedites the closure of the gap between the end of the absolute refractory period and the end of the cycle. The precise instant at which the state of partial refractoriness ends is not measurable, but it is certain that, as the rate of beating advances, it soon bridges the gap completely. When this stage is reached the cycle is divisible into two—namely, a phase of absolute refractoriness and a phase of partial refractoriness; there is no true or wholly responsive phase. This state of the muscle is represented in a small diagram above the main figure.

The meaning of the change which I have described is not obscure; it is this: when the rate is sufficiently raised, the muscle fibres do not all contract during each cycle, some contract in alternate cycles only, and the critical rate at which regular response fails is not the same for all the muscle fibres; some fail to respond earlier than do others. During the phase of absolute refractoriness all the fibres are refractory to stimulation, during the remainder of the cycle the fibres one after another recover their excitability, the muscle as a whole becomes more and more responsive therefore, but up to the very end of the cycle some fibres still remain refractory.

I have dealt with this question of partial refractoriness at some length because it is essential that it be comprehended fully and clearly. It is a phenomenon which has fundamental influences upon the action of the auricle beating at very advanced rates. What I especially desire to emphasize is that, at these advanced rates of beating, each excitation wave entering the muscle finds that muscle imperfectly recovered from the passage of its predecessor.

Let us apply the small diagram in the upper part of Fig. I to our picture of a circulating wave. In the diagram of the ring experiment shown in the last lecture I represented the circulating wave in its most simple form. The relations there shown between the advancing crest of the wave and its wake of retreat represent what is occasionally found in actual experiment. More usually, however, the relation in flutter is a little more complex. The gap between the crest and wake does not consist of wholly responsive but of partially refractory muscle (see Fig. II).

The on moving crest encounters many fibres which are responsive; it finds some which are still refractory. These refractory fibres form minute barriers to its progress; it winds its way from side to side, passing only where it finds channels open and ready to receive it. It is as though a second prairie fire followed a first, but followed it at a time when the vegetation formerly burnt had not fully returned to its old condition; there would be places where the cinders of the first fire still blackened the earth, and the second flame in passing would creep around the edge of these before it could go forward. These barriers, by deflecting it, render the onrushing wave sinuous in its course, and delay its progress from point to point.

I said in my first lecture that in flutter the rate at which the wave is transmitted is not usually normal, but that it is slower than normal. We have proof that this delay is not due to change in the rate of fibre conduction, but to small barriers of unrecovered (or refractory) fibres. This observation is one of no little consequence, since it much simplifies our conception of those factors which are responsible for the maintenance

II.

FIG. II.—A schematic representation of the excitation wave as it circulates in flutter. The blackened portions of the ring represent those portions of the muscle which are refractory at a given instant. The crest of the wave travels constantly through muscle in a partially refractory state. The border of the advancing wave is finely serrated.

III.

FIG. III.—A similar representation of the excitation wave as it circulates in fibrillation. The advancing border and retreating wake are deeply creased, and these creanations overlap. The wave is constantly advancing through small and irregular channels of responsive tissue as these open up to receive it.

of circulating waves. These factors are three—namely, the length of the muscle path, the rate of propagation from point to point, and the duration of the effective refractory period. We now see that the second factor is controlled by the third. In large measure the length of the path is also controlled by the refractory phase; for, where several channels are open to the crest of the circulating wave it will take the shortest, and that is the path along which it most closely follows its own wake.

In studies of flutter, and in those of fibrillation, refractory period becomes of prime importance. Its length, and especially the length and character of its partial phase, are responsible not only for the maintenance of circulating waves, but, as we shall see, for the particular form of disordered movement which the auricle assumes.

THE PRODUCTION OF EXPERIMENTAL FIBRILLATION.

It has been stated previously that a frequent first step comes when we produce, by experimenting upon animals, a condition identical with that seen in our patients. In so far as fibrillation of the auricle is concerned that step was taken eleven years ago. At that time a condition termed fibrillation of the auricles was well known to experimenters, and a common form of disordered heart action was recognized in patients; but neither the experimental nor the clinical condition had been examined sufficiently closely to make it clear that the two states are one and the same. This identity was proved when the electrocardiograms of the experimental and clinical conditions were submitted to close comparison by Rothberger and Winterberg and myself in 1909, and when a little later I sought and obtained the opportunity of exposing to view the heart of a horse suffering from the same malady as do our patients.

Since the time of these demonstrations the term fibrillation of the auricle has come to be used universally in describing this particular disorder of the human heart. In Fig. IV I show again electrocardiograms of the experimental and clinical conditions. Treated pictorially the curves of auricular fibrillations are, within certain limits, variable; but exactly comparable variations are to be seen in man and animal. The variability of the picture is in large part governed by the action of the ventricles. As you are aware, the rate of the ventricular action is not always the same, neither is the degree of its irregularity in different samples of fibrillation. It is not difficult to choose from a collection of clinical curves on the one hand and experimental curves on the other hand, examples in which the resemblance is so close as to be convincing. With the details of the curves I need not now detain you, but would remind you of their most constant features. The ventricular representatives (R and T) are frequent and irregularly placed; the auricular representatives comprise a series of oscillations, of irregular form and somewhat irregular incidence and amplitude. The auricular representatives in flutter are united end to end; the action is quite regular and continuous, and its mean rate is approximately 300 per minute. The auricular representatives in

fibrillation are not very dissimilar to these; they are also joined end to end; and the action is again continuous. The auricular action in flutter and fibrillation differs, however, in important respects; thus, in fibrillation it is 50 per cent. faster, the oscillations, having a mean rate of about 450 per minute; another difference is that in fibrillation the cycles are not accurately repeated; sometimes over short stretches of curve there may be at least a suggestion of repetition (as in the last record of Fig. IV), but close measurement will show that it is not precise; moreover, it is not long maintained. Change is the rule.

FIG. IV.—Four electrocardiograms (lead II) illustrating fibrillation of the auricles in man and the dog. The first and third curves are from dogs, and have been taken from recent experiments in which fibrillation of the auricles has been analysed. These two curves should be compared with the second and fourth respectively; these last are examples of clinical fibrillation. R and T are ventricular deflections; *ff* are the oscillations arising from the fibrillating auricles.

THE NATURE OF FIBRILLATION AND ITS RELATION TO FLUTTER.

I have pointed out that the first step in this inquiry was taken eleven years ago, when it was ascertained that the clinical disorder is identical with one which can be produced experimentally; but it is to be understood that we then obtained no close insight into fibrillation *qua* fibrillation. We had obtained knowledge of a disorder of the human heart, and, more important, the means of further investigating it, it is in

respect of these further investigations that I shall now speak. The method of research has been very similar to that employed in the case of flutter. We produce fibrillation of the auricles in an animal by suitable stimulation, and proceed to examine the paths taken by the excitation waves through the muscle while this fibrillation continues. It would be impossible for me to place before you in this lecture the details of this analysis; I can only attempt to acquaint you with the chief conclusions at which we arrive after fully considering

the evidence derived from all sources. The main conclusion is that fibrillation, like flutter, is maintained by a circulating wave. As in flutter, the central circulating wave is a single wave, but the circuit is completed in a shorter time; the auricular cycles, therefore, follow each other more quickly. To what is this quicker movement due ultimately? It is almost certainly due to the path of the circus movement being somewhat shorter than is the case in flutter. Why should the path be shorter? Probably

FIG. V.—A diagram illustrating the successive paths followed by the excitation wave in flutter. The path is finely sinuous, but is in general accurately repeated from cycle to cycle.

FIG. VI.—A similar diagram of the successive paths taken in fibrillation. The path is coarsely sinuous and ever varying, though it continues to progress in a clockwise fashion around a central area.

because in auricles predisposed to fibrillation the effective refractory period is shorter than in those predisposed to flutter. The crest of the circulating wave in both conditions tends to follow close upon its own wake. The refractory muscle forms a ring broken by a small gap; this broken ring, as a whole, revolves. Now the length of the path in this ring at any given instant is obviously controlled by the duration of the refractory period. A decrease in the refractory period shortens the length of the tissue involved in this

state at any given moment; consequently, if the gap remains unaltered, the diameter of the ring must shorten. If a snake glides along the path taken by its own tail, the size of the circle which it inscribes will be controlled by the length of the snake.

We believe that in fibrillation the circuit is smaller in diameter than in flutter. We cannot yet describe with confidence the precise paths which are followed; but there is some direct evidence to suggest that the mouth of the superior cava is one of the circuits which the central wave favours. Where precisely the circuit is situated is of little moment. To recognize that a single circuit exists should suffice.

The difference between fibrillation and flutter is in part one of rate; but that is not the sole difference or even the most important difference. It has been shown to be the rule that in flutter the crest of the circulating wave is constantly passing through tissue in a partially refractory state. The wave as it progresses strikes upon small barriers which render its course finely sinuous. In fibrillation this interference is much exaggerated; the barriers are larger and the crest travels along paths coarsely sinuous. Seemingly, the crest has not a straight or simply curved border of advance; it is deeply and irregularly crenated. Its wake is similarly crenated and the crenations of the one and the other overlap and intertwine; this relation is shown diagrammatically in Fig. III. The crest of advance moves through muscle apparently in a denser state of partial refractoriness than is the case in flutter.

Picture the path travelled by the wave after it has circulated several times in flutter (Fig. V). There is the track of the central re-entering wave; the path taken is finely sinuous, but apart from these very minor variations it is constant. As this mother wave circulates in the main channel it throws off centrifugal waves at each revolution, and these proceed into outlying areas of the muscle, such as the appendices and the sleeves of muscle on the cavæ; along these outlying channels the path is also finely sinuous, but in general constant. The whole muscle of the auricle is involved in each cycle. With each revolution the events are repeated; the waves are signalled with almost perfect regularity in every part of the musculature; at each revolution a wave passes to the region of the A-V node, the responses of the ventricle are, therefore, of an orderly character.

Picture similarly the path which the wave has followed after it has circulated several times in fibrillation (Fig. VI). Everywhere the track is coarsely sinuous. There are the central tracks, spread over a wider band of tissue than in flutter, because the path varies. Speaking very broadly, the same central path is trodden over and over again, but in detail there is no constancy. The wave may, and apparently does, encircle the same central area repeatedly if not continuously, but it staggers along its course; it is a road of many and serious obstacles. For that reason it does not return to its starting point after constant intervals of time; for that reason and because of change in the actual path pursued, the oscillations in the electrocardiograms are of irregular incidence and form. The paths through the outlying muscle also vary. Place contacts on any region of the auricular muscle, and the waves are not signalled regularly as in flutter, but irregularly; a few even fail to arrive at their proper destinations. With each irregular revolution, or at least with most, a wave passes to the region of the A-V node.† These waves arrive at the node more frequently than they do in flutter, for the general movement is somewhat faster; but because the path travelled is coarsely sinuous and variable they arrive at the node irregularly. The responses of the ventricle are therefore irregular.

THE ACTUAL CIRCUITS IN FLUTTER AND FIBRILLATION.

A single circulating wave is responsible both for flutter and for fibrillation of the auricle; in both conditions it follows the re-entrant path repeatedly, though in flutter this repetition is far more exact than it is in fibrillation. We

* Though the band of tissue involved in the average circle is probably of lesser diameter, the shorter diameter is not represented in the diagram.

† The waves which reach the A-V node are approximately one-tenth less numerous than those which flow along the central path. In the average they number, therefore, about 400 per minute in human fibrillation.

possess some definite knowledge of the actual paths followed by the wave in the fluttering auricle of the dog. The wave may encircle the mouth of the superior cava and include a variable amount of tissue lying between this vessel and the inferior cava; or it may encircle together the mouths of both superior and inferior venæ cavæ; it is probable, though it is not proven, that circuits are formed in some instances around the auriculo-ventricular orifices.

In man the rates in flutter are from 240 to 350 per minute; in the dog the rates are 345 to 580 per minute. In other words, the rates in the dog are approximately 50 per cent. faster. Difference in the size of the organ in man is sufficient to explain this difference of rate, if we assume the rate of transmission in the human and canine auricles to be equal. We may arrive at a general, if we cannot arrive at a precise, idea of the ring's circumference in the human subject. Thus, if the rate of a human flutter is 240 per minute, the duration of each cycle is 0.25 of a second; if the rate is 350 per minute, the duration of each cycle is 0.17 of a second. Assume that the transmission rate in flutter is 500 millimetres per second, then the length of the path will be 125 millimetres in the one case and 85 millimetres in the other, and the diameters of the corresponding circles will be 4 and 2.7 centimetres respectively. Thus, if our assumed transmission rate is correct, the circular paths in flutter are of diameters somewhat exceeding the diameters of the chief orifices of the auricle. It is these natural orifices to which we look especially in attempting to locate the actual paths of the waves.

In human fibrillation the rate of movement is faster; it lies usually in the neighbourhood of 450 per minute, the cycle having a duration of 0.13 of a second. If we assume the same transmission rate, then the length of the path would be 66 mm., and the diameter of the circle would be a little more than 2 cm. It will be evident that if this estimate is approximately correct, and if we suppose the chief orifices of the auricle to be those encircled by the waves in fibrillation, that in this last condition the encirclement must be a very close one. The factor which remains in doubt is, of course, the rate of transmission.

These remarks, Sir, bring me almost to the end of what I propose to record in the present lectures. I may have been tempted to speak of possible remedies for the state of affairs which I have described, but the subject is still unripe for discussion; perhaps I have said enough in indicating what seems to me one of the chief lines which investigation should take; it is an investigation of the refractory period of heart muscle, a search for remedies which will influence the duration of this refractory state, and which, by prolonging it, will help us to close the gap between the crest and wake of the circulating wave; for this gap is essential to the maintenance of the circulating wave, whether the circulating wave is responsible for flutter or for fibrillation.

Finally, the lecturer proceeded to demonstrate shortly his recent experiments with Dr. Drury and Dr. Hiescu upon the movements of the electrical axis of the auricle in clinical flutter and fibrillation. If suitable planes are chosen it can be shown, in both these conditions, that the electrical axis changes its direction in a definite and striking manner; it revolves through 360° as each auricular cycle is completed. As the electrical axis may be taken as an index of the general direction in which the wave is travelling, these observations demonstrate that in flutter and fibrillation the wave travels in a circular fashion through the auricle. Taken in conjunction with the experimental evidence, they constitute proof of simple circus movements in the human auricle affected by these two disorders.

Note.—Full references to the work on flutter and fibrillation will be found in the original papers published in *Heart*, vols. vii and viii.

On the occasion of the 25th anniversary of the discovery of the Roentgen rays a monument will be inaugurated at Petrograd to Professor Roentgen and a street will be named after him.

The fifth meeting of the German Urological Society will be held at Vienna from September 23rd to October 1st, when the following subjects will be discussed: (1) Pathology and treatment of hydronephrosis, (2) surgical anatomy of the bladder and ureters in relation to extensive resections.

THE ETIOLOGY OF RICKETS:

AN EXPERIMENTAL INVESTIGATION.

BY

D. NOËL PATON, M.D., F.R.S.,

REGIUS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF GLASGOW;

AND

A. WATSON.

(From the Institute of Physiology, University of Glasgow.)

(Abstract.)

SINCE 1907 investigations upon experimental rickets in dogs have been carried on in this laboratory, first by Leonard Findlay,¹ then by Renton and Madge Robertson,² and subsequently by Noël Paton, Findlay, and Watson.³

These last experiments showed that while all the pups of two litters kept in the laboratory upon an abundant supply of whole milk and oatmeal porridge developed rickets, two pups from each of the litters kept in the country on skimmed milk and oatmeal remained free of the disease.

The present series of observations shows that pups kept in the laboratory develop rickets even on an abundant supply of milk fat (as much as 7.5 or even 11 grams per kilo) and oatmeal porridge, but that those on the same amount of separated milk (0.2 to 0.7 gram of milk fat) and porridge develop the disease more rapidly. The energy value of the separated milk diet was necessarily lower than that of the full milk diet (207 to 267 calories as against 270 to 437 calories), and hence it is possible, as is suggested by the observations on infants by Hess and Unger,⁴ that a low energy intake may predispose to the disease, although it is not a causal factor.

To test this the next experiment was arranged so that pups of three litters, which were available at the time, should have the diet increased proportionately to their increase in weight, and that the energy intake should be kept ample throughout the period of growth, but that, while one series of pups should have the energy supplied largely from whole milk—fresh and dried—with bread, another should have it from dried separated milk and bread, another from lard, which the Vitamin Committee⁵ of the Medical Research Council class as a fat free of their anti-rachitic vitamin, and the last series from dried separated milk and bread. Scrupulous care as to cleanliness was observed throughout this experiment.

The result was that all the pups, with one exception, reached fifteen to eighteen weeks free of rickets, although those upon the separated milk and bread diet had only 0.3 to 0.6 gram of milk fat per kilogram per day.

The basis of Mellanby's⁶ experimental work is that separated milk up to 250° to 350 c.cm. and white bread, even with linseed oil, yeast, and orange juice, will not prevent the onset of rickets in pups between six and twelve weeks of age, while whole milk will prevent it, and upon this is based the practical recommendation of the Vitamin Committee,⁵ p. 99, that full cream milk should be used by children for the prevention of the disease.

Butter is placed with cod-liver oil (p. 102) as the substance richest in "fat-soluble A or anti-rachitic factor," but both of the two pups in our series to which butter was administered in large quantities developed rickets, while its administration failed to cure or to prevent the advance of the disease in another.

Our experience indicates that by attention to strict cleanliness it is possible to rear pups free from rickets in a laboratory. It is easy to rear them in the open air, even on a diet poor in milk fat. The work of Morpurgo on white rats, and the study of an epidemic of rickets among foxhounds in Adelaide by Bull,⁷ taken along with our results, point to the probability that a bacterial infection of the same non-specific character as that which the investigations of McCarrison have shown to be the causal factor in goitre, plays an important part in the etiology of the disease.

A point of considerable interest demonstrated in our observations is the more rapid growth of the pups kept in the open air.

CONCLUSIONS.

1. In young dogs, under ordinary laboratory conditions, a liberal allowance of milk fat up to even 14 grams per kilo of body weight neither prevents the onset of rickets nor cures it when it has developed.
2. Pups kept largely in the open air may escape the development of rickets on an intake of less than 1 gram of milk fat per kilo body weight.
3. With scrupulous care as to cleanliness it is possible to rear pups free of rickets in the laboratory on an intake of only about 0.5 gram of milk fat per kilo of body weight, along with bread, provided that the diet affords an adequate supply of energy.
4. The energy value of the diet, however supplied, quite apart from the presence of any hypothetical anti-rachitic factor in milk fat, would seem to play a part in controlling the development of rickets, but that it is only a contributory part is shown by the development of rickets in pups with a high energy intake when they are confined in the laboratory without scrupulous care as to cleanliness.
5. Milk fat may be reduced to about 0.3 gram per kilo of body weight, if its place is taken by an equal amount of lard, without the onset of rickets.
6. The results of these observations do not support the conclusion of the Accessory Food Factors Committee of the Medical Research Council that rickets is a deficiency disease due to lack of an anti-rachitic factor associated with milk fat.

A TUBERCULOSIS IMMUNIZING VACCINE.

BY

NATHAN RAW, C.M.G., M.D., M.R.C.P., M.P.,

PRESIDENT, TUBERCULOSIS SOCIETY OF GREAT BRITAIN.

Or all the serious infections of the human body tuberculosis is the most hopeful, both as regards its prevention and also its cure, provided that treatment can be commenced early enough and continued long enough to give the affected tissues time for repair.

In spite of an enormous amount of research, continued in all parts of the world, we have reluctantly to admit that we have not yet obtained a specific remedy which will effectively destroy tubercle bacilli in the body. We must therefore rely on producing a sufficient immunity in the tissues to resist the attack by virulent tubercle bacilli. This immunity can be obtained:

1. By increasing the natural resistance by means of increased nutrition and sound hygienic conditions.
2. By producing an artificial active immunity in the tissues to the tubercle bacillus itself.

Increased care in infant welfare, better wages to the industrial classes, good nourishing food, a pure milk supply, the prevention of overcrowding, and, above all, good housing conditions and the segregation, of open cases of pulmonary tuberculosis, will obviate to an increasing extent the possibility of direct infection; but all this will take many years to accomplish. In the meantime I feel strongly, from my experience of treating many thousands of cases of tuberculosis in hospital, that we have at our disposal a scientific means by which we can secure some immunity to the bacillus, and certainly of preventing the extension of the disease in the human body when once introduced. Fortunately for civilization, the tubercle bacillus is a parasite and not a saprophyte. It has no existence outside the living body, otherwise the whole community would be endangered.

In the *BRITISH MEDICAL JOURNAL* of 1903 I published a preliminary note, the gist of which was that human and bovine tuberculosis were separate and distinct infections, producing a different set of symptoms in the human body. The lesions caused by the human bacillus (direct infection)

* A detailed account of the experiments is published in the April number of the *British Journal of Experimental Pathology*. The expenses of the investigation were defrayed by the Medical Research Council.

are pulmonary tuberculosis, tuberculous laryngitis, secondary intestinal ulceration, and, in some cases, lupus. The lesions due to the bovine bacillus, and generally caused by infected milk in the early years of life, are tuberculous glands, mesenteric tuberculosis, surgical tuberculosis of bones and joints (frequently), tuberculous meningitis, and some cases of lupus.

I still hold to this classification and differentiation of the effects of the two forms of bacilli, and, in addition, I firmly believe that the one form confers an immunity in the body to the other. In fact, the two varieties of bacilli will not exist together in the body at the same time.

To some extent this is of great importance in treating the disease, as we are only able to produce immunity in animals by using human bacilli of ordinary virulence, or by attenuating the bovine bacillus to such an extent that it is non-pathogenic.

After treating over 2,000 cases of tuberculosis in hospital with Koch's tuberculin, prepared from virulent cultures, I came to the conclusion that, although a certain amount of success was obtained, the results were not on the whole satisfactory. The uncertain action of the tuberculin and the alarming reactions, sometimes produced, were very disconcerting, and there is no doubt that in some cases quiescent tubercle was stirred to acute activity.

For this reason I came to the conclusion that it was essential to use cultures of very low virulence, and to avoid, if possible, general febrile reactions. The only certain way of permanently attenuating virulent cultures of tubercle bacilli is by long-continued and systematic subculturing spread over a number of years. In 1905 Professor Koch gave me in Berlin a pure culture on glycerin agar of human bacilli from the sputum of an advanced case of pulmonary tuberculosis. Professor Calmette supplied me with a pure culture of bovine tuberculosis obtained from the mesenteric glands of a cow, and Professor Bang of Copenhagen gave me a pure culture of avian bacilli from the liver of a chicken.

These cultures have been subcultured on glycerin potato and then transferred to glycerin agar, every month for fourteen years in my laboratory, and the present growths represent the 184th generation. The growths are still profuse and true to type, but they are quite non-tuberculinogenic and completely non-pathogenic to animals. Every year since 1906 I have injected these bacilli into animals with a view to testing their pathogenicity. Until the year 1912, that is, the 94th generation of subcultures, I noticed no change in their virulence. After that time attenuation became marked, and in a series of animal inoculations of these bacilli in 1913 and 1914 they were observed to be avirulent.

The war interfered seriously with my experiments, but I took the cultures to France and continued the work there for four years, inoculating hares, rabbits, and guinea-pigs in 1916 and 1917. The cultures were in all cases non-pathogenic. In 1919 I inoculated more animals at the Lister Institute, and although large doses were given, no infection whatever was conveyed, and the animals remained alive and well for four months.

These experiments, which have occupied me for fourteen years, conclusively prove that virulent tubercle bacilli can be attenuated to such a degree as to be avirulent and non-pathogenic to highly susceptible animals, and in my opinion we have in our hands a remedy against tuberculosis which will be of the greatest value, not only in the cure of the disease, but what is of still greater importance, in its prevention, by protecting the human body against attack.

Natural attenuation, while removing the virulence and toxicity of the organism, enhances the value of the vaccine in the treatment of disease. In the case of small-pox the immunity derived from an inoculation of the virus from the pustules of vaccinia is considerably greater than that which results from an attack of variola, because the defensive elements in the body have not been weakened in overcoming the virulence of the toxin.

Treatment of disease by vaccines prepared from organisms attenuated naturally means that the production of antibodies will take place rapidly without any preliminary shock to the system such as invariably follows the injection of a vaccine prepared from a virulent strain of bacteria. Hitherto it has not been possible to test this in

tuberculosis, owing to the length of time necessary to produce a non-pathogenic strain of the tubercle bacillus.

The results of my work on animals conclusively prove that immunity against infection is produced by the injection of attenuated bacilli, and it is reasonable to suppose that the same thing will hold good in the human. Cattle can be rendered immune to virulent bovine bacilli by previous inoculation with virulent human bacilli; and I am convinced that there is a marked antagonism in the human body between human and bovine infections. It is an indisputable fact that these two organisms cannot flourish in the body at the same time. A child who develops primary abdominal tuberculosis with involvement of the mesenteric glands, or an infection of the neck glands, which are usually caused by the bovine bacillus conveyed in tuberculous milk, is immune to infection by the human bacillus for the remainder of life, and young adults attacked by the human bacillus, producing primary pulmonary tuberculosis, are immune to bovine infections for the rest of life.

The scientific means at our disposal at present for the accurate differentiation of human and bovine infections in the body are not sufficiently accurate to be decisive. There are atypical strains of bacilli which cannot be classed with certainty in either group, and the varying virulence of these bacilli and their effect on susceptible animals is still a matter of some uncertainty in a fair number of cases.

With a view to elucidating this doubtful point as to the real amount of tuberculosis in man caused by these two types of bacilli, and also as to the immunity produced by one infection towards the other—in other words, in order to obtain an answer to the question whether the disease caused by the human bacillus is antagonistic to that caused by the bovine bacillus and vice versa—I instituted clinical observation on a large scale in a Liverpool hospital containing 900 beds, of which I had sole charge for eighteen years. During that time I had the opportunity of treating over 10,400 persons suffering from tuberculosis in all its various forms.

Two hundred beds were devoted to tubercle. Half of these were cases of primary pulmonary tuberculosis; the other half of surgical tuberculosis—glands, bones, joints, and lupus. During a period of thirteen years 4,800 cases of phthisis passed through the human wards and 1,820 cases of surgical tuberculosis passed through the bovine wards—a total of 6,620 patients.

The object of the observation was to see what other lesions, if any, were developed in the patients suffering from pulmonary tuberculosis, and how many of the surgical cases developed lesions in the lungs. I was assisted in this work by many excellent house-physicians and nurses, and the results were very striking and important.

In no case of primary pulmonary tuberculosis did we observe during the course of illness tuberculosis of bones, joints, glands, or skin, nor any instance of meningitis. Several cases developed brain symptoms in the last stages of the disease, but they were due to insanity, toxæmia, or exhaustion, and of the cases with meningeal symptoms, those examined *post mortem* were found to be cases of pneumococcal meningitis.

Amongst the surgical cases of tuberculosis 28 developed lung symptoms, and these were all examined by laboratory methods and animal inoculation; 25 died and were carefully investigated *post mortem*. In all cases the infection of the lung was either by direct extension from cervical glands to the apex of the lung, or from a primary focus in the abdomen extending upwards through the diaphragm to the bronchial glands and lungs.

This large clinical experiment convinced me that the human body is attacked by two quite distinct forms of tuberculosis—the one conveyed from person to person by direct infection and attacking chiefly the lungs, or so-called consumption, and the other conveyed by milk from tuberculous cows, and developed in the first few years of life.

These two diseases are caused by different types of tubercle bacilli which will not live in the body at the same time, and, what is of the highest importance, one disease produces immunity to the other.

I have emphasized this point of antagonism between the two infections to show my reason for always using a vaccine prepared from bovine cultures in the treatment of the human infections and vice versa.

The varying degree of virulence of the attacking organism is of supreme importance. The great majority of cases of tuberculosis are fortunately of low virulence, and, given suitable conditions, are favourable for treatment; but in some cases the virulence is so high as to destroy the person in a few weeks or months, and these are the cases popularly known as galloping consumption.

From my own observation I am inclined to think that in this country the virulence of the tubercle bacillus is less than it was thirty years ago. The number of deaths in England and Wales from tuberculosis in 1920 was 12,000 less than in 1919, a most gratifying record of progress in dealing with this terrible disease, which destroys 60,000 lives each year in England alone.

A large percentage of the population receive at some period of their lives a mild infection of tubercle which, in many cases, produces no definite symptoms. These persons recover, and are to some extent immunized against a further and more severe infection.

If we can induce some immunity by artificial means in children whose parents or relatives are tuberculous, and who by constant association with them are very liable to infection, we will have gone a long way towards stamping out tuberculosis. As Roemer says, "The most important problem in the prophylaxis of consumption is the saving of children in phthisical homes from severe tuberculous infection."

The vaccine which I have had prepared from these attenuated cultures is a bacillary emulsion of the bacilli, and contains all the products of the bacillus. It is non-toxic and avirulent, and produces no reaction even in large doses.

For purposes of immunization in susceptible children six injections are given at weekly intervals, and repeated in three months. The doses recommended are 0.001, 0.002, 0.003, 0.004, 0.005, and 0.006 mg. No symptoms whatever have been observed to follow these injections.

In the treatment of the active disease the doses used are much larger than have been possible hitherto; it is recommended that the treatment should consist of at least twelve injections given in increasing doses at intervals of seven days. The doses commence at 0.001 and increase to a maximum dose of 0.025 mg. The vaccine should be freshly prepared from the cultures, and should not be used after one month.

Our chief object in the treatment of active tuberculosis is to limit the spread of the disease in the organs. If we can locate a recent deposit in the apex of a lung, and can locate a recent extension throughout one or two lobes, the patient will have a good chance of recovery, and I maintain that we can only do this if we can provide his blood with some active immunity with which to resist the infection.

This vaccine, prepared as it is from avirulent cultures, can be used with complete safety in any stage of the disease, and even in advanced cases I have observed great relief from night sweats, toxic symptoms, and erratic temperatures. I have treated 118 cases of tuberculosis with various forms of the products of these attenuated bacilli, but I have decided that the bacillary emulsion is the best preparation.

The results in suitable cases are excellent, but it would require at least two years to gauge accurately the effect of the vaccine for purposes of immunization.

I have succeeded in completely immunizing highly susceptible animals against tuberculosis by the use of attenuated cultures which have required fourteen years' subculturing in the laboratory, and I firmly believe that if all children with a tuberculous history could be safely vaccinated in the manner I have described they would be placed in a better position to resist infection at home.

Prevention is better than cure; and if we are to eradicate consumption, as I firmly believe we will, it can only be by preventing infection of healthy people, and especially children, rather than by devoting all our energies to the cure of those already infected.

The amount of tuberculosis conveyed to infants and young children in milk derived from dairy cows suffering from tubercle is enormous. It is estimated that over one million dairy cows in this country alone are tuberculous, and there seems to be no improvement in this disgraceful state of affairs. The simple process of raising the temperature of the milk to 190° F. makes it perfectly safe,

and does not in the slightest degree impair its nutritive value. Sterilized and proprietary milks are quite safe, and free from tubercle, and should be used in preference to unboiled cow's milk.

THE SURGERY OF THE PERIPHERAL NERVE INJURIES OF WARFARE.

BY

HARRY PLATT, M.S.LOND., F.R.C.S.ENG.,

SURGEON, AND SURGEON-IN-CHARGE OF ORTHOPAEDIC SERVICE, ANCOATS HOSPITAL, MANCHESTER; SURGEON-IN-CHIEF, GRANGETHORPE ORTHOPAEDIC HOSPITAL (MINISTRY OF PENSIONS), MANCHESTER.

ANALYSIS OF A PERSONAL SERIES OF OPERATIONS.

General Survey.

AN analysis of the total operations performed in my services in the period from March, 1915, to December, 1920, is given in Table I. The figures may be taken as representative of an average individual operative experience, and it is therefore safe to refer briefly to certain general information that the statistics themselves afford.

The frequency with which the ulnar nerve called for treatment, the infrequency of operations on the brachial plexus, and the complete absence of any operation on either the musculo cutaneous or circumflex nerves in the upper limb, or the anterior crural nerve in the lower limb, are facts to be noted.

In the various types of operation the phases through which the operator passed are illustrated in the large number of operations of the bridge type, and those in which repair was abandoned.

Analysis of Results.

Of the operations in this series it has been possible to investigate the early and later results over periods extending from six months or more in 248 only.

It must be admitted at the outset that this study includes few if any *bruz* end-results. The most reliable records in our possession are those of the operations performed since 1917, when the advantages of a more efficient segregation of the patients, and the inauguration of the follow-up system were available. But though the conditions were such as in civil surgery might be considered ideal, the greater number of the patients could be kept in hospital for short periods only, and were then distributed in various parts of the country. This difficulty, which has been experienced by all surgeons, explains the comparative paucity of the operation statistics hitherto available.

TABLE I.—Total Operations.

	Suture.	Neurolysis.	Bridge.	Repair Abandoned.	Partial Future.	Exploration: No lesion.	Exploration: Nerve left in situ.	Injection.	Exploration First Stage.	Total.

* Part of a Hunterian Lecture on The Results of Operations on the Repair of Nerve Injuries, delivered before the Royal College of Surgeons of England.

In this post-operative study the presence or absence of signs of recovery have been recorded after personal examinations only. Whilst many patients living at a distance have from time to time replied to inquiries as to their progress, suggestions in their reply indicating recovery or otherwise have always been ignored. It is perhaps unnecessary to lay stress on the fallacies of conclusions drawn from such impersonal investigations; my excuse is that one has occasionally seen in the possession of out-patients forms which were to be filled up recording the impressions of the man himself on the alterations in the sensory and general functional condition of his limb.

The 248 operations from which information as to results have been available include 150 cases of end to end suture, 80 of neurolysis, and 18 of bridge operations.

RESULTS OF END-TO-END SUTURE: 150 OPERATIONS.

In a preliminary report based on a study of 271 suture operations, issued a year ago by my colleague Stopford,¹ the bulk of my own operations up to date were included. The experience of a further period of twelve months has made it possible to collect additional evidence concerning the fate of a considerable number of the patients with whom we have been in touch.

TABLE II.—End to end Sutures. Total, 150.

	Total.	Proximal Muscles only.	Proximal and Distal (incomplete).	Proximal and Distal (total).	Distal alone.	Associated sensory recovery.	Sensory recovery alone.	Number of Recoveries.	Failures.
Musculo spiral . . .	35	10	11	5	—	all	—	25	9
Median									
Upper arm	10	7	3	—	—	in 5	—	10	nil

Plexus	3	2	—	—	—	2	—	2	1

Recovery, 118 = 79 per cent., failure, 32.

The frequency and type of recovery after nerve suture are illustrated by the statistics in the tables. The facts as to the recovery of motor function are arranged under the headings of the proximal and distal muscle groups, a classification which is found to be convenient, particularly for the upper limb. In the whole series there are no examples of absolutely complete and perfect recovery, excepting possibly in 5 of the cases of musculo-spiral and 2 of those of external popliteal suture.

The operations in which the existence of recovery is charted include every variety and type of incomplete restoration of conduction in the sutured nerve. It is not considered a logical procedure to classify such recoveries into further arbitrary special divisions, such as "slight," "marked," and so on, for the simple reason that the periods of post operative observation are not constant for any one group of allied operations. Given long periods of time, many of the imperfect recoveries of to day will progress, or have already progressed, towards the stage of complete recovery. The standard of failure adopted in my analysis is the complete and stationary absence of recovery after a year or more, in some cases confirmed by evidence obtained on re-exploration.

With regard to sensory recovery, in very few cases has there been more than a slight recession of analgesia or an incomplete restoration of protopathic sensibility.

The information and conclusions as to the late results of suture may best be embodied in a consideration of the main factors which have determined, delayed, or entirely prevented success.

1. The Period of Delay between the Original Injury and the Performance of the Operation.

In my own series the influence of the time factor has been definitely proved. As a general rule suture performed within a period of eighteen months show little appreciable differences in the time of the onset of recovery, or the rate and ultimate completeness of the recovery. After a delay of two years recovery is often tardy or incomplete; in some cases it fails completely. This truth has long been established as a fundamental factor in prognosis in the older nerve surgery (Kennedy).

My records confirm what has been pointed out in Stracker's careful analysis of the operations performed in the clinic of Hans Spitzly of Vienna—that the degree of delay within the safe period does not influence the performance of the recovery, and does seem to be of the same type of the regeneration. . . . or, quite apart from other influences, plays an important part. It is assumed that this is dependent on the development of permanent retrogressive changes in the spinal cells, and to a much less degree to peripheral degenerative changes in the muscles. On the other hand, it would appear from the analysis of the operation results in the service of Sir Harold Stiles of Edinburgh that this factor exerted a negligible influence (Forrester Brown).

2. The Recrudescence of Septic Infection in the Limb.

Recrudescence of infection at a period after the suture was seen in a number of cases in my series; where this arose spontaneously it does not appear always to have affected the regenerative process, but it has been my fate to see a definite recession in the regeneration which had already begun, after the exploration of an associated ununited fracture, followed by infection. This unfortunate sequela is one which could have been avoided, and perhaps is hardly to be cited as a fair test of the resistance or lack of resistance to sepsis of the regenerating nerve. In the recovery stage of a number of cases of suture of the sciatic nerve the trophic ulceration seen under the base of the fifth metatarsal, or in the terminal phalanx of the great toe, where definite necrosis has resulted, provides a continued source of infection, which might conceivably be absorbed and travel upwards towards the area of suture. Delay or cessation in recovery has been invariably associated with this complication, and I would suggest that it is in some way connected with the absorption by the regenerating nerve of distal sepsis.

3. Anatomical Situation of the Suture.

The distance of the line of suture from the spinal centres, or conversely from the distal extremity of the limb, is seen to be an important factor in determining the fate of the regenerative process. This is illustrated by a study of the time of onset of the appearance of recovery in the muscles supplied at successive levels, and in a comparison between the results of suture in the proximal and distal parts of the limb respectively. The times of the appearance of recovery in the chief muscle groups have been carefully charted in Stopford's recent contribution, and are seen also in the monograph of Stracker already referred to.

Recovery in the proximal muscles begins at an earlier or later date according to the proximity of the suture to the spinal cord, and occurs in regular descending fashion in accordance with the anatomical origin and distribution of the motor branches. Thus, for example, after suture of the musculo spiral nerve in the upper, middle, and lower third of the arm, return of power is manifest in the supinator longus at about the seventh, sixth, and fourth months respectively. Distal recovery also shows these differences in time relation. In Stracker's figures no recovery was seen before one year after suture in the distal muscles of the musculo spiral, median or ulnar supply, and this irrespective of the level of the suture. On the whole this is borne out by the records of my own operations. Thus the time taken in neurotization of the distal muscles is not entirely dependent on the distance which down-growing axons have to travel. It has been concluded from this that the results of suture are better in the proximal part of the limb than in the distal. Stracker states that, in general, sutures below the origin of the proximal muscle branches give bad results. This would appear to be correct as a broad statement, but on careful

examination requires certain qualifications. If the results of suture of the median and ulnar nerves in the upper arm and forearm are compared as regards distal recovery alone, both motor and sensory function combined, which means that a period of twelve months at least must have elapsed, the quantitative recovery appears to be roughly equal in each group.

4. Influence of Topography.

The inaccuracies of regeneration due to the shunting of motor fibres along sensory channels and vice versa are undoubtedly one of the causes of imperfection in the recoveries, and may be of such a degree as to determine complete failure. It has been impossible in a close perusal of one's operation records to correlate in each case the potential influence of this factor with the type of recovery seen. In the sciatic nerve sutures it has been easy to retain an accurate topography, whilst in the musculo-spiral the comparatively scanty sensory bundles, even when misdirected, have not prevented the transmission of a large proportion of motor fibrils along appropriate channels. The exact rôle of topographical errors, as applied to the individual operations, cannot be settled until it is possible to examine a large number of successful sutures of the median and ulnar nerves after a period of three years or more. In certain situations—for example, in the lower half of the forearm—where suture of either the ulnar or median nerves has been achieved with what might be claimed as faultless topography, little direct proof of its beneficial effect is obtained.

Topographical failure is best illustrated by the suture of a nerve of smaller calibre to a larger trunk, as in the case of suture of the posterior interosseous to the musculo-spiral, and of the anterior tibial and musculo-cutaneous to the external popliteal—operations which account for 8 cases traceable in my series, and in all of which complete failure resulted. The topographical factor in regeneration is, however, usually cited as an illustration of the apparent superiority of the results of suture of the musculo-spiral nerve over those of the median and ulnar nerves, and of the delay or absence of recovery in the distal muscles.

5. The Influence of Perineural Surroundings— The Nerve Bed.

It does not appear from my own observations that the perineural surroundings have influenced the occurrence of recovery after nerve suture in any way, except in a few cases where the nerve trunk has been subjected to the friction of a bony groove, as in the case of the ulnar at the elbow, or has been left in close relation to bare tendons—for example, median suture at the wrist. The deleterious effects of a nerve bed of this type have contributed to the complete failure of one case of ulnar and one of median suture, but such failures are to be regarded as preventable.

6. The Influence of Complications.

(a) *Vascular*.—In a number of upper arm sutures of the median or ulnar nerves or both, where ligation of the brachial artery has been performed in the early days of the injury, there has been little appreciable effect on the rate and degree of recovery. Where contractures and other signs of ischaemia have coexisted and the total mechanical disability is naturally great, the clinical evidences of the recovery of the nerve have often been masked.

(b) *Non-union of Fractures*.—The continued existence of non-union of a fracture without active inflammatory signs in the neighbourhood of the recovering nerve has retarded or prevented recovery in two musculo-spiral sutures in my series; one showed a failure of distal regeneration after four years, and the other a total absence of any sign of recovery. These failures are to be attributed to the effect of tension and friction.

7. The Continuance of Active Interstitial Neuritis in the Proximal Nerve.

This is a potent cause of delay or failure, which theoretically is avoidable by a free resection preparatory to suture. But it is certain that histological evidence of interstitial change may often be present in the proximal part of the nerve trunk when there is little or no macroscopical sign of its existence. Where there has been a long delay owing to the presence of inveterate sepsis in the limb, the interstitial neuritis finds its maximum

development. In my own operations complete failure or imperfections in recovery have been dependent on this factor, and particularly in the sciatic nerve, where the ill effects are manifested during the stage of tardy recovery by the development of the signs of irritation. In three cases, after a period of more than two years, the pain in the internal popliteal distribution is a most serious handicap to the patient and continues to defy every form of treatment. On the other hand, in one of the complete recoveries after musculo-spiral suture definite evidence of interstitial neuritis was seen in the proximal part of the nerve trunk at the time of operation, and, owing to the size of the gap, the suture was performed at a level which was considered far from ideal.

Qualitative Results of Nerve Suture.

It remains now to judge the results of these nerve sutures from a qualitative standpoint. In this estimation it is necessary first of all to eliminate from the total disability of the limb the contribution of the coexisting injuries of other tissues. But function dependent on a restoration of nerve conductivity alone is itself essentially complex. Success depends not merely on the simple restoration of adequate motor and sensory conduction, but on the development of co-ordination in the particular movements in which the efferent and afferent supply of the sutured nerves are concerned.

In the musculo-spiral sutures where full conductivity has been restored, and where recovered muscle groups have achieved considerable power, there has been as yet no perfect individual extension of the fingers, no synergic function in the extensor muscles of the wrist, and there is on the whole an imperfect control over the extensor muscles of the thumb.

In the median nerve poor function has been the rule, chiefly owing to the very limited sensory recovery. The helpless anaesthetic index finger, which is characteristic of most of these cases long after the operation, is a striking illustration of the importance in function of a restoration of the median sensory mechanism.

In the ulnar nerve, where there is often a mobile hand without contractures, the gross function is little diminished even in the presence of a complete syndrome of interruption, and full restoration is of little moment except for the skilled worker. To many of these hands the addition of conductivity in the ulnar nerve has made little or no difference in function.

The full sciatic syndrome in itself does not cause gross loss of function in the lower limb as regards the act of walking. It is difficult to estimate the increased value of the motor recovery, which at the best has been moderate power in the calf and a less complete and powerful action in certain muscles of the extensor group.

RESULTS OF THE OPERATION OF NEUROLYSIS.

Whilst it is possible to study the results of end-to-end sutures in a truly mathematical fashion, a scrutiny of the results of the operation of neurolysis is beset with many difficulties. It will be sufficient to reiterate and amplify from a consideration of the results in 80 cases what is regarded in my opinion as the legitimate scope of this operation.

In the results are seen both recoveries, partial and complete, and complete failures. There have been no rapid recoveries within the period of nerve regeneration, for the type of lesion in which this might have occurred has not been explored. Where recovery has been seen it has been on the conventional lines of the ordinary regeneration as regards time and general progress. A certain number of operations have been premature explorations for lesions of a low grade, in which spontaneous regeneration was at the time proceeding. Where failure of recovery has occurred the intraneural changes have been of such a nature and extent as to inhibit the down growth of regenerating axons, and the extraneural operation has failed to alter the intraneural conditions. Whilst improvement has occurred in the neurological syndrome after the operation of neurolysis in 75 per cent. of cases, it has been impossible to prove that the operation itself alone has determined this.

For these reasons I would urge that the limitations of the operation of neurolysis as a definitive factor in the surgical treatment of the warfare lesions of nerves are to be fully realized.

RESULTS OF OPERATIONS FOR CAUSALGIA.

My series includes 25 operations performed for severe causalgic manifestations, 14 on the median nerve, 10 on the sciatic nerve, and 1 on the internal popliteal nerve.

1. The median operations consisted of (a) resection and suture on eleven occasions (twice on the same nerve); (b) neurolysis on two occasions, and (c) one intraneural injection of quinine and urea. Of the resection and suture operations complete relief of pain followed immediately in nine; the pain was lessened but persisted indefinitely in the two resections performed in the same nerve in one patient. In this case there existed a grave contracture and a useless concealed hand when the man was first seen; ultimately the limb came to amputation. The cause of failure was the persistence of intraneural fibrosis in the nerve trunk, and its upward spread for many inches proximal to the line of suture.

Both neurolysis operations failed to produce relief and early re-exploration was necessary; in each, resection and suture was carried out with complete success.

The one intraneural injection for a mild case of causalgia produced a moderate degree of relief, and the pain showed signs of diminution with ultimate disappearance in a few months.

2. The results of resection and suture of the sciatic nerve were as satisfactory as in the case of the median, judging by the immediate relief afforded, but during the recovery stage, in three cases, the return of severe irritation has been a disappointing experience. The cause of this is also to be attributed to the progressive intraneural fibrosis.

3. The one neurolysis operation performed on the internal popliteal nerve, for what appeared to be a true severe causalgia, was followed by immediate cessation of the pain. In this particular case a strong functional element was present, and it is not certain that true causalgia existed, although the symptoms were mimicked very closely.

In the exploration of a nerve which exhibits a condition of profound irritation, the hyper-excitability of the nerve trunk and the muscles supplied by it, both above and below the lesion, is a striking phenomenon.

The efficacy of the operation of early resection and suture for severe causalgia is beyond criticism. It would appear to be a more exact procedure than the equally or even more destructive method of alcohol injection. It has not been my experience to meet the type of case in which still more drastic procedures have been inevitable, such as section of the posterior roots.

The operation of Leriché, stripping of the periaxial sheath, is founded on an erroneous conception of the anatomical situation of the vasomotor fibres of the limb, and is to be mentioned merely for the sake of completeness.

GENERAL CONCLUSIONS ON THE LATE RESULTS OF NERVE OPERATIONS.

References have been made from time to time to the results quoted in other contributions to the literature of the peripheral nerve surgery of the war. From this literature, already vast, it has been impossible to collect and compare on any recognized standards the total statistics as to the late or end results of the various forms of operations. From a wide study of this literature, and an intensive study of my own material, it is possible merely to enunciate broad generalizations influenced in particular by the consideration of the causes of failure and success.

During the past year it has become increasingly difficult in this country, at any rate, to keep in touch with the patients who have been operated upon, even during the last two years. The chances of acquiring further comprehensive knowledge regarding true end-results would therefore seem to be slender. This is a bitter disappointment after the labours of a number of years. But, for some little time, a small stream of patients with nerve injuries still unoperated on, or showing failure after previous operation, will continue to flow into the surgical centres of the Pensions Ministry. Such patients, on the whole, are now undesirous of submitting to operative procedures. But the surgical lessons gained from the amount of experience behind us are yet to be applied for the benefit of a few. And it is of great economic importance that clear indications as to the advisability at this date of the exploration or re-exploration of the injured nerves should be laid down.

Every lesion will date back at least two years, so that the optimum period for the surgical repair of the nerve is now past. But for perhaps a year longer it will be worth while advising operation in selected cases. Before doing so, the economic value of the restoration of nerve conduction to the future capacity of the limb must be gauged. In many limbs an operation is now a waste of time. From a serious consideration of the problem as it presents itself at the time, it is suggested that the exploration or re-exploration should be considered under the following conditions:

1. In complete lesions of the median or ulnar nerves in the upper arm restoration of function in the proximal muscles is to be expected, even after long periods of delay, but distal recovery may probably not take place. For lesions of these nerves, in which conduction is already present as far as the proximal branches, with the total failure of distal regeneration, exploration is on the whole advisable; but short of resection and suture, which may be unjustifiable, nothing can be done.

2. In complete lesions of the median and ulnar nerves in the forearm the potential restoration of sensation in the median is of such great importance as to warrant making every effort to ensure its occurrence. In lesions of the median in which partial sensory conduction is present, but with complete motor loss, resection and suture at this date should be strongly condemned. For the ulnar, where the intrinsic muscles are alone inactive, resection is always worth while.

3. In all complete sciatic lesions where end-to-end suture can be reasonably expected.

4. In musculo-spiral lesions exploration of the nerve should precede the performance of tendon transplantation.

ALTERNATIVE OPERATIONS.

Although a technical consideration of those alternative operations for the restoration of function where nerve repair has been deliberately abandoned, or has failed to ensure conduction or function, is outside the scope of the present study the question of the appropriate time and indications for their exhibition is one which is intimately concerned with the observations on the failures and successes of the suture operations.

Where the nerve lesion is declared to be irreparable after an exploratory operation, the indication for the performance of an alternative operation is clear. But in the case of imperfect function following the incomplete restoration of conduction the rôle of the alternative operation cannot be so readily defined. Many of the operations performed under the latter heading have been premature, and have been done early in the reconstructive surgery of the war when the normal prolonged stage of recovery of the injured or repaired nerve was not fully realized. The capacity for regeneration and ultimate function of the nerve after repair is apt to be minimized. Every surgeon who has lived close to this problem must have felt at times despondent. The immediate failures, or late failures, are easily explained, and many of the causes can be avoided. It is likely from what we have seen of the behaviour of the regenerating nerve that after long periods of time, in a considerable number of instances there will be well marked recovery of function. It is to be admitted, on the other hand, that to wait for a future recovery of uncertain value is likely to be unsound. Again, the alternative operation itself may in no way jeopardize the recovery of the nerve, and therefore little harm can be done by its early performance. Few of the alternative operations have entered permanently into one's surgical repertoire. In the upper limb these are above all the now classical operation of tendon transplantation for irreparable musculo-spiral injuries, the results of which are extremely gratifying; the simple tendon transplantations for restoration of flexion of the fingers or thumb in median and ulnar injuries; and, in the lower limb, the destructive operation of tenodesis of the ankle as an alternative to the lifelong wearing of apparatus.

Recently a new procedure has been added to the alternative operations which belongs to peripheral nerve surgery itself. This is the implantation of the proximal end of the radial nerve into the median nerve at the wrist—an attempt to restore that lost sensory function in the median area which produces such a grave incapacity. This operation was introduced by Harris of Toronto, and is

supported by the report of one successful case. For the few irreparable lesions of the median nerve in the forearm this operation may be worth a trial.

HERPES AND VARICELLA.

BY

E. H. R. HARRIES, M.D., B.S.LOND., D.P.H.,
 MEDICAL SUPERINTENDENT, BIRMINGHAM CITY
 HOSPITAL, LITTLE BROMWICH,

AND

EVELYN DUNDERDALE, M.B., CH.B. EDIN.,
 ASSISTANT MEDICAL OFFICER, BIRMINGHAM CITY HOSPITAL,
 LITTLE BROMWICH.

THE following account of an outbreak of varicella in a ward, apparently originating in a case of herpes zoster, seems of sufficient interest to record.

W. G., female, aged 8 years, was admitted to a diphtheria ward on November 16th, 1920, suffering from a severe attack of that disease. Unfortunately she developed scarlet fever from another case admitted with diphtheria, who was also incubating scarlet fever. W. G. was transferred to a small ward, X, on the same day. Here were three other children, M. T., A. F., and L. Y. For administrative reasons these four children were moved on January 27th to a large ward, F., containing twenty-five beds and cots.

On February 4th, a week after transfer, W. G. developed what appeared to be a typical herpes zoster over the area supplied by the twelfth dorsal and first lumbar nerves on the left side. The distribution extended completely round the left side of the trunk, within the area indicated—that is to say, from the mid-line in front to the mid-line behind. The lesions were closely set and went through the usual changes of herpes zoster. As the question of the relationship of herpes and varicella was in our minds for investigation when opportunity should arise, a careful examination was made for scattered lesions elsewhere on the body, and none were found. The point that we should like to mention particularly is the fact that the child had absolutely no pain, either before or during the persistence of the lesions. Herpes zoster, of course, is commonly a painful affection. W. G. had no previous history of varicella and presented no scars of a former attack.

On February 17th—that is, thirteen days after—three children in the ward developed varicella; on the following day, the 18th, four more showed the typical lesions, and by February 27th another child had incubated the disease. The position of the children in the ward, their respective ages in years, and date of onset of varicella, were as follows:

South Side of Ward.	North Side of Ward.
No. of Bed.	No. of Bed.
1. Died. S.F. and Diph.	14. X. Aged 5.
2. V.P. Aged 6.	15. X. Aged 3½.
3. V.P. Aged 5½.	16. M. T. V. Aged 4.
4. X. Aged 6.	17. X. Aged 5.
5. W. G. Aged 8. Herpes zoster.	18. X. Aged 4.
February 4th.	19. A. F. V.P. Aged 6.
6. L. Y. X. Aged 7.	20. V. Aged 2½. February 17th.
7. V.P. Aged 9.	21. V. Aged 4. February 17th.
8. V. Aged 7. February 27th.	22. V. Aged 2. February 18th.
9. V.P. Aged 7.	23. V. Aged 5. February 18th.
10. X. Aged 12.	24. V.P. Aged 7.
11. X. Aged 6.	25. X. Aged 8.
12. V. Aged 5. February 18th.	
13. V. Aged 6. February 17th.	

V.P. = Varicella previously. X. = Exposed to infection.
 V. = Exposed to infection and developed typical varicella.
 L. Y., M. T., A. F. = three patients from Ward X.

No case of varicella had occurred in the hospital for some weeks previously, and certainly the case of herpes has not been exposed, as far as is known, to any risk of varicella infection. When W. G. developed herpes she had been in hospital about eleven weeks. There had not been a previous case of herpes zoster in the hospital for some months, and then it occurred in a ward far removed from W. G.'s, and, it should be noted, was not followed by varicella. W. G.'s herpes arose *de novo*. Did she originate the outbreak of varicella, or was there a missed case presenting only one or two lesions, the time relationship being merely a coincidence?

Morphologically, W. G.'s lesions were typical of herpes zoster. She had no previous history of varicella, nor scars of a former attack, neither has she since developed varicella as a result of contact. The complete absence of pain or even of appreciable malaise are noteworthy. The incuba-

tion period of thirteen days is on the short side as compared with previous ward outbreaks of varicella in this hospital in the earlier part of last year. Previous outbreaks have had an incubation period of from seventeen to twenty-one days. The incubation period of varicella is of course very variable, and the present outbreak may be due to another strain of the virus. Varicella in this country is practically never fatal. The experience of one of us (E.H.R.H.) at a military infectious diseases hospital in Mesopotamia was that varicella in Indian troops and followers was very common and frequently severe, death from pulmonary complications being by no means unknown. Careful pathological investigation of such cases might lead to important information upon the etiology of the disease.

CHRONIC SUPPURATIVE OTITIS MEDIA: FOLLOWED BY LEFT TEMPORO-SPHENOIDAL ABSCESS AND MENINGITIS.

BY

F. HOLT DIGGLE, F.R.C.S.,
 SURGEON-IN-CHARGE, AURAL SERVICE, ANCOATS HOSPITAL,
 MANCHESTER.

THE following case deserves recording by reason of (1) the presence of pus cells and bacteria in the cerebro-spinal fluid, and (2) the reaccumulation of pus in the brain after having been once successfully evacuated, with extensive paralysis and ultimate perfect recovery.

L. P., female, aged 23 years, was admitted to hospital on October 27th, 1920, in a drowsy condition, with a temperature of 101.6°, pulse 82, respirations 20.

History.

The history was only obtainable from the patient, as she had no relatives or friends. When roused she stated that she had had ear trouble (doubtful on which side) since Christmas, 1919, the cause unknown. She had severe pain in the left side of the forehead and left temporal region in Whit week 1920, and visited a hospital in the district, obtaining some relief. The headache had been worse for the last three weeks.

Condition on Admission.

She was drowsy, but could be roused to answer questions. She was slightly aphasic, complained of headache on the left side of the head. She had vomited twice since admission.

Nervous System.—(a) Motor: There was slight weakness in the grip of the right hand, no other paresis or paralysis. The sphincters were normal. There was some rigidity of the neck muscles. (b) Sensory: There was nothing abnormal as far as one could ascertain in her drowsy state. (c) Reflexes: There was slight increase of the right knee-jerk. The right superficial abdominal reflex was brisk. No ankle clonus or Babinski reflex was present. (d) Eyes: The pupils were dilated, equal, reacting to light. The discs were not examined. There was no nystagmus, no photophobia. There was marked loss of the naming centre.

Ears.—The right membrane had a small central perforation with a viscid purulent discharge. The left had marked mental stenosis, a large vascular polypus obstructing the already narrow meatus. There was no visible otorrhoea. There was no tenderness or oedema over the mastoid processes, no pain on percussion of the cranium. The tissues of the neck were normal.

Lumbar Puncture.—There was positive pressure and a cloudy cerebro-spinal fluid. (See pathologist's report below.)

Operation (October 27th, 1920).

A radical mastoid operation was performed on the left side. The mastoid antrum was full of pus under great pressure, and very foul. The dura mater of the middle fossa, exposed by disease, was covered with granulations bulging and pulsating, and the middle ear was full of granulations. The lateral sinus and dura mater of the posterior fossa, exposed by chisel, were found to be healthy. The remains of the tegmen tympani with a portion of the squamous portion of the temporal bone were removed, and the left temporal lobe was explored. A large abscess containing very foul pus was evacuated and drained by two rubber tubes side by side (diameter ½ inch). The auricle was stitched forward and a buttress built around the margin of the wound with gauze so as to avoid pressure on the tubes.

Pathologist's Report (Dr. Renshaw).

Cerebro-spinal fluid: Pus cells were present. A large number of Gram-negative diplococci were in the film (? *Diplococcus mucosus*), present in culture, also in agar, in large numbers.

Pus from brain abscess: Staphylococci and streptococci were present in pus in large numbers, and some long thin curved Gram-negative bacilli (anaerobes). Necrotic debris was present, but very few pus cells. Later, *Diplococcus mucosus* was found in a culture of the brain pus.

hours, and

hours

the patient was greatly improved. The wound was very local. Tubes were inserted, followed by a copious discharge of pus. The abscess cavity was gently irrigated, and the tubes replaced.

November 6th, 1920. Mentally the patient was good, taking her food well. Temperature and pulse were normal. The wound was cleaner, and the tubes being naturally expelled, were shortened.

November 11th, 1920. The patient's temperature was 101°, pulse 120, respirations 18. The wound was looking very clean. The patient appeared very well and had no complaint. The tubes had been expelled two days ago. There was an oedematous-looking bulging of the brain, into which sinus forceps were gently inserted, but only a few drops of a clear fluid were evacuated. In the evening the patient suddenly became unconscious and completely paralysed on the right side, with severe headache (band to left side of head), temperature 102°, pulse 125, respirations 18, pupils dilated, the right side of the face immobile, and the face cyanotic. The sinus forceps were inserted into the brain cavity, and at first clotted blood was evacuated, but at a depth of 2 1/2 in. (superior, forward, and slightly towards from the legmen antrici) a copious discharge of pus and gas was evacuated. A tube would not remain in situ, so the oedematous hernia cerebri was excised flush with the tegmen, and the cavity was lightly packed with gauze.

The patient made a slow uninterrupted recovery. The temperature gradually subsided after reaching 101.6° on November 13th, and was normal by November 21st, remaining so. An extensive hernia cerebri, dressed with green protective, drained well and gradually subsided without any lumbar puncture being performed. The paralysis gradually improved. On February 11th, 1921, the patient walked normally, there was no sign of any paresis, the wound was healed, the ear dry, and she was mentally well. On being seen on March 6th, 1921, the patient was very well and mentally sound.

In conclusion, I wish to draw attention to the following: (1) No tenderness, pain, or oedema over the mastoid, by no means uncommon. (2) Exposed dura mater was pulsating well (a pre-operative lumbar puncture performed). (3) Lumbar puncture was never employed therapeutically throughout the course of the disease.

As an explanation of the sudden onset of coma on November 11th, 1920, I would suggest that the septic focus still present in the brain had ulcerated through a blood vessel, producing a sudden haemorrhage with compression and hemiplegia (clot was first evacuated from the second brain abscess cavity). Naturally my first impression was that the abscess had ruptured into the lateral cerebral ventricle, a supposition which is, I think, untenable having regard to the subsequent progress of the case.

MEDICAL, SURGICAL, OBSTETRICAL.

ENCEPHALITIS LETHARGICA TREATED WITH INFLUENZA BACILLUS ANTIGEN.

IN the BRITISH MEDICAL JOURNAL of March 27th, 1920, one of us (W. M. C.) related the histories of four cases of lethargy treated successfully with pure influenza antigen (vaccine). The paper has apparently received little attention, since recent literature reveals no ideas as to the nature of the infection, much less does it reveal any successful line of treatment. We think it, therefore, desirable to relate the following case, the treatment of which with pure influenza antigen was just as dramatically successful as that of No. III of the other cases previously recorded.

The patient, a girl aged 5 years, living in the South of Ireland, was taken ill on February 18th, 1921, with shivering, drowsiness and headache most intense behind her eyes. She was seen (by D. C.) on February 21st, when her temperature was 102.6° F., the pulse 120. She was asleep, and could only be roused with difficulty; when the eyes were open the conjunctivae were seen to be injected—the typical pink eye of influenza. She was very emaciated, necessitating enemata, but she had not incontinence of urine. There was a watery discharge from the nose. She had muscle twitchings—very marked in the eyelids. When roused she answered questions slowly but intelligently, but was profoundly asleep again within a few minutes. Her temperature fell to 99° F. and her pulse to 75 by February 24th, but the lethargy seemed to increase, the patient only being awake when aroused

been given a few more increasing doses of antigen.

The rapid relief after the first dose, just as
diagnostically as the local and general
second dose, makes it certain to our minds that the
influenza bacillus was the causative microbe. Unfortunately, owing to the distance from a laboratory, no satisfactory bacteriological examination of the nasal discharge could be made, and it was not attempted.

The antigen used was made from a normal growth on human blood agar and was not killed by heat, so that nothing was done which would in any way reduce its toxicity, and therefore its potency as an antigen.

ARTIFICIAL RESPIRATION IN THE NEWBORN.

THE method of artificial respiration here described has, in my experience, proved more certain and effective than any method now in vogue. It is, as will readily be understood, only applicable in the case of infants. I was led to elaborate it by noticing that a child who had inspired liquor amnii, and was held head downwards in order to free the respiratory passages, emitted a sigh when the abdominal contents pressed on the diaphragm. This led me to reverse the position of the infant to allow the lungs to expand.

The infant is held in the following way: The back of the neck lies on the palmar surface of the left hand, the occiput being supported in the hollow between the thumb and forefinger which grasp the mastoids. The right hand holds firmly both ankles of the infant from behind, so that the ulnar side is on the calves, the radial side at the heels. The infant is held with its long axis nearly vertical, at an angle of about 15 degrees, head upwards, and is then allowed to move quickly downwards by its own weight some two feet. The abdominal viscera fall towards the pelvis, the diaphragm is depressed and inspiration initiated. The infant is now lifted, feet first, to the right of the operator, so that it is now head downwards at an angle of 15 degrees to the vertical. It is again moved smartly downwards, head first, about two feet. The abdominal viscera, falling against the diaphragm, expel air from the lungs equivalent to expiration. This movement, at least to some extent, must also act as massage of the heart and so be a direct stimulant. The whole cycle is repeated about fifteen times to the minute, and the first movement will often elicit a sigh if not a more pronounced response. Needless to say all semblance of violence must be avoided.

OLIVE OIL SOFT SOAP AS A SHAMPOO IN PITIRIASIS CAPITIS.

THE exceedingly common affection called pityriasis capitis or dandruff is often unsuccessfully treated by the general practitioner owing to neglect of the great essential of systematic shampooing at regular intervals, and with the much advertised use of "shampoo powders" this disease is aggravated, especially in childhood, whereas if the scalp disease was cured in early life there would be no kindred eruptions of the face and trunk in adult life. The advantage of olive oil soft soap as it acts as an antiseptic, thereby which is confined and the

The soap is dissolved in hot water till a thick lather is obtained, with which the scalp is thoroughly rubbed. After shampooing rinse with plain warm water.

CONGENITAL DEFICIENCY OF THE DIAPHRAGM.

The following case seems worthy of record inasmuch as congenital muscular deficiency accounts only for some 10 per cent. of diaphragmatic herniae, and in this case the strangulation was not in the original sac, but in a diverticulum from it.

A child, aged 8 months, had been perfectly healthy until three days before admission to the Preston Royal Infirmary, when it commenced to vomit and the abdomen became gradually distended. There had been absolute constipation.

On examination after admission, the pulse was rapid and feeble, the lips were cyanosed, and the abdomen was very considerably distended, hard and drumlike, but nothing was palpable. *Per rectum*, the abdominal contents were bulging with the anterior rectal wall, otherwise there was nothing of note.

Laparotomy was immediately performed and the small bowel and ascending colon were found to be distended, while the descending colon was collapsed. The stomach was lying well up in the left side of the thorax, where there was apparent absence of the left dome of the diaphragm. The transverse colon had passed up beyond the stomach into a further sac and had become obstructed. The large bowel was reduced by the division of the constricting band, and the abdominal cavity was rapidly closed. Unfortunately, the patient, who was in a condition of profound toxæmia, survived the operation by a few minutes only.

On *post-mortem* examination there was found congenital deficiency of the left dome of the diaphragm; the left crus was present, and from it a few fibres passed round the left side of the oesophagus to join the anterior parietes slightly to the left of the middle line. Through the deficiency the peritoneum bulged into the thorax, where it was in direct contact with the basal pleura, the cardiac portion of the stomach reaching as high as the third costal interspace. At the apex of this sac the pleuro-peritoneal lining had given way to form a further sac in which the transverse colon had become strangulated. The heart was found lying completely to the right of the middle line. The left lung was collapsed and had apparently never functioned; it sank on being placed in water.

When the mother was questioned she recalled that there had been at times a bulging of the lower part of the left side of the thorax after feeds. I am indebted to Dr. Healey, honorary visiting surgeon, for permission to publish these notes.

Reports of Societies.

PRURITUS ANI.

At a meeting of the Subsection of Proctology of the Royal Society of Medicine on April 13th, with the President, Mr. W. E. MILES, in the chair, a discussion took place on pruritus ani, its causation and treatment.

Mr. J. P. LOCKHART-MUMMERY distinguished five groups of pruritus ani: (1) due to a general condition, such as glycosuria; (2) due to parasites; (3) secondary to some lesion of the anal region; (4) of old standing, with no local lesion discoverable; (5) paroxysmal pruritus. When a definite cause for the pruritus was discovered it was generally found to be one which produced a certain amount of moisture of a septic character, such as an ulcer. The removal of this, if the itching was of recent onset, gave permanent relief. Cases with a history dating back for more than two years were very difficult to cure, and even when a local lesion was discovered its removal seldom stopped the itching. He believed the change which took place in such long-standing cases to be fibrosis of the deeper layer of the skin, involving the nerve endings, and that it was brought about by a constant scratching and rubbing of the part. In 1912 Dwight Murray in America put forward the theory of a chronic streptococcal infection of the anal region, and the speaker believed this theory to be properly established. The first point in local treatment was strict attention to cleanliness and dryness. Powders

were better than ointments or greasy applications. If a local lesion—such as piles or ulcer—was discovered, it should be removed, and if such a lesion was not discovered the patient should be put under an anaesthetic and a complete examination made. X rays, applied with suitable screens, would cure about 20 per cent. of the bad cases, and the cure was generally permanent; two or three applications were usually sufficient. He had seen some very bad burns, and in one case an epithelioma of the anus, result from x ray treatment. When further measures were necessary there remained the operation first described by Sir Charles Ball in the *BRITISH MEDICAL JOURNAL* of January 21st, 1905. Ball's operation proved most satisfactory, but it was essential that the whole of the irritable area of the skin should be anaesthetized; the failures attributed to the operation were often due to missing some of the nerves. In performing the operation care must be taken to free the lining of the anal canal. The operation gave immediate relief and left no disability. Normal sensation returned completely within about six weeks. He had performed this operation in 59 cases. There had been a slight recurrence of itching in seven; in four of these this was cured by simple applications, and in the other three the operation was repeated, with complete success.

Dr. ARTHUR WHITFIELD said that a very large number of cases in adults—even middle-aged adults—were due to the oxyuris. The profession as a whole was not alive to the fact that threadworms were really very common. In one case, made temporarily quiet two years ago by x rays, the patient recently returned with a recurrence, and before recommencing treatment, he insisted that the patient should have thymol; on this being given, a large number of threadworms were produced. Cases almost always relapsed after x-ray treatment, and repeated doses lost their beneficial effect. When an obvious lesion was found and removed, a single dose of x rays might be useful. He believed that a great many burns and atrophies resulted from x rays. The most extravagant atrophy could be produced two years after the last dose had been given, even though no one of the doses had produced the smallest erythema or dermatitis. Among local applications greases should be avoided; lanoline was the worst grease that could be used, on account of its extreme tenacity and stickiness. He added that in a number of cases he had got the streptococcus from the anal tissue.

Dr. J. M. H. MACLEOD said that there were mild cases of pruritus ani which lasted a considerable time, and were due to causes of less importance than polypi or the presence of oxyuris in the rectum. Pruritus of a very troublesome character could be caused by congestion in the liver. A good many cases were due to general cutaneous affections. One case sent to him as pruritus ani proved, on examination, to be a case of psoriasis, with psoriatic patches on the knees and scalp. Another cause not to be lost sight of was ringworm, which was extremely common about the anal region. He had seen a couple of cases within the last year, sent to him as pruritus ani, which had the ringworm fungus. The rubbing and scratching caused secondary changes, sometimes a very marked thickening of the epidermis, and possibly the thickened epidermis pressed on the nerve endings and caused the spasms of pain which were so often found. He was not entirely favourable to x rays, but he had had a certain number of cases which did excellently, without recurrence so far as he knew. He gave usually three half-pastille doses, well spaced out.

Sir CHARTERS SYMONDS said that, local complications apart, the real basis of the trouble was a septic condition, and therefore he insisted on the utmost cleanliness and dryness after defaecation, and also wearing of some absorbent wool—salicylic wool had a special virtue—which must be frequently changed to prevent fiction and diminish the evil effects of moisture. He thought the best remedies to be silver preparations, not nitrate of silver, but argyrol and protargol in 10 or 20 per cent. solutions.

Dr. N. S. FRIZI said that before the cases came to the radiologist they should be investigated by a competent proctologist. Unless the cause was removed, the symptoms were bound to recur. When the cause had been removed or no definite cause had been found and the irritation continued, he thought that the theory of infection of the skin with the *Streptococcus faecalis* was very likely to hold good in such cases, and that here the treatment by

local measures such as α rays would be a sound proceeding. His experience was that cases were nearly always relieved by α rays at the commencement, but α rays could not be continued indefinitely. His results with radium had been rather more permanent than with α rays, although very similar otherwise. He had only used screened radium rays. If he was given the choice, and the irritation was not over too wide an area, he would prefer radium. He gave his doses of radium at intervals of six weeks, and he liked to give one further application after the disease had disappeared. There was still another procedure available for obstinate cases, supposing the patient refused to submit to Ball's operation, and that was the use of high frequency, applied with a vacuum electrode; in some cases this had a remarkable effect.

Sir CHARLES GORDON-WATSON said that there was one type of pruritus ani which he was inclined to regard not as surgical but as medical, like the pruritus associated with general constitutional diseases—namely, the pruritus occurring in the neurasthenic type of person. In such cases there seemed to be a strong hereditary tendency. In one case of father and son, both of whom were suffering from pruritus ani, he examined the son and found the dermatitis negligible and the anal canal perfectly healthy, with none of the fissures, ulcers, and haemorrhoids familiar in surgical cases. The surgical cases, he thought, ought to be divided into those which had an actual cause in the anus and those which had no marked disease or disturbance of the anus. When the cause was removed, if the pruritus had been only of short standing, the case could be cured for a certainty. In such cases ionization was of service, provided that all the elasticity of the skin had not disappeared. If the skin had not been changed into a kind of fibrous tissue but was still pliable, the cases responded well to ionization. In 28 cases treated by ionization (mostly zinc, but occasionally copper as well) every one experienced very great relief after the first treatment, and some needed no further treatment, though others went on to six or seven applications. Cases of paroxysmal pruritus were often to be referred to the neurasthenic class, but others were undoubtedly due to hypertrophied papillae. He had records at St. Bartholomew's Hospital extending over eighteen months of 86 cases of pruritus ani, in 53 of which there was one or more visible papillae. In the cases in which nothing was found but papillae the cautery was used, and in the majority a cure was obtained, in some cases certainly permanent after one application.

Mr. ASLETT BULWIN said that when local conditions had all been excluded, the bowel should be examined by the sigmoidoscope. Many of these cases had a catarrhal condition of the bowel, and that was the cause of the chronic dampness of the anus. He had seen many cases relieved by ionization with zinc sulphate. Dr. W. M. FELDMAN also suggested a catarrhal condition of the bowel as the cause. The condition appeared to be hereditary; at least he had one patient whose father suffered from pruritus ani in a mild degree and whose maternal grandmother had pruritus vulvae in a severe degree.

Dr. FRANK COKE referred to work on protein sensitization, and said that in recent American literature he found two cases tested by skin tests, one giving a big reaction to potato and the other to pork, and on removing these articles from the diet or returning the patient to it, the condition disappeared or reappeared accordingly.

The PRESIDENT (Mr. Miles) thought that the term "pruritus ani" was unfortunate, because it signified nothing beyond the fact of itching. They should discriminate between a purely local condition—that is, a local dermatitis—and a dermatitis which, although it might occur in the perineal region, was part of another disease, such as psoriasis or eczema. He had always considered the chief cause of pruritus to be dampness of the perineal region and this he attributed to the hypertrophied glandular elements in the skin of that region. An analogous condition was hyperidrosis of the feet, which set up intense itching. The treatment was careful drying. Dampness by macerating the skin gave opportunity for absorption. Hypertrophied papillae existed in the majority of cases of pruritus ani. One of the most productive causes of the condition was rectal constipation; when the faecal material was passing through the anal canal these hypertrophied papillae produced a spasm which cut off the act of defaecation and

left a certain amount in the bowel. A very large proportion of cases could be cured by (1) drying the anal region with suitable powders, (2) ensuring that when the patient went to bed he did not go with a full rectum.

Mr. LOCKHART-MUMIR, in reply, agreed that the anal papillae were often the cause of the trouble. As for sex incidence, the condition was rather more prevalent in men, but there was no great difference. He had tried vaccines, both autogenous and stock, and found them of no use.

ALTERATION OF PRESENTATION AND POSITIONS IN LABOUR.

The Glasgow Obstetrical Society met on March 16th, when Dr. ROBERT JARVIS gave a dissertation on "Methods of altering the presentation and positions before and during labour."

The operations were, he said, most frequently performed in the interests of the child, but were also often applied to facilitate labour and to spare the mother. He advocated examination a few days before labour to determine the position, which was then, as a rule, the same as that assumed during labour, if secondary face cases were excluded. Spontaneous alteration of position was very unusual at that late stage of the pregnancy, although not unknown. A transverse position found at such an examination should always be turned by external manipulations into a vertex or breech. In a primipara the external version should always be to a vertex, and this should be practised when a breech was found in a primipara. He had never tried to alter an occipito-posterior position to an occipito-anterior by external manipulations prior to the onset of labour, although this was possible. He made a plea for the more extensive use of abdominal palpation.

In occipito-posterior positions he did not approve of the rotation of the head by forceps, as he contended that the head was twisted on the neck while the shoulders were not turned. The treatment he advocated was manual rotation, aided by the external hand pushing the shoulder across, or, if this did not avail, the fingers of the vaginal hand were extended past the head, and the shoulder having been gripped, rotation was accomplished in this way. Rotation completed, he felt that it was advisable to apply forceps forthwith. Such cases ought not to be allowed to continue too long in labour. If the head was well flexed Milne Murray's straight axis-traction forceps, twice applied, were often satisfactory. In persistent occipito-posterior positions he advised attempt at rotation, trying first to one side, then to the other, on failure of which forceps delivery with the face to the pubis should be attempted despite the possibilities of perineal lacerations.

In face presentations it was advisable to leave all mento-anterior positions, except in cases where the head was very large, where it was advisable to convert to a vertex, at the same time rotating the occiput anteriorly. In all mento-posterior cases he thought that interference was justified. With a fully dilated os and unruptured membranes it was advisable to flex the head by manipulation *per vaginam*, and in cases with ruptured membranes manual dilatation of the os and flexion of the head was desirable before the face could become impacted. He advised immediate delivery with forceps after this manoeuvre. All these he had found easy to perform except in primary face presentations, in which he considered version the line of treatment to be adopted. Persistent mento-posterior positions could only be delivered as such if the child was very small. Attempts could be made to push the head up in these cases and perform flexion, but failing this craniotomy was to be recommended.

The typical parietal presentations of flat pelvis were interesting. The anterior parietal positions he left to mould, and then delivered with axis-traction forceps in Walcher's hanging leg position. The posterior parietal positions, fortunately the less common, presented a greater difficulty. These could be converted to anterior parietal presentations if got early and before moulding, but were difficult to maintain in the new position. Delivery by forceps immediately on correction, if possible, was the best method of treatment. If the correction could not be maintained he advised version.

Transverse presentations with ruptured membranes were treated, with fully dilated os, by performing podalic

version; in back anterior cases the lower leg was taken, while in back posterior cases the leg to be taken was the higher one, thus bringing the dorsum anterior for the completion of the delivery. In cases attended by retraction and impaction decapitation was the correct treatment.

In cases of breech presentations with extended legs he felt that the delay was due not to the splint-like action, but to the presence of a retraction ring. The hand was to be forced gently past this, a leg swept inwards, and the child delivered by the application of *vis a tergo*.

At the conclusion of Dr. Jardine's address Dr. W. D. MACFARLANE read a communication on "Caesarean section as a method of treatment in central placenta praevia."

CAESAREAN SECTION.

At the meeting of this Society on March 23rd Professor J. M. MUNRO KERR introduced a discussion on "The indications, limitations, and technique of Caesarean section."

A marked disproportion between head and pelvis and pelvic obstruction due to fibromyomatous or other tumour were, he stated, accepted as definite indications for Caesarean section. The advisability of its application in placenta praevia, eclampsia, toxæmia of the late months, cicatricial conditions of the vagina, congenital narrowing thereof, and delayed labour in elderly primiparae, was a debatable question until such time as surgical science could guarantee a sound uterine scar. The enlightened obstetrician would not be satisfied by sterilizing his patient, but would aim at the perfection of the scar, and to succeed in this he would have to give more careful consideration to such details as the suturing of the uterine wound, suture material, and, above all, the choice of a site in the uterine wall where the scar would be subjected to a minimum of strain. He referred to Dr. Eardley Holland's communication to the Royal Society of Medicine, and mentioned as of special interest the figures then submitted by Drs. Lindsay and Hewitt of the Glasgow Royal Maternity Hospital. From a review of ninety-four cases of Caesarean section, all unsterilized, they concluded that the liability to rupture in a succeeding pregnancy was 5.5 per cent., and that rupture occurred in 1.8 per cent.

The percentage of ruptures in a succeeding pregnancy could be reduced, he thought, but not in cases where the usual longitudinal incision was used. His reasons for not trusting to this incision were, first, that it was impossible to guarantee absolute asepsis; second, that during the puerperium the uterine muscle was in a state of autolysis, and thus interfered with healing; third, that the rough surface of the incised uterus did not approximate well, and permitted the collection of blood in small pockets thus formed; fourth, that the continual contraction and retraction of the uterus stretched the stitches, again permitting this pocket formation and blood collection. The necessity for the uterine sutures acting both as coaptors and haemostatic agents was another unsatisfactory state of affairs; they did not act efficiently in the latter capacity, failed to produce haemostasis, and healing was consequently imperfect. Above all, he attributed the weakness of the scar to the necessity to negotiate, at the first operation, a placenta placed anteriorly. In this condition the tissues were friable and over-vascular, the coaptation of the edges was particularly difficult, and blood collected between the stitch edges, with the result that a gutter formed on the inner surface of the uterus. In a subsequent pregnancy the membranes bulged into this gutter, formed a hernia, and ultimately led to rupture. These factors, he submitted, militated against the production of a reliable uterine cicatrix. He felt that the usual uterine scar could be improved; this could be done by such measures as practising prevention of sepsis, delivery of placenta *per vaginam*, to prevent the cervical portion of the membranes causing contamination; the operation should be performed at the most favourable time—for instance, at fairly full dilatation of the os in cases of contracted pelvis, or before labour in obstructive tumours; careful uterine suturing should be carried out, preferably in layers, catgut under the surface, fine silk or linen for the bulk of the muscle, and continuous catgut for the peritoneal surface, suturing during retraction, not contraction; there should be minimal massage of the uterus, and Fowler's position should be

employed during the puerperium, as recommended by Martin of Glasgow.

An alternative method of Caesarean section, giving, in his opinion, a more satisfactory scar, was the lower uterine segment operation. In this procedure the abdomen was opened in the mid-line and the uterus exposed, a transverse incision was made through the uterine peritoneum just above the bladder, which was then pushed down. A transverse incision was made in the lower uterine segment, stay sutures inserted at each end of it, and the child delivered. The wound was then closed, with catgut suturing for the mucous membrane, linen for the muscle, and catgut for tacking back the bladder. The cicatrix resulting was, he maintained, less liable to rupture. The advantages of this method were that, cutting through a less vascular area the haemorrhage was less, the cut surfaces were thin, and therefore more easily approximated with accuracy; these parts were at rest during the early days of the puerperium, and thus healing was facilitated; finally, the scar was not subjected to strain until the labour was far advanced. He noted also the infrequency with which one encountered the placenta in this area. In conclusion, Professor Munro Kerr submitted that this method was a promising one for the formation of a more reliable scar, and said he felt hopeful that it would ultimately produce a cicatrix which could be thoroughly relied upon to resist the strain of a subsequent pregnancy and labour. Already in four cases the scar had stood this test.

Dr. DAVID SHANNON expressed the opinion that conservative Caesarean section was performed too frequently and without due consideration to the weakened uterine which resulted therefrom. The lower uterine segment method offered a means of producing a safer scar. He had had the opportunity of examining the lower uterine segment after a normal delivery succeeding this operation, performed some time previously by Dr. Kerr, and had found no trace of scar. He himself had performed the operation on twelve occasions with very satisfactory results; five of these cases had been extensively and frequently examined before admission to hospital. He felt that there was scope for the operation in those cases which were suspected of being infected, which were, as a rule, terminated by that deplorable operation, craniotomy on a living child, with its attendant grave maternal mortality and morbidity. He had not experienced any difficulty in the operation, and had in one of his cases delivered a 10 lb. child.

Dr. J. NIGEL STARK explained that his experience of Caesarean section was confined to the conservative operation, and the results, immediate and remote, had been satisfactory. There were objections to the lower uterine segment operation, on account of the tendency to tear laterally in the case of a large child or a malposition, and on the score of the proximity of the uterine wound to the infected vaginal canal and cervix. A placenta encountered during this operation would be a serious difficulty.

Dr. DOUGLAS M. LINDSAY had assisted at several lower uterine segment operations, and only once had he noted difficulty. In this case no stay sutures were inserted at the lateral extremities of the uterine wound, and a tear into the right side of the cervix resulted with haemorrhage difficult to control. The investigation made by him in conjunction with Dr. Hewitt had proved that on occasion a thoroughly sound scar could follow the conservative operation. In that investigation there were examples of normal deliveries, forceps deliveries, and craniotomies in pregnancies following Caesarean section.

Dr. HEWITT referred to one particular case of that series. The patient's first child had been delivered by Caesarean section, her second was a seven months child delivered by forceps, her third was a breech delivery at term, complicated by extended legs, and when she again reached term she was delivered again by Caesarean section. He alluded to the variation in the thickness of the scar noted at the second operation and to the presence of adhesions. In one case he had had to cut a thick vascular band binding the uterus to the anterior abdominal wall.

Dr. R. A. LENNIE mentioned repeated Caesarean section; some of which exhibited no sign of scar and some the guttering described by Dr. Kerr. He would fear a similar guttering in cases of large children being delivered through the limited incision possible in the lower uterine segment. Referring to suture material, he quoted two cases in which a stitch sinus had followed two years after Caesarean section. In both cases the material had been

III and in a third case he had removed seven inches of silk *per vaginam* eighteen months after Caesarean section. He preferred three silk sutures with a deep and superficial catgut.

Dr. HENRY had realized the advisability of allowing labour to proceed far in order to have the lower uterine segment well developed. This made the operation more an emergency one than the conservative method, and the difficulty of the delivery of a large head. In one case he encountered a breech and his difficulty had been in deciding upon the size of incision to be made. It was advisable to deliver the uterus entirely from the abdomen to permit a hand being placed on the posterior cervical wall to aid the delivery of the head.

Dr. W. D. MACFARLANE expected that in "clean" cases the results following conservative Caesarean section would be as satisfactory as with the lower uterine segment method, while in "suspect" cases he thought the latter operation less satisfactory than Caesarean hysterectomy. As chairman he thanked Professor Keir for his excellent and suggestive paper, and expressed the hope that at some future date further records of the new method would be submitted.

NAEVI IN CHILDREN.

At the meeting of the Harveian Society on April 14th a lecture was given by Mr. DUNCAN FITZWILLIAMS on "Naevi in children, and their treatment," illustrated by many photographs and sketches.

Mr. Fitzwilliams said that he had careful notes of 700 cases, and that he must have seen 300 other cases of which he had no notes or only fragmentary ones. He defined a naevus as a blood-vessel tumour—just as much a tumour as a chondroma—which spread by the capillaries. Of his recorded cases, 56 per cent. were superficial, 35 per cent. transitional, and 8 or 9 per cent. subcutaneous. The number of deep naevi was, of course, difficult to estimate, for they were found in the viscera and in organs, where they must remain undiscovered during life. Naevi occurred twice as frequently in girls as in boys. It might be thought that the relatively high female incidence in the cases coming for treatment was due to the greater solicitude of the parents for appearance in the case of a girl, but he did not believe that such solicitude had any sex distinction in the case of infants so young. It was said that naevi were either present at birth or appeared during the first year of life; his experience, based on 645 cases, was that naevi were present at birth in 83 per cent., appeared in the first six months in 13 per cent., and appeared at a later date in 4 per cent. Very often when it was said that a naevus only appeared after birth, the fact was that it had not been mentioned by the nurse and had escaped the attention of the mother until she herself came to tend her offspring. Naevi occurred on the head and neck in 49 per cent. of his cases; on the trunk in 29 per cent., and on the limbs in 21 per cent. The long axis of the naevus was found always to be in the same direction as the nerve supplying the part.

If naevi were left to themselves he believed that some disappeared. In certain cases they would disappear by ulceration, while others ulcerated but did not quite disappear, leaving a spreading line of red capillaries. The cutaneous naevus should be treated without delay as soon as it was seen. If purely in the skin, it might be destroyed by CO₂ (carbon dioxide snow), being washed first with a little ether or iodine, and then subjected to the pressure of the snow pencil for thirty or forty seconds. If it was too big to be thus treated in one application the snow must be applied at more than one point, but care must be taken that the freezing areas did not overlap, and that they had unfrozen areas between them, if undue inflammation and scarring were to be avoided. Excision was of equal value to CO₂. An elliptical incision was made at right angles to the skin and into the subcutaneous tissue; the knife should never touch the naevoid tissue itself, or the bleeding, coming from spaces and not from vessels, would be difficult to control. Electricity was not very suitable for these cutaneous cases, and left more scarring than was necessary. In the transitional and subcutaneous type excision was the best method to adopt wherever possible, permitting removal of the tumour in one operation. The next best method was the use of the cautery, care being taken to destroy the growing edge of the naevus in

the first place. The destruction of naevi by electrolysis was slow and to some extent unreliable. Both poles should be inserted in the naevus, not one pole at another part of the body. The lecturer closed with a reference to naevoid marks, port-wine stains, and congenital dilatation of the capillaries, which were not true tumours. For these CO₂ or electrolysis might be tried, the latter method being carried out with only the negative pole under the skin and the positive pole, a flat disc soaked in brine, applied quite near. In some cases a long tenotomy or very thin knife might be inserted and the skin carefully under-cut.

A number of questions were asked at the close, and Mr. Fitzwilliams, in replying, remarked on the curious fact that children with naevi were mostly healthy children; in fact, he had never seen these children very ill with anything else. With regard to the possibility of vaccinating over the naevus, he had always understood that it defeated the object of vaccination if there was much bleeding; but he had vaccinated near the naevus, and when there was a good inflammatory result, a small naevus would disappear. He did not believe that a hereditary disposition to naevus had been established, though occasionally two or more members of a family were found to be affected.

Rebuelus.

THE INTERPRETATION OF SYMPTOMS.

SINCE the first edition, in 1909, of his *Symptoms and their Interpretation*,¹ Sir James Mackenzie has steadily continued his investigations into the mechanism and significance of the manifestations of disease, and accordingly this fourth edition, though arranged on the original plan and only thirty pages longer than the first, presents the results of his further studies, especially those from the St. Andrews Institute for Clinical Research, of which he is the director. The volume appears to have been passed for press last October, but it includes as an appendix, placed after the index, the author's paper on "The theory of disturbed reflexes in the production of disease," published in our issue of January 29th last, to which further reference will be made.

Sir James Mackenzie is a stern critic of loose thought, and in following his writings, as every practitioner of medicine should, the reader is apt to be haunted with the feeling that at any moment a cap may be presented that, unlikely as it might seem, exactly fits his head. Sir James's clear insight into the weak spots in the present state of medicine makes his message a wholesome if disturbing tonic to those who rest satisfied with its progress; for he insists that, though there is much laborious research and fresh symptoms are constantly being announced, the real need is for sound basic principles and the establishment of the laws governing the production of symptoms. Further, it often happens that what is supposed to be well known and commonplace is in reality so imperfectly understood that its true significance has been entirely missed. This applies particularly to the proper recognition of the mechanism of symptoms, in connexion with which "the laws of associated phenomena" should be given due weight, for in an illness there are various manifestations due to the causal agent disturbing many reflexes, and too often the most prominent of these symptoms is erroneously labelled as the primary morbid condition—for example, "the soldier's heart," or neurasthenia, is but one aspect of a diminished resistance to stimulation brought about by infection. A clearer knowledge of the mechanism of the less obtrusive symptoms would therefore facilitate the detection of the causal agent.

The study of symptoms is so ancient and familiar that it may appear a hard saying that at present symptomatology is in the same state of confusion as chemistry was before Dalton brought out the atomic theory, and that there is an urgent need for a classification of symptoms based on some law of nature that reveals the mechanism of their production. As the result of the recent conferences and work at the St. Andrews Institute, the conclusion—already foreshadowed in the early part of the volume—has

¹ *Symptoms and their Interpretation*. By Sir James Mackenzie, M.D., LL.D., F.R.S. Fourth edition. London: Shaw and Sons, 1920. (Demy 8vo, pp 319; 8 figures. 15s.)

been reached that the vast majority of the symptoms of disease are disturbances of normal reflexes; thus the muscular rigidity in abdominal disease is an exaggeration of the normal reflex which maintains the tone in these muscles. The two main reflexes due to cardiac failure are breathlessness due to insufficient blood supply to the respiratory system, and pain from exhaustion of the myocardium; in some conditions these may occur together, in others one only is prominent; thus in auricular fibrillation the respiratory reflex is readily produced, whereas pain is rare. In angina pectoris there are multiple reflexes—namely, sensory, in which pain and hyperalgesia affect the chest, arms, head, and neck; motor, secretory and respiratory. The pain is a viscerosensory reflex, due to a summation of stimuli; the sense of constriction is caused by spasm of the intercostal muscles, a visceromotor reflex, analogous to muscular rigidity in abdominal disease, best seen in the elderly.

This new "law" of the disturbance of normal reflexes may appear simple, but at this stage it is difficult to estimate its future influence on medicine. Sir James Mackenzie has done so much for the advance of medicine that his assurance that its application in practice and in research has already shown it to be of service must carry great weight.

MANSON'S TROPICAL DISEASES.

The establishment of the study of tropical diseases as a settled part of medical discipline may properly be held to date from the publication in 1898 of a textbook on the subject by Dr. Patrick Manson.² It was reprinted three times within a year of its first appearance; a new edition was published in 1900; and a third edition, revised by the author, who had in the interval become Sir Patrick Manson, appeared in 1903. The work has maintained its position as the best general textbook on the subject, and the familiar dumpy volume has been the companion of English-speaking doctors in all parts of the tropics. The new, seventh, edition shows many changes: a larger page is used, so that, though the new edition contains no greater number of pages than the sixth, it nevertheless contains a good deal more matter. It is edited by Dr. PHILIP H. MANSON-BAHR, who has introduced much new material; in its selection he has had the advantage of the help and advice of Sir Patrick Manson himself, so that the transition from the original author to the new editor is made in the best circumstances.

The contents of this new edition are well arranged. Section I deals with the fevers; Section II with general diseases of undetermined nature; Section III with abdominal diseases; Section IV with the infective granulomata; Section V with animal parasites and associated diseases; Section VI with diseases due to poisons, including snake-bite; Section VII with tropical skin diseases; and Section VIII with local diseases of uncertain nature. There are three appendices, dealing with medical protozoology, medical helminthology and entomology, and laboratory methods as applied to clinical medicine in the tropics. The separation of the purely technical descriptions of the protozoa, helminths, and insects from the clinical part of the subject is convenient, as it avoids fatiguing the reader when he is studying the first part of the book. After completing this, he can then go to the appendices for details. All the articles have been brought up to date and are clearly written. Special mention may be made of the account given of the new work on the etiology of yellow fever, of the new chapters on infectious jaundice, and of that on typhus. The highly interesting discussion upon the diagnosis of fevers in the tropics indicates how much the modern doctor must now know in the way of laboratory tests for the diagnosis of disease, and with what care he must approach the subject if he is to form a correct estimate of the condition he is called upon to treat. The chapter on schistosomiasis is excellent, as are also those on dysentery; modern methods, of course, permit the differentiation of the different forms of this disease with an accuracy unknown even a few years ago.

The criterion of a work on tropical medicine at the present day must be judged by the extent to which it will prove of value to the student as a textbook, because the standard of the examinations for the various diplomas in tropical medicine is now very high, and calls for a thorough, accurate and up-to-date knowledge of all the scientific matters included in this branch of medicine. Having read the work with great care, we may state that it fulfils this criterion satisfactorily; it may therefore be recommended to the student working for his examination as well as to the tropical practitioner.

In a work containing so many details some errors are inevitable, but in this book they are few. Maurer's dots are not the same as basophilic granules, and it is more correct to talk of tertian fever as occurring every third day than every second. Such slips as these can easily be corrected in subsequent editions. This edition is illustrated by many excellent diagrams, drawings and coloured plates. There are ten new plates in colour and upwards of 150 new figures in black and white. The wise liberality of the publishers in this respect adds very much to the value of the book. It is an excellent work in every way, and may be confidently recommended to all interested in tropical medicine.

THE LIPOIDS IN INFECTION AND IMMUNITY.

A CRITICAL review of the present state of knowledge concerning the part played by lipoids in infection and immunity is contained in a recent monograph by Dr. G. LINossier of Lyons,³ presented to the fourteenth French Congress of Medicine held at Brussels in May, 1920. As a result of his investigation of the literature, Dr. Linossier holds that it has still to be established that pure lipoids can act as antigens—that is, can give rise to specific antibodies; and also that the part they play in the defence has still to be adequately defined. This notwithstanding, it must be admitted that there is a strong probability that lipoids play a far more important part in both processes than is yet realized, and those who wish for a critical summary of the evidence at present available on this matter will do well to possess themselves of Dr. Linossier's suggestive little monograph.

ORTHOPAEDIC APPARATUS.

In *Gli Apparecchi Ortopedici* Professor DELITALA has produced a handbook on orthopaedic instruments which should prove useful to Italian-speaking students and practitioners. Professor Putti of Bologna, who has furnished a preface, says that in Italy the study of orthopaedic surgery, despite the good work due to it in the war, is in a backward condition. There are few universities where it is taught and few hospitals where it is practised. Textbooks on the subject in the Italian language are few (Professor Curcio's book on the same subject is the only one of any value). The production of *Gli Apparecchi Ortopedici*, under Professor Putti's direction, has done much to raise the credit of Italian orthopaedics, and this is to be followed up by a series of monographs emanating from the Rizzoli Institute at Bologna, of which that now under notice is the first to appear. Professor Delitala is well known as an orthopaedic surgeon, and in this small book he has produced a useful guide in which he lays down the principles upon which all sorts of orthopaedic appliances should be made, describes the mechanism of the best known forms; and gives directions for manufacture. As might be expected, not only are steel and leather appliances described, but those of celluloid and other materials such as plaster of Paris, of which the technique is well set forth.

It is refreshing to find a book published on the continent of Europe in which a good deal of importance is given to the hip and knee splints of H. O. Thomas. It has been the custom of French and German writers to ignore these exceedingly valuable appliances, to the use of which so much of the successful treatment of fractures in the British and American forces in the late war was due. Perhaps the best things in the book are the articles on celluloid corsets and splints stiffened with light steels;

² *Manson's Tropical Diseases*. Edited by P. H. Manson-Bahr, D.S.O., M.A., M.B.C.P. (Lond.). Seventh edition, revised. New York: Cassell and Co., Ltd. 1921. 27 plates. 30s. net.

³ *Les Lipides dans l'Infection et dans l'Immunité*. Par le Docteur G. Linossier. Paris: F. et J. B. Baillière et Fils. 1920. (Up 103 10 francs.)
⁴ *Gli Apparecchi Ortopedici*. By F. Delitala. Bologna, L. Cappelli. 1921. (Cr. 8vo, pp. 290 + xii; 248 figures. £1.)

a novelty is the use made of vulcanized rubber for splints for pseudarthrosis and flail-joint and other disabilities of the upper extremity. In this connexion Professor Delitala makes the interesting statement that, although caoutchouc will adhere closely to only one metal—namely, 18 carat gold—he has found that it will hold closely enough to aluminium, and that this metal, when entirely enclosed in vulcanized rubber, forms the best means of reinforcement. For the lower extremity celluloid and steel are preferred. In an appendix an interesting illustrated account is given of the workshops of the Rizzoli Institute, which cover a space of 1,500 square metres, a little distance from the main buildings.

It cannot be said that Professor Delitala's monograph is of equal value to the excellent little book of Dr. Ducrequet, *La Prothèse Fonctionnelle des Blessés de Guerre* (reviewed in our columns June 28th, 1919, p. 800), but it approaches to it, and supplies in the Italian language a want which has not yet been adequately met in the English.

"THE EXTRA PHARMACOPOEIA."

THE first volume of the new edition of *The Extra Pharmacopoeia* appeared last June, and was reviewed in this JOURNAL on July 17th, p. 78. The second volume of the new edition, which is about to appear, is considerably larger than the corresponding volume of the last edition, but though it contains over 700 pages, yet it is of convenient size, and the increase in bulk is in part due to the inclusion of a complete index for both volumes. In the last edition the first volume contained the index for both parts, but the new arrangement of adding an index to each volume is a great convenience in a work of this nature, which is specially intended for rapid reference.

The first third of the volume deals with the chemistry of drugs, and contains information about tests for purity, methods of preparation, and tests for activity of drugs, together with tables of organic analysis. Analytical methods of special interest in public health are described in another part of the book, and descriptions are given of the methods of analysis of water, milk, and butter. The antiseptic power of disinfectants and the methods by which comparative figures are obtained are also described; under the heading "Nutrimenta" the bleaching and the adulteration of flour is described.

The sections of chief interest to medical men are those dealing with special methods of treatment and the descriptions of the chemical and bacteriological methods used in practice. All the latest methods of analysis of the blood, urine, faeces, and stomach contents are described, and full information is given concerning the preparation of dyes and culture media and the identification of micro-organisms.

The different portions of the volume are of special interest to different classes of medical men, but the following subjects may be specially mentioned because they are of general interest, and the recent information concerning them is given very fully: the therapeutic action of x rays, electric currents, and ultra-violet light; the physical chemistry and therapeutic action of radium, and radioactive salts; the various chemical and physiological methods for the standardization of digitalis; the tests for renal function; and the determination of the reaction of the blood.

The book also contains a variety of other information which it is difficult to classify—such information as proprietary medicines and the composition of mineral waters, a list of British health resorts, and glossaries of medical terms in eight foreign languages. Moreover, abundant references are given to clinical and also to scientific literature.

Enough has been said to show how wide is the range of subjects covered in this volume. The authors have succeeded in compressing into one volume an excellent summary of all the clinical methods in general use, including all the most recent advances, and therefore their work is of particular value to those who desire concise information concerning these methods.

The special advantage of the book is that it contains

easily accessible information about most of the laboratory tests used in clinical practice. The chief improvement that we can suggest is that the sections might be arranged in a somewhat more logical sequence; for example, the methods of analysis of blood, urine and faeces are given together, but the analysis of gastric contents is dealt with elsewhere; again, the analysis of water is separated from that of butter and milk by a description of the contents of mineral waters and a list of health resorts. The index is, however, very full, and therefore these irregularities in arrangement are not of any great importance.

NOTES ON BOOKS.

THE address which the Hon. JOHN W. DAVIS, the late Ambassador of the United States, gave last January at University College, London, on *The Constitution of the United States*, has now been published from the University of London Press.* In this discourse is traced the history, modification, and development from its British sources of the American Constitution—"the most wonderful work ever struck off at a given time by the brain and purpose of man," as Gladstone described it.

In the seventy-four short poems brought together as *Thoughts of a Nature Lover*† Dr. KENNETH ROGERS shows a talent for verse that he has hitherto hidden from the world at large and a certain touch of pathos and meditative reflection on the fleeting years since he was at Temple Grove, Marlborough, and St. Bartholomew's Hospital. This is especially seen in the lines "To Savernake Forest," which he naturally regards "with a love unchanging from a vanished day," in the biographical "Retrospective," and in "Farewell to an old friend." In addition to the main theme, the joy of Nature, there are verses on various aspects of human nature, on the events of the war, and translations from the French and Italian. In "The captured German guns in the Mall" there is a pretty conception of these "spectres from an evil dream" which

"... children now, with laughing joys,
Delight in them as wondrous Toys."

THE VOLUNTARY PRINCIPLE IN LONDON.

INTERIM REPORT OF THE KING'S FUND POLICY COMMITTEE.

IN an article in the JOURNAL of February 5th last we gave a full account of the report by the Executive Committee of King Edward's Hospital Fund for London upon the policy to be recommended for the preservation of the voluntary system of hospital management and control. In accordance with that report the President and General Council of the King's Fund, on January 26th, passed a series of resolutions and appointed a special Policy Committee with the instruction to work out details of the policy and to take steps to recommend it to the Government, to Lord Cave's Committee of Inquiry, to the hospitals, and to the public. The Committee consists of Lord Stuart of Wortley (Chairman), Sir Cooper Perry, Viscount Burnham, Lord Somerleyton, Sir Frederick Fry, and Sir Alan Anderson.

At the last meeting of the President and General Council, held on April 12th, the Policy Committee presented an interim report, dated April 4th, which has now been issued. This states that written and oral evidence was submitted to Lord Cave's Committee in amplification and support of the statements contained in the Executive Committee's report and the resolutions of Council,† together with a further analysis of the figures supplied to the Fund by the hospitals in January.

Financial Position at the end of 1920.

While the income of the London hospitals had steadily risen since 1913, due mainly to the growth of voluntary contributions, the expenditure increased at a far greater pace. Thus the aggregate income from normal sources in 1920 was £2,447,000, while the expenditure was £2,841,000, leaving a deficit of £394,000, or about 14 per cent., on the

* *The Extra Pharmacopoeia*. By W. Harrison Martindale, Ph.D., Ph.C., F.C.S., and W. Wynn Westcott, M.B. Lond., D.P.H. Vol. II. Sixteenth edit. n. London: H. K. Lewis and Co., Ltd. 1921. (Fcap 8vo, pp. 638 + 32. 17s. 6d. net, 18s. post; free throughout the world.)

† Copies of the Policy Committee's Interim Report and of the thirteen resolutions passed by the General Council can be obtained from King Edward's Hospital Fund for London, 7, Walbrook, E.C.

working of the year. Emergency grants from the King's Fund and the National Relief Fund almost exactly wiped out that deficit, but those sources of income are non-recurrent. Accumulated bank loans amounted to £544,000 on December 31st, 1920. The individual differences between income and expenditure varied widely, of course, and from its study of these the Committee infers that the problem, though serious enough at the hospitals which have large deficits, ought not to prove insoluble.

Alternative Remedies.

Accepting the decision of the Council that voluntary contributions would need to be supplemented, at all events temporarily, by some other sources of revenue, the Committee has considered the various alternatives put forward. No final conclusions have been reached, but a solution is at present being sought along the following lines:

"The supplementary income must be adequate to meet the present deficit; it must be capable of expanding to meet the cost of necessary extensions and developments; and it must not endanger voluntary management or the interests of the sick poor."

The choice could be narrowed down to two alternatives: (a) Payment in some form or other for specific work (which might include payment by means of voluntary or compulsory insurance); or (b) assistance from public funds proportioned in some way to voluntary contributions.

On the subject of payment by a method of voluntary insurance the Committee makes the following reference to the Sussex scheme, of which an account was given in our issue of January 22nd, 1921, p. 129:

"It is obvious that many patients who cannot pay during illness could, nevertheless, afford to make provision for hospital treatment by some form of voluntary insurance. A comprehensive scheme, associated with the name of Dr. Dill, has begun to be put into operation in Sussex; and a Committee of the British Medical Association has recommended its adoption, with modifications, by the hospitals of London. We are not at present prepared to endorse this scheme, especially as it has not yet been considered by the Hospital Saturday Fund."

After discussing the first alternative (a) in some detail, the Committee considers that both forms of insurance—voluntary and compulsory—should be thoroughly explored, in order to see whether the problem could be solved if the voluntary subscriptions of the charitable public were supplemented by a graduated system of patients' payments from those able to pay at the time of illness, and by insurance on the part of those who are unable so to do; the hospitals agreeing to limit free treatment, except in emergencies, to those unable either to pay or to insure.

The Committee has not as yet given consideration to the second alternative (b) of State or municipal assistance to encourage voluntary contributions. It thinks, however, that the principle of aid proportioned to voluntary contributions might have the advantage that it could be put into operation rapidly. Hence the possibilities of this alternative, either as a temporary expedient or as a permanent way of encouraging the maintenance of the voluntary system, should be investigated.

Emergency Assistance.

In view of the likelihood of a repetition of last year's crisis in hospital finance, the Committee notes that but for the emergency distribution of a quarter of a million by the King's Fund, some important London hospitals might have been obliged to close down or come on public funds. Should emergency aid again become necessary, it strongly deprecates any further depletion of the reserves of the King's Fund, except possibly by an advance with repayment guaranteed. Some other method, it is considered, would have to be found. One way would be by Government aid in some form wholly outside the sphere of permanent remedies; for instance, a payment towards the loss borne by the voluntary system in the treatment of service patients during the war. Another way would be by Government aid as an instalment of, or as an advance in anticipation of, some permanent remedy adopted by the time the crisis arose, but not yet worked out in detail or not yet put into full operation. Or, again, the recommendation already made by Lord Cave's Committee regarding surpluses now in the hands of the approved societies under the National Insurance Acts might possibly yield enough money in time to avoid any immediate collapse.

THE USE OF ALCOHOL IN MEDICINE.

At the annual meeting of the Society for the Study of Inebriety on April 12th, Sir ALFRED PRANCE GORDON presiding, a discussion took place on the use of alcohol in medicine.

Dr. H. H. DALE, F.R.S., in an opening address, said that it was difficult in any discussion concerning alcohol to preserve a perfectly objective and scientific attitude, but he thought they could agree that their views on the social significance of alcohol had no bearing on its status as a remedy. It ought to be possible to hold the opinion that alcohol in daily life was harmful and at the same time feel no obligation to discredit alcohol as a drug when properly prescribed. A great deal of unnecessary heat had been wasted over the question whether or not alcohol was a food. The question was primarily one of nomenclature. If by food was meant a substance which by its combustion in the body could liberate energy, the claim of alcohol to rank as a food in that sense was beyond dispute. But that did not in the least imply that alcohol was a proper or desirable food for a healthy man; that must be determined on other grounds, and he doubted whether anyone would now be found to advocate the replacement of so much carbohydrate or fat in the normal diet by alcohol. But in the case of the sick the conditions were different. It became in that case relevant to remember that alcohol differed from all the other constituents of diet, save glucose, in that it was ready for absorption and use without preliminary digestion. In severe febrile and acutely toxic conditions in which the secretion of the digestive ferments was more or less in abeyance, it did seem that alcohol might have some advantages as an emergency food; and the effect of alcohol on the brain and central nervous system, which forbade its use as a proper substitute for other foods in health, did not in his opinion contraindicate its use in the case of the sick. Its action in weakening the critical judgement and blunting the fine edge of sensibility, however much this might lead to the lowering of efficiency in the ordinary business of life, might be and in many cases was all to the good when dealing with a restless, anxious, and fever-stricken patient. The sedative effect of alcohol might be as important as its food value in such cases. In one other direction alcohol might be regarded as an abnormal food—namely, in the preliminary period of starvation in the modern treatment of diabetes, when it was very necessary not to give the patient anything which he could possibly convert into sugar. The one source of energy which could be given without vitiating the treatment was alcohol. Dr. Mellanby had told him of one business man who had had to give up his work on account of diabetes because a diet low enough to keep his urine free from sugar was insufficient for the energy needs of an active life; but that patient was able to resume his work and again lead a normal existence as the result of adding to his diet a measured, properly prescribed ration of alcohol, which, alone of all possible foodstuffs, supplied the missing units of energy without leading to renewed excretion of sugar. But such cases had nothing whatever to do with the old port wine tradition. The prescription of alcohol for convalescent or weakly patients who were able to take ordinary foods was a very much more doubtful and difficult subject. From the experimental point of view he found it hard to believe that alcohol had any special value in such conditions, except in so far as by making the patient more comfortable, and rendering him less sensitive to the tedium of convalescence, it might indirectly improve his appetite, and thereby improve his digestion and assimilation. He had been told that the cases in which the giving of alcohol during convalescence had led to the alcohol habit were few or unknown, but that was only a small aspect of the subject; it was a much more serious danger that the casual recommendation of stout or port wine in such circumstances, on the basis of a not yet extinct faith in its efficacy for building up the system, might reinforce with the weight of medical opinion the natural desire of the laity to believe that what they liked was good for them.

As for the supposed value of alcohol as a stimulant, the verdict of experimental pharmacology had for some years been clear. He believed that the basis for the idea that alcohol was a cardiac and respiratory stimulant was the reflex effects of its action on the buccal and oesophageal

CURRENT NOTES.

The Annual Meeting at Newcastle.

The arrangements are gradually going forward for the eighty-ninth Annual Meeting of the British Medical Association to be held next July at Newcastle-on-Tyne. The Association has twice before met in Newcastle; the first occasion was in 1870, with Dr. Edward Charlton as president, and the second in 1893, under the presidency of Sir George Hare Philipson. The proceedings will open this year on Friday morning, July 15th, when the Representative Body will begin its annual meeting, the session being continued on the three following weekdays. Council meetings have been provisionally fixed for the mornings of Monday, July 18th, and Wednesday, July 20th. The statutory annual general meeting will be held at 2 p.m. on Tuesday, July 19th, on which day the social and scientific business of the annual meeting will commence with the delivery by Professor David Drummond of his Presidential Address to the Association at 8 p.m. The sectional meetings for scientific and clinical work will be held, as usual, on the Wednesday, Thursday, and Friday; the mornings from 10 a.m. to 1 p.m. being given up to discussions, and the afternoons from 3 to 4.30 o'clock to clinical and laboratory demonstrations, of which a special feature will be made, as was the case at Cambridge last year. The list of sections and their presidents is printed below. The first five sections will meet on July 20th, 21st, and 22nd; the six following sections on two days each; and the remaining six sections on one day each.

Medicine: Professor Thomas Beattie.
Surgery: Professor J. Rutherford Morrison.
Pathology and Bacteriology: Professor Stuart McDonald.
Preventive Medicine with Industrial Diseases: Sir Thomas Oliver.

Orthopaedics and Diseases in Children: Mr. A. H. Tubby.

Neurology and Psychiatry (July 20th and 21st): Professor A. W. Macintosh.

Obstetrics and Gynaecology (July 21st and 22nd): Professor R. F. Ranken Lytle.

Ophthalmology (July 21st and 22nd): Professor J. D. Wardale.

Oto-Rhino-Laryngology (July 23th and 21st): Dr. G. William Hill.

Physiology, Pharmacology, Therapeutics, and Dietetics (July 20th and 21st): Dr. H. H. Dale.

Veneral Diseases (July 23th and 21st): Colonel L. W. Harrison.

Ambulance and Red Cross (July 20th): Sir James Cantlie.

Dermatology (July 21st): Dr. J. Farquhar Christie.

Medical Sociology (July 22nd): Sir Jenner Verrall.

Proctology (July 20th): Mr. J. P. Lockhart-Mummery.

Radiology and Electro-Therapeutics (July 22nd): Dr. Robert Knox.

Urology (July 22nd): Mr. J. W. Thomson Walker.

There will be religious services on Tuesday, July 19th, at 5 p.m. On Wednesday evening at 8 o'clock Sir Thomas Oliver will give an address on Industrial Diseases, and on the same day the Secretaries will hold their annual conference and dinner. The Annual Dinner of the Association will be held on Thursday evening, July 21st, and on Friday Professor Arthur Keith will deliver the Popular Lecture at 7.30 p.m. Saturday, July 23rd, the last day of the meeting, has been set apart for excursions to places of interest in the neighbourhood. Articles on the history, institutions, and industries of Newcastle have appeared in the JOURNAL of December 11th, 1920, March 12th and April 16th, 1921, and information about hotel accommodation was given in last week's SUPPLEMENT. The Honorary Local General Secretary is Mr. R. J. Willan (6, Kensington Terrace, Newcastle-on-Tyne).

Motions for the Annual Representative Meeting.

As will be seen in another column, motions of which two months' notice are required by the By-laws must be in the hands of the Medical Secretary by April 30th. Motions which do not propose any alterations of Articles or By-laws, nor any material alteration in the policy of the Association, are in order any time before the Annual Representative Meeting (which opens on July 15th at Newcastle), but the earlier they are received the greater publicity they will get. So far the only motions received which would involve any alteration in policy are one which suggests the formation of a "student class" of members with a reduced subscription, one proposing that the collective opinion of the profession can only be expressed by a body directly elected by the profession, and one suggesting that the Association should appoint representatives to the Federation of Medical and Allied Societies. Full notice of these and of all other motions received will be given in the SUPPLEMENT on or before May 14th. Those Divisions which have ideas for the improvement of the constitution, policy, or working arrangements of the Association are invited to formulate them and send them to the Medical Secretary.

Tour of Yorkshire Divisions.

The Medical Secretary has made arrangements to visit the following Divisions of the Yorkshire Branch during the last week in April:

Wednesday, April 27th, Leeds Division at Leeds, 3.30 p.m.

Wednesday, April 27th, Halifax Division at Halifax; evening meeting.

Thursday, April 28th, Barnsley Division at Barnsley, 4 p.m.

Thursday, April 28th, Huddersfield Division at Huddersfield; evening meeting.

Friday, April 29th, Scarborough Division at Scarborough, 8 p.m.

Medical Cinematograph Exhibition.

A cinematograph exhibition of medical and surgical films was held on March 30th, at Exeter, under the auspices of the Exeter Division of the British Medical Association.

The following films were exhibited: Cholecystectomy, appendicectomy, gastro-enterostomy, hysterectomy, undescended testes, tibial bone graft, wound sterilization (Carrel). Over 100 members attended, many coming from distant towns, and the greatest interest was shown in the demonstration.

Association Notices.

ELECTION OF COUNCIL OF ASSOCIATION, 1921-22.

A LIST of the Groups of Branches in the United Kingdom for election of twenty-four Members of the Council, 1921-22, and **Nomination Form**, were published in the SUPPLEMENT of March 12th (p. 73). The **Nominations** must be in the hands of the Medical Secretary **by May 16th**.

The result of the election for Members of Council by the Groups of the Oversea Branches was published in the SUPPLEMENT of February 19th, 1921.

ELECTION OF REPRESENTATIVE BODY OF ASSOCIATION, 1921-22.

Constituencies in Representative Body.

THE Council has finally grouped the **Home Divisions** for election of the Representative Body, 1921-22, in the same manner as for 1920-21, except that the Caithness and Sutherland Division of the Northern Counties of Scotland Branch, and the Rotherham and Sheffield Divisions of the Yorkshire Branch have been made independent Constituencies.

As intimated to all the **Oversea Bodies**, the Council has made each Oversea Division and Division-Branch an independent Constituency.

Election of Representatives and Deputy-Representatives.

THE REPRESENTATIVES AND DEPUTY-REPRESENTATIVES in the Representative Body must be elected not later than **June 17th**, and their names notified to the Medical Secretary **not later than June 24th**. The Annual Representative Meeting at Newcastle begins on July 15th.

Special attention is drawn to the fact that the election of Representative(s) and Deputy-Representative(s) may, at the discretion of the Constituency, be carried out by General Meeting of the Constituency, or by postal vote.

MOTIONS FOR ANNUAL REPRESENTATIVE MEETING, NEWCASTLE, JULY, 1921.

NOTICES OF MOTION by Divisions, Constituencies, or Branches, for the consideration of the Annual Representative Meeting of the Association, commencing Friday, July 15th, 1921, proposing to make any addition to, or any amendment, alteration, or repeal of, any Article or By-law, or to make any new Article or By-law, or proposing material alteration of the policy of the Association in matters relating to the honour and interests of the profession or of the Association, must be published in the BRITISH MEDICAL JOURNAL SUPPLEMENT not later than May 14th, and for this purpose should be received by the Medical Secretary **not later than April 30th**.

BRANCH AND DIVISION MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—A general meeting of the Division will be held at the Metropolitan Hospital to-day (Friday, April 22nd), at 9.15 p.m. Agenda: Election of officers for ensuing year. Representative for Annual Representative Meeting. Other matters.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A meeting of the Lewisham Division, to which all medical practitioners of Lewisham are invited, will be held at 45, Laurie Park Road, Sydenham, S.E.26, on April 26th, at 8.30 p.m., when the chair will be taken by Dr. G. W. Charsley. Agenda: Discussion of the Report of the Consultative Council (SUPPLEMENT, October 16th, 1920). Discussion re Municipal Clinics of Points in Letter from Honorary Secretary of Willesden Division in the BRITISH MEDICAL JOURNAL of January 29th, p. 171. Drs. Charsley and Gilchrist will report a case of pyaemia, and show specimens.

METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.—The annual meeting and dinner of the Division will be held on Thursday, May 19th.

Meetings of Branches and Divisions.

EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION. A MEETING of the Division was held at Newtown St. Boswell on April 6th, when Dr. A. D. FLEMING, Chairman of the Division, presided.

The annual report and financial statement were presented and approved.

The report of the Council to Divisions and the Representative Body regarding the steps to be taken whereby the Association may become in part a federation was submitted, together with a circular on that subject from Dr. E. R. Fothergill. Dr. A. J. CAMPBELL referred to the desire of the authorities that there should be some body to represent authoritatively the views of the medical profession, and expressed the opinion that the public did not fully appreciate the extent to which the British Medical Association represented the profession.

After discussion, the following resolution was adopted:

That while this Division does not object to a federation of any bodies composed exclusively of medical practitioners, it objects to federation with bodies not consisting exclusively of registered medical persons.

The Scottish Consultative Council's Report having been issued to members was taken as read. The HONORARY SECRETARY submitted a resolution that had been passed by the Edinburgh Branch. The discussion opened with some remarks as to the exact meaning of various parts of the scheme, and particularly as regards the persons who would be entitled to benefit under it. Drs. MUIR, BLAIR, MCLAGAN, CULLEN, HENDERSON, and others contributed to the discussion. It was soon apparent that members considered that the scheme would entail financial liabilities far beyond anything that was likely to be met in the present state of public finances, and that it was only possible to discuss the various proposals on the assumption that the scheme would be financed irrespective of its cost. The questions asked by the Scottish Committee were generally answered in the affirmative, it being deemed that the majority of the proposals made in the scheme were in themselves desirable if they could be paid for. The questions answered in the negative were Nos. 4 and 13.

LANCASHIRE AND CHESHIRE BRANCH: ROCHDALE DIVISION.

THE annual meeting of the Rochdale Division was held at Rochdale on April 6th, when Dr. GEDDES was in the chair. The annual report showed that the membership had increased by three during the year; the average attendance at meetings was ten. The financial statement showed a small deficit.

The following officers were elected:

Chairman: Dr. Bateman. Vice-Chairman: Dr. Geddes. Secretary and Treasurer: Dr. James Melvin. Auditor: Dr. Harris. Representative in Representative Body and to Branch Council: Dr. S. T. Lord. Deputy Representative: Mr. James Melvin.

METROPOLITAN COUNTIES BRANCH (EAST HERTFORDSHIRE DIVISION).

A MEETING of the East Hertfordshire Division was held at the County Hospital, Hertford, on April 13th, when Dr. A. E. GILES (London) delivered a most instructive lecture on "Pessaries versus Operation in the Treatment of Displacements." Considerable discussion followed, in which most of those present took part.

SUFFOLK BRANCH.

THE spring meeting of the Suffolk Branch was held at Holesworth on April 13th, 1921. The following resolution was adopted:

That having in view the necessary Division, the Branch Council asks consider some means of financing percentage of members is high. Dr. CHARLES (Ipswich) showed an interesting series of pathological specimens. Dr. P. L. GIUSEPPI (Felixstowe) read a paper on some developments in the treatment of urethral strictures. Dr. WOOD (Woolpit) opened a discussion on thyroid therapy in private practice, and Dr. MITCHELL (Brookford) opened a discussion on the treatment of common colds and catarrhal conditions of the upper respiratory tracts.

UGANDA BRANCH.

THE annual meeting of the Uganda Branch was held at Mulago, Kampala, on January 15th, when Dr. COOK was in the chair.

The following officers were unanimously elected for 1921:

President: Major Wiggins. P.M.O. President-elect: Major Keane. D.S.O. Vice-President: Dr. Stanley Smith. Honorary Secretary and Treasurer: Captain Owen.

Dr. Peacock, who had been elected Honorary Treasurer and Secretary at a meeting held on July 22nd, 1920, was unable to act, as he had been transferred to an out-station. The Model Rules were accepted with slight modifications. It was agreed that no action should be taken with regard to modification of by-laws regarding adjudication of ethical cases (Articles of Association 10, b). It was noted with regret that Dr. J. A. MacDonald has been unable to visit Uganda. Major Wiggins, on behalf of the members, welcomed Dr. Case, the only lady member in the country. Votes of thanks to the retiring President, Honorary Secretary, and other officers, and to Dr. Baker and Major Keane for entertaining the members at Mulago, were passed unanimously. A discussion on blackwater fever took place during the afternoon.

MEETINGS OF THE PROFESSION.

HASTINGS.

THE Medical Secretary addressed a meeting of the medical profession of Hastings, and district at the Albany Hotel, Hastings, on Friday, April 15th. The meeting was called by Dr. A. M. Duddy, Secretary of the Sussex Branch. There were fourteen present, Dr. J. D. Huxley of St. Leonards being in the chair.

Dr. Cox said that his main object in attending the meeting was not so much to discuss the subject on which he had promised to address them but to find out whether the medical profession in Hastings and district was dead or only sleeping. There could be only two explanations of the prolonged disorganization of the medical profession in that district—either they were so well off that they had no grievances or they were unable to look far enough ahead to see that a local profession without proper organization was in a dangerous position.

He went on to deal with his subject, which was "How much more State medical service does the medical profession want?" He recounted the long list of appointments part-time and whole time, which involve the employment of the medical profession by the State, either centrally or locally. He said that there were about 1,000 more whole-time practitioners in the British Islands in civil employ than there were in the Navy, the Army, the Air Force, and Indian Medical Service combined, and when it came to part-time employment a considerable majority of medical practitioners were doing some form of State medical service. Moreover, a great many of these services had been introduced at the distinct invitation of the profession itself, and the medical profession was divided, and always would be divided, as to how far other services now left to private practice ought to be organized by the State. For example, many practitioners believed that the average wage earner could not be expected to provide himself with the services of specialists and institutional treatment, and that therefore the State ought to organize the provision of such services. Dr. Cox's experience led him to believe that the profession as a whole was convinced that a whole time State medical service would be a bad thing for the profession and worse for the public, but he pointed out that if, as had been suggested by many practitioners themselves, the dependants of the insured were ever included in the National Insurance system there would be little difference between that position and a whole time service. So long as the doctor had some work outside the State system and so long as the patient could choose his doctor there would be some difference, but it would not be great if the insured persons and their dependants were all medically provided for by the State. He did not believe such an extension was within measurable distance, mainly because the country could not afford it, but also because there were not sufficient doctors in the country to do the work properly if the dependants made the same demands on the doctors as the present insured persons did. If such an extension should come, the best hope of the profession would lie in the fact that the system placing on the doctors themselves the system properly. So long as the liberty of the doctor and his fees be seriously damaged.

Dr. Cox said that he threw out these reflections for discussion, not because he had any particular cry to advance, but because it was necessary that the profession should keep its eye on the tendencies which affected it and make up its mind which way it wanted those tendencies to move. His own personal opinion was that there was a great gain to the community in direct payment by the person who got a thing, whether it was medical attendance or boots. It encouraged self reliance in the citizen and enabled him to speak his mind and act freely as regards the person who supplied the boots or the medical attendance in a way he could never do if the articles were supplied through a State store or a State system. Therefore he urged on the profession to stimulate every possible method of supplying what the public wanted in the medical line, other than State provision. As an instance of what the profession could do in this way, he pointed to Dr. Gordon Dill's scheme, which as an example of initiative and goodwill was worth any amount of encroachment on private

or how much less State medical service the profession wanted because the question would not be settled by them. But this ignored the great social and political power of the profession. He entirely disagreed with those who belittled the political influence of the medical profession. His official experience had convinced him to the contrary, and there had never been a more striking proof of this than the recent discussion over the Dangerous Drugs Regulations. When the doctors really got busy and showed their Members of Parliament that they were seriously interested in this matter it was most striking to see how anxious the members were to meet the wishes of their medical constituents if they possibly could. They realized, if the doctors themselves did not, what an important factor the doctor could be in political life if and when he chose. Dr. Cox ended by urging those present to reconstitute the Hastings Division and to make it a useful unit in the machinery of the Association. If they were really contented in unprecedented state of things, it was their duty to cast their ideas into the common pool. But he felt sure the time would come when they would have their own local difficulties, and would be glad to know that they had behind them a national association.

THE CHAIRMAN, Dr. F. W. SKINNER of Rye, Dr. G. LOCKER, Dr. P. B. L. WIS, Dr. W. MUIR SMITH of Eastbourne, and others joined in the discussion. They all agreed on the necessity for unity and organization, and deplored the tendency to the employment of whole time practitioners for work which private practitioners could do quite well. Dr. Muir Smith pointed out that this tendency could be reversed if the doctors would only take the trouble. At Eastbourne, where they had a very active Division, they had got nearly all the work of the local authorities into the hands of private practitioners, and they were on the best terms with their local authorities. In fact, they had shown that the profession could by its unity, and having the national organization at its back, get almost anything in reason that it asked for.

A small committee was appointed to attempt to revive the Division, and Dr. Hessey consented to act as convener. The meeting closed with a hearty vote of thanks to Dr. Cox.

INSURANCE.

CORRESPONDENCE.

"Availability" in Emergency Cases.

SIR,—In the giving of "immediate" treatment in "emergency" cases to an insured person practitioners have variously interpreted the meaning to be given to the word "available" in the regulations. To be of avail a practitioner must be of value, use, service, or advantage to the person in such an emergency, and therefore it seems to me the term can be only in relation to the insured person and not to the practitioner, and that therefore it is of no moment or importance to contend that a practitioner was "available" because he was in the house and not sent for if the "emergency" exists. This is the only humane and honourable view, and, I think I may add, its practicable exposition. A definite adoption of this view at the next conference might save much discussion at medical service subcommittees and correspondence with practitioners.—I am, etc.,

Herriway, April 17th.

A. G. NEWELL, M.D.

Dental Treatment by Insurance Practitioners.

SIR,—In reference to the circular letter issued by the Ministry of Health to Panel Committees the following words occur in Anaesthetists' Fees, paragraph (b): "where teeth are extracted by an insurance practitioner as part of his agreement," etc.

May I ask if it is put of a doctor's agreement in rural areas to extract teeth for insured patients? If so, then I take it that the capitation fee covers the dental treatment provided, and that no charge should be made. May I ask also if it is permissible to refuse to give the treatment conditionally or unconditionally?

Two issues arise: First, ought the capitation fee to include the patient's right to dental extraction by his panel doctor? Secondly, is this an unconditional right? If the answer to these two questions is in the affirmative, then the Ministry of Health is lending encouragement to dental treatment by persons unqualified in dental surgery.—I am, etc.,

Pen-y-rhyn, Llanfair, Cornwall, April 17th.

J. C. JONES.

LOCAL MEDICAL AND PANEL COMMITTEES.

LONDON.

Post Graduate Courses.

THE London Panel Committee proposes to arrange for further courses of post-graduate lectures and teaching on similar lines to those followed in the courses held in previous years. The subjects proposed are at present clinical pathology and the diagnosis, treatment and prevention of venereal diseases. If a sufficient number express the desire, the Committee will endeavour to arrange for courses in general medicine and general surgery with opportunities for clinical teaching. The courses in clinical pathology, general medicine and general surgery will be held at Charing Cross Hospital; that in venereal disease at St. Thomas's Hospital. The fee for each course is £3 3s., which must be paid to the Secretary of the Panel Committee before a card of admission to the lectures is issued. In order that arrangements may be made for a start in the first week in May, applications must reach the Secretary, Staple House, 51, Chancery Lane, W.C.2, not later than April 18th. The Panel Committee is in negotiation also with the Metropolitan Asylum Board, with a view to the institution of post-graduate clinical demonstrations by the medical officers of the Board in the wards of the fever hospitals. The scheme provides that each course shall comprise a series of four or five clinical demonstrations in the wards of the hospitals, and that the fee for each course shall be one guinea, payable in advance to the Secretary of the Committee. Practitioners desirous of participating in these courses should make early application.

Chemists' Hours of Service.

Complaints have been made by practitioners in some districts that the insured persons on their lists have experienced difficulty in obtaining their medicines owing to the early

closing of chemists' shops. It is desired that concrete examples of such difficulties may be sent to the Secretary of the Panel Committee. The list of hours of service for chemists appears at the end of each *Borough Medical List*, a copy of which has been supplied by the London Insurance Committee to each practitioner on the panel.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced by the Admiralty: Surgeon Commanders A. C. W. Newport, M.V.O., S. Roach, and G. D. Bateman to the *Pembroke*, additional (temporary); W. T. Haydon to R.N. Barracks, Devonport; R. W. Stanistreet to the *Orion*. Surgeon Lieutenant Commanders H. StC. Colson and G. A. S. Hamilton to the *Pembroke*, additional (temporary); J. D. Bangay, O.B.E., to the *Victory*, for R.M. Division Portsmouth. Surgeon Lieutenants H. L. Pridham and J. W. Tighe to the *Pembroke*, additional (temporary); C. N. Ratcliffe to the *Bryony*, A. G. Taylor to the *Sandhurst*, A. W. Gunn to the *Impregnable*.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Temporary Captain M. Bates, O.B.E., relinquishes the acting rank of Major, October 15th, 1919 (substituted for notification in the *London Gazette*, April 22nd, 1920).

Captain C. B. Hogg is placed on the half-pay list on account of ill health.

The following temporary Captains relinquish their commissions, and retain the rank of Captain: C. H. Evans, W. B. Wilson, B. A. Chandle, W. L. Young, R. S. Dollard, J. G. M. Sloane.

Lieutenant (temporary Captain) M. F. D. Graham resigns his commission, and is granted the rank of Captain.

ROYAL AIR FORCE. MEDICAL BRANCH.

The following are granted short service commissions as Flight Lieutenants, with effect from, and with seniority of, April 4th: M. J. Caballane, O. St. L. Campion, S. E. Elphick, A. E. Jenkins, W. B. Wilson.

INDIAN MEDICAL SERVICE.

The promotion of Major A. Cameron, O.B.E., M.B., to his present rank has been antedated from October 15th to September 1st, 1915.

The promotion of Major R. S. Townsend, M.C., M.B., to his present rank has been antedated from February 1st, 1920, to August 1st, 1919.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

The following Captains relinquish their commissions and retain the rank of Captain: H. Smith, G. Day.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Major J. Owen, T.D., resigns his commission and retains the rank of Major, with permission to wear the prescribed uniform.

Major (acting Lieut.-Colonel) L. C. V. Hardwicke relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Captain H. W. Symons to be Major.
To be Captains: Major T. P. Cole (late R.A.M.C.), with precedence as from April 10th, 1918, and relinquishes the rank of Major; Captain H. V. Walsh (late R.A.M.C.), with precedence as from December 15th, 1918; Captain A. W. A. Davies (late R.A.M.C., S.R.), with precedence as from November 24th, 1917; Captain W. H. Kerr (late R.A.M.C., S.R.), with precedence as from May 1st, 1918; Captain A. E. Chisholm (late R.A.M.C.), with precedence as from March 11th, 1918; Lieut. C. G. Teall.

2nd *London Sanitary Company*.—Captain R. O. Sibley resigns his commission, and is granted the rank of Major.

TERRITORIAL FORCE RESERVE.

ROYAL ARMY MEDICAL CORPS.

Major G. F. Whyte, T.D., from General List to be Lieutenant-Colonel.

DIARY OF SOCIETIES AND LECTURES.

HUNTERIAN SOCIETY, *Sion College*, the Embankment, E.C.—Wed., 8.45 p.m., Annual General Meeting.

ROYAL COLLEGE OF SURGEONS, *Lincoln's Inn Fields*, W.C.—Museum Demonstrations: Mon., 5 p.m., Professor Shattock: Osteoma. Fri., 5 p.m., Professor Keith: Peritoneal Adhesions and Intestinal Stasis.

ROYAL SOCIETY OF MEDICINE.—Special General Meeting of Fellows, Mon., 5 p.m., *Section of Odontology*: Mon., 8 p.m., Mr. G. G. Campion and Mr. John Millard: Growth of the Face. *Section of Medicine*: Clinical Meeting at St. Bartholomew's Hospital, Tues. Tea at 4 p.m. Dr. G. Graham: Treatment of Diabetes. Dr. A. E.

Gow: Intravenous Protein Therapy. Dr. Drysdale: Splenectomy in Acholic Jaundice. Dr. F. R. Fraser: Digitalis Treatment by the Rapid Method. *Section of Urology*: Thurs. At St. Bartholomew's Hospital, 3.30. Operations by Mr. W. Gillingham. At 1, Wimpole Street, 8.15 p.m., Specimens: 8.30 p.m., Mr. R. Thomson: Treatment of Epispadias and of Extroversion of Bladder.

POST-GRADUATE COURSES AND LECTURES.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION, *Royal Infirmary*, Wed., 4.15 p.m., Dr. Katharine Chapman: X Rays in Diagnosis and Treatment.

LONDON HOSPITAL MEDICAL COLLEGE, Mon., 5 p.m., Dr. W. M. Feldman: Ante-natal and Post-natal Child Physiology.

LONDON LOCK HOSPITALS.—Clinics daily. *Lectures*: (at 91, Dean Street, W.), Mon., 2.30 p.m., Mr. Thomson: Preparation of Detoxicated Vaccines for Gonorrhoea; 5 p.m., Mr. Gibbs: Complications in Treatment of Syphilis; Tues., 2.30 p.m., Mr. McDonagh: Metallic Intoxication; 5 p.m., Mr. Juler: Syphilitic Diseases of Fundus, Orbit, and Ocular Muscles; Wed., 4.30 p.m., Mr. Joly: Chronic Gonorrhoea in the Male; Fri., 2.30 p.m., Demonstration of Tests used in Syphilis; 4 p.m., Mr. Abraham: Late Sequelae of Gonorrhoea in the Female. (At 233, Harrow Road, W.), Wed., 3 p.m., Mr. Ernest Lane: Venereal Disease in Women and Children.

MANCHESTER ROYAL INFIRMARY, Tues., 4.30 p.m., Dr. J. G. Clegg: Iritis and Cyclitis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—*Special Intensive Course*: Daily, 10.30 a.m. and 11.45 a.m. Demonstrations on Clinical and Laboratory Methods; 2 p.m. and 3 p.m., Groups of Illustrative Cases; 4.30 p.m., Clinical Lectures, free to medical practitioners. First Lecture, Monday, 4.30 p.m., Sir William Helle-White on Pleurisy. Full syllabus of Course printed in *Bulletin of Fellowship of Medicine*.

ST. JOHN'S HOSPITAL, 49, Leicester Square, W.C.—*Chesterfield Lecture*, Thurs., 6 p.m., by Dr. W. K. Knowles Sibley: Lupus Vulgaris and Erythematosis.

WEST LONDON POST GRADUATE COLLEGE, Hammersmith, W.—Daily, 10 a.m. (and Mon., Tues., and Fri., at 2.30 p.m.), Ward Visits; 2 p.m., In- and Out-patient Clinics and Operations.

APPOINTMENTS.

HAIN, Norman, M.B., Ch.M. Syd., one of the Honorary Physicians of the Saffron Hill Maternity Centre (Holborn, Finsbury, and City Border).

PUSCH, A. L., M.B., B.S. Lond., M.R.C.P., (Physician in

charge of Out-patients), Great Northern Central Hospital, Holloway.

STONKS, C. S., M.D. Camb., Certifying Factory Surgeon for the Colne (Lancs) district.

WALSHE, F. M. R., M.D., F.R.C.P., Assistant Physician to Out-patients, National Hospital for the Paralysed and Epileptic, Queen Square, W.C.

EDINBURGH ROYAL INFIRMARY.—*Resident House-Physicians*: H. A. Macmillan, M.C., M.B., Ch.B., to Dr. Fleming; A. Y. Cochran, M.B., Ch.B., to Dr. E. Bramwell. *Resident House-Surgeons*: R. M. Galloway, M.B., Ch.B., to Prof. Alexis Thomson; E. M. Byres, M.B., Ch.B., to Surgical Out-patient Department. *Clinical Assistants*: E. M. Carfoot, M.D., J. E. C. Henderson, M.D., and D. Watson, M.B., Ch.B., to Dr. Logan Turner.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS.

PINKERTON.—On April 19th, at a nursing home in Bolingbroke Grove, S.W., to Norah Dorothy Pinkerton, B.Sc., M.B., B.S., M.R.C.S., and John McLean Pinkerton, M.C., B.Sc., M.B., Ch.B., a daughter.

WOODWARD.—On April 11th, at 4, Harley Street, W., to Hilda Rose Robinson, wife of A. S. Woodward, C.M.G., Ch.B., M.D., F.R.C.P., a son.

MARRIAGE.

CAIRN-SARKIES.—On April 15th at Paddington, Myles Denton Cairn, M.D., B.Sc. Lond., of Hove, Sussex, to Mavis, younger daughter of Mr. J. Sarkies, late I.C.S. and Mrs. Sarkies.

DEATHS.

TYTLER.—On April 9th, at 25, Broadway, Withington, Manchester, Peter Tytler, M.D., aged 71, the beloved husband of Emily Tytler.

WRIGHT.—On April 2nd, suddenly, Joseph Farrall Wright, M.R.C.S., L.R.C.P., of 46, Derby Street, Bolton.

mucous membrane, an action which it shared with ammonia, for instance, in stimulating salts. This action accounted for the great preference which people had for brandy over other forms of alcohol, and old brandy in particular. He believed, however, that there was room for a systematic investigation into the action of alcohol in abnormal conditions in which the heart was weak and the blood pressure low, in order to settle the question whether there was any thing, after all, in the claim that alcohol had a stimulant action on the circulation. The experiments which seemed to negative a stimulant action on the heart and respiration had been carried out on normal animals and man, and the possibility remained that it might have some stimulant action on functions abnormally depressed, which those experiments had missed altogether. If such an effect existed, there was at present no evidence to warrant them in assuming its existence. As for the value of alcohol in promoting digestion, while there was experimental evidence that alcohol would cause a rather profuse outburst of gastric juice, the juice in question was not the normal juice, but a fluid low in acidity, and very poor in gastric ferment. Any effect which alcohol might have in promoting digestion must be due to its action in relieving anxiety or the effects of pain or fatigue.

Dr. Dale concluded by deprecating two attitudes towards the therapeutic use of alcohol: one, that alcohol was a mysterious fortifying substance which would build up the constitution, and could be prescribed without danger and with probable advantage, the other that because it was a dangerous thing for the public to use, its rational use in medicine was to be avoided.

Dr. O. LEXON described some experiences with alcohol in the early stages of the starvation treatment of diabetes. It appeared that, after some period of semi starvation, patients managed to adapt themselves to the limited diet, even though alcohol was not continued, either the body acclimatized itself to the small supply of food, or else the patients learned to utilize cellulose. He had not sufficient evidence to show that it was necessary for alcohol to be continued indefinitely in this treatment of diabetics. He believed with Dr. Dale that the only way in which alcohol could improve digestion was by altering the state of mind, not by any direct action on the stomach.

Dr. ROBERT ARMSTRONG JOYCE said that he had found alcohol to have a definite hypnotic effect in some cases of acute mania, and in that condition it was eliminated from the skin better and more quickly than in melancholia. In juvenile melancholia and senile depression the prescription of alcohol was inadmissible. He had had 330 cases of general paralysis of the insane under his care while resident at Claybury, and he had seen a number of private cases, and he had to record no good effect from the administration of alcohol. In cases of acute delirious mania, puerperal insanity with rapid exhaustion, the free administration of alcohol was often the only thing that would save life. He had tried various stimulating diets, but dry wine in the shape of dry sherry or moselle had saved lives when nothing else had availed.

Professor KILSON said that experimental evidence proved that when the respiratory centre was depressed the effect of alcohol was to depress it still further. Alcohol was not a stimulant to respiratory action, unless reflexly from the mouth.

Mr. ARTHUR EVANS said that during the last two years at the London Temperance Hospital he had done 254 operations, with 12 deaths. The deaths were practically inevitable from the nature of the cases. Alcohol was given in no instance. He claimed that the statistics of 44,000 patients admitted since the foundation of the hospital—to only 135 of whom, mostly cases of pneumonia, was alcohol given—compared well with those of other institutions.

Mr. A. PLATZ GOULD, from the chair, in closing the discussion, remarked that the withholding of alcohol in the cancer wards of the Middlesex Hospital and the administration of morphine with a much more sparing hand than formerly had added greatly to the patients' comfort.

A NEW medical faculty has recently been established at Recife, in the government of Pernambuco, so that there are now seven medical faculties in Brazil. As the country possesses 35,000,000 inhabitants, this number of medical schools is considered to be hardly sufficient.

THERAPEUTICS OF RADIUM.

ANNUAL REPORT OF THE LONDON RADIUM INSTITUTE.

THE annual report of the London Radium Institute for 1920 is constructed on a different plan from its predecessors. The details of cases are confined to a table, and Mr. Maynard Pinch, F.R.C.S., who has been its medical superintendent since the Institute was founded ten years ago, devotes the body of the report, which fills nearly thirty pages, to a discussion of general questions which will be of direct value to others who are doing clinical work with radium or desire to form their own opinion of its value.

After a short account of the physics of radium rays he discusses their action on normal tissues, and from a brief review of the pathology of the diseases treated passes to a consideration of the reasons which should determine the selection of the class of irradiation to be employed and the length of exposure to be given to produce a destructive or stimulant effect, as may be necessary. A statement as to the absorption of beta and gamma rays prepares the way for particulars of the screening to be used to obtain rays of different qualities. The screens used for therapeutic purposes are of a thickness which do not absorb more than a small percentage of the gamma rays, but stop a percentage of the beta rays ranging from practically all to only 37 per cent.

In practice the use of radium is governed by the knowledge that has been acquired as to the action of the several sorts of rays on the elements of healthy tissues and of diseased structures. The alpha rays are particulate, travel relatively slowly, and are so little penetrating as to possess no therapeutic value. The beta rays, negative electrons travelling with a velocity of the order of that of light, are of the type of x-rays and, like them, present a considerable range of penetration, so as to be divisible into "soft" beta rays, stopped by 0.2 mm of aluminium; "medium," which pass through this thickness of aluminium but are stopped by 0.2 mm of silver, and "hard," which pass through this thickness of silver. The gamma rays of the same type as the most penetrating or hardest x-rays, are only slightly diminished by the most absorptive screens used for therapeutic purposes, they easily penetrate the skin and reach the internal organ. The beta rays do not penetrate far, the hard being reduced to about 6 per cent. by 1 cm of body tissue. Beta rays unscreened are used in the treatment of epitheliomata which tend to fungate and not to invade the tissues, for those that so tend the soft rays are cut out and medium and hard rays only used.

As a general principle it may be assumed that radium rays stimulate growing cells, the effect being the greater the more rapidly the cell is growing, until stimulus is replaced by destruction in lympho sarcoma the destruction may be so rapid that the patient suffers from well marked symptoms of toxæmia with rise of temperature to 101° to 102°. On the other hand, cells of fibrous tissue may be just sufficiently stimulated to form bands or tracts of such tissue, and in this way continuance or spread of the malignant cellular growth may be hindered. Growths of mesoblastic origin are more susceptible than those of hypoblastic or epiblastic origin, between the two last named certain differences are to be observed, the former being more readily influenced by short exposures to large quantities of radium salts, the latter by long exposures to small amounts.

The Skin.

The effects produced in some normal tissues and organs by exposure to beta and gamma rays are reviewed. In the skin the first effects are proliferation and then enfoldment of the epidermis, congestion of the dermis with degeneration of hair follicles and sebaceous glands, multiplication of the connective tissue cells, forming a plexus which almost obliterates the normal fibrous and elastic tissue, and proliferation of the lining cells of the blood vessels (embryonic regression). Eventually the fibroblasts become arranged in parallel layers containing a relatively large number of elastic fibres so that the scar is soft and supple. Regeneration of the hair follicles and sebaceous glands takes place also. The proliferation of the cells of the blood vessels is followed, if the radiation be prolonged and intense by degeneration and leucocytic infiltration. Milder radiation for short periods at long intervals, leads to fibrosis of the walls, it is in this way that the cure of angiomata is induced.

The Blood.

Periodical examinations have been made of the blood of nurses and laboratory workers at the Radium Institute, who are subject to frequent short exposures to the gamma radiation. Dr. J. C. Mottram, Director of the Research Department, has observed at first a slight diminution in the number of red cells, accompanied by a rise in the colour index. If exposure to radium continues, the increase is succeeded by a decrease both in the number of red cells and in the haemoglobin until both have fallen to 50 per cent. or lower. The more important effect is on the white cells. Leucopenia invariably occurs; the white cells, Mr. Pinch states, are frequently reduced to half the normal proportion, the reduction falling chiefly on the polynuclear leucocytes and the lymphocytes. The effect is slowly produced, but is very persistent, and it may be many months after complete withdrawal from radium work before the percentage again becomes normal. In a paper published last December,¹ Dr. Mottram described three deaths among radium workers, two in England and one in France; in all three aplastic pernicious anaemia was present and in two death was ascribed to this condition; in the third there were signs also of infective endocarditis.

The association of mild anaemia of the pernicious type as above mentioned with these three cases of profound aplastic pernicious anaemia led to the conclusion that the important etiological factor was exposure to radium and indicates a direct action of the gamma rays on the bone marrow. This suggestion was tested by exposing rats to varying amounts of gamma radiation; when their bone marrow was compared with that of normal animals the number of mitoses in the radiated animals was found to be smaller, indicating a decreased output of blood cells. During 1920 the workers at the Institute were better protected, and by February, 1921, the blood condition had reverted to the normal.

Radium rays quickly produce a profound effect on the spleen; the connective tissue increases, the cellular elements diminish, and there is an almost complete disappearance of lymphocytes; concurrently the proportion of polynuclear and large mononuclear cells in the blood is greatly decreased, and there is an accumulation of red corpuscles in the bone marrow and many small haemorrhages into its substance.

Dosage.

Mr. Pinch devotes rather more than half of the space his report occupies to consideration of the mode of applying radium in the treatment of various forms of disease in which the method has proved of value. The question of dosage is, of course, of very great importance; for, if the dose be too weak, the pathological cells, instead of being checked or destroyed, may be stimulated to increased activity, whereas if the dose be excessive, destruction not only of the morbid, but also of the normal cells occurs, resulting in great loss of tissue and the formation of an intractable ulcer or fistula. For full details the report itself must be consulted; we can only summarize the recommendations and indicate their general nature.

Reference has already been made to the treatment of epitheliomata, but it may be added that tubular epitheliomata characterized by long, finger-like columns of cells running at right angles to the skin surfaces and permeating the subcutaneous tissues should, it is advised, be treated almost entirely by gamma radiation. Since 94 per cent. of the beta radiation is absorbed by one centimetre of tissue, and these growths often extend much more deeply. Cross-fire radiation—the apparatus being so applied that the focus of their combined radiation corresponds with the centre of the growth—should be adopted. The exposure should be prolonged in a series for twenty-four to thirty hours, and the series repeated at intervals of not less than four weeks. A screen of two millimetres of lead, which cuts off practically all the beta rays, should be used.

Spheroidal-celled carcinomata, the most common and typical form being cancer of the breast, may be beneficially affected, especially in spare women who have passed the menopause. If such a patient, possessing a fair inherent power of resistance, the growth in its earliest stage shows on microscopical section all transitions from a dense central scirrhotic focus to a comparatively medullary condition at the periphery. In the former there are but few cells and

much connective tissue; in the latter connective tissue fibres are scanty and malignant cells predominate. The object of treatment by radium is to reinforce Nature's attempt at the arrest of the disease. Prolonged gamma radiation diminishes the vitality and arrests the proliferation of the malignant cells, but stimulates the multiplication of the fibroblasts. It is not sufficient to radiate the primary growth, equal attention must be paid to the surrounding lymphatic areas.

Columnar-celled carcinomata, the most common site for which is the intestinal canal, are difficult to treat with radium, both on mechanical grounds and because they originate in a mucous membrane with a submucosa abundantly provided with lymphatics, so that infiltration speedily occurs. Gamma radiations from screened applicators have been used for carcinoma of the stomach, small intestines, and colon, but little real benefit has been observed. In the rectum, however, direct application is possible; if the tumour be small and exuberant a screened emanation tube may be inserted into its substance. If the growth be annular, the introduction within the lumen of a powerful tube of 150 or 200 mg., screened with 2 mm. of lead, for eighteen hours may diminish the rate of growth and lead to healing of the ulceration, lessen the existing circumjacent infiltration, and render the condition operable.

Sarcomata are best treated by gamma irradiation; large quantities of radium should be used and the applicators disposed so as to secure equal intensity of radiation in all parts of the growth; often this is best accomplished by burying one or more radium tubes, screened with 1 mm. of silver, in the centre of the mass. Powerful applicators, screened with 2 mm. of lead, should be applied over and around its circumference. The reaction that may be produced owing to the rapid destruction of the sarcomatous cells has already been mentioned.

In *melanoma* (melanotic sarcoma), which is believed to arise from the pigment cells of the corium, and to be, therefore, of epiblastic rather than mesoblastic origin, beta rays may be used to produce an intensely destructive reaction. In such cases the lymph channels leading from the primary focus should at the same time receive prolonged gamma radiation, in order to destroy any foci that may be present.

Rodent ulcer is, for clinical purposes, recognized to occur in two forms: in the first, of a hypertrophic and exuberant type, with slight superficial ulceration and a distinct rolled edge, the prognosis is good. Unscreened apparatus emitting beta rays is used for one to three hours, according to the density of the lesion. The rolled edge is evidence of a considerable degree of resistance to the disease, and the irradiation recommended produces degenerative necrosis of all the malignant tissue and possibly of a small layer of the normal tissue. The stimulant action of the gamma rays induces rapid multiplication of the fibroblasts, and the resulting scar, though slowly produced, is smooth, soft, and supple. Growths of the excavating type, with thin overhanging edges and a soft gelatinous base, form the second class. The absence of a rolled edge shows that the defensive powers are deficient and the prognosis is not so good. A smaller dose must be used, and it must extend beyond the visible margin in order to deal with outlying invasive columns of cells. Recurrence is, however, very frequent. In long-standing cases, with great destruction of the tissue and invasion of the mucous, cartilaginous or bony tissues, the beta rays should be cut off. Radium irradiation of any kind is powerless to cure rodent ulcer of bony tissues, and has little influence on that of cartilage. Affected portions of these tissues should, therefore, be removed before radium treatment is begun. Gamma irradiation applied to the borders of the growth and its deeper processes will often arrest the progress of the disease, diminish the pain, and induce some slight degree of repair.

Endotheliomata, met with most commonly in connexion with the parotid gland, but sometimes observed in the submaxillary gland and carotid body, can often be usefully treated by gamma rays. If the growth be inoperable it should be treated by cross-fire, using heavily screened external applicators emitting gamma rays only, supplemented by the insertion of a radium tube screened with 1 mm. of silver into the centre of the growth for twenty to thirty hours.

In *uterine fibro-myomata* radiation may be used when

¹ Archives of Radiology and Electrotherapeutics.

the patient objects to surgical operation. When haemorrhage is the principal symptom relief may confidently be anticipated from the introduction of a 100 mg. tube, screened with 2 mm. of lead and rubber, into the uterine cavity, supported by a plate of equal strength, screened in a similar fashion and applied externally over the fundus. Exposure of twenty-four hours should be given, to be repeated, if necessary, after three months. The treatment causes exfoliation of the hypertrophied and congested uterine mucous membrane, which is afterwards replaced by healthy cells, together with proliferation of the endothelial cells of the enlarged uterine blood vessels and perivascular fibrosis, leading eventually to endarteritis obliterans. Treatment cannot be counted upon to diminish the size of the tumour unless it be of the soft myomatous vascular type. In a patient nearing the climacteric it may be proper, with her consent, to attempt to produce premature menopause by supplementing irradiation of the uterine cavity by prolonged irradiation of both ovaries with powerful screened applicators.

Spleno-medullary leucocythæmia in the early stage may be greatly benefited by gamma rays, using flat applicators containing from 200 to 500 mg. screened with 2 mm. of lead, for twenty to thirty hours. This is usually followed by a reduction of 50 per cent. or more in the white blood cells and a decrease in the size of the spleen. If extensive fibrosis of the interstitial tissue of the spleen has already taken place, as may happen after much treatment with rays, no great decrease in the size of the organ can be expected, but the number of white blood cells may be considerably reduced. The treatment may have to be repeated in two or three months.

Lymphatic leucocythæmia is often benefited by irradiation with gamma rays for periods of from twenty to thirty hours. A decrease in the number and percentage proportion of the leucocytes occurs, and may persist for two months or more, but the ultimate prognosis is bad.

Exophthalmic goitre may be materially benefited by exposures to about 200 mg. of radium, screened with 2 mm. of lead, for a total period of twenty-four to thirty hours; temporary exacerbation follows, but is succeeded by improvement associated with fibrosis of the connective tissue of the thyroid.

Tubercle bacilli in cultures are not killed by an exposure of less than at least 100 hours to radium rays, but shorter radiation is believed to diminish their vitality, and it is thought that the beneficial effect observed in lupus is brought about in this way. If ulceration has not occurred, applicators screened with one-tenth of a millimetre of lead, which cuts off three-fourths of the beta rays, may be used for two or three hours, and repeated at intervals of about six weeks; no breach in the skin is produced, the congestion and induration are much lessened, and after repeated exposures the skin becomes apparently normal. If the patch of lupus is ulcerated but superficial, with little accompanying induration, an unscreened exposure of an hour or an hour and a half, utilizing practically all the beta rays, produces a destructive reaction of moderate degree, which is followed by the formation of a smooth and supple scar. In lupus of long standing with extensive ulceration and destruction, screening with 2 mm. of lead, yielding the gamma rays only, for a total exposure of twenty to thirty hours is preferable. In tuberculous adenitis cross-fire irradiation may be of use if cessation has not taken place.

In *capillary naevi*, whether "spider" naevi or port wine stain, screening with 0.1 mm. of lead, which allows the hard beta rays as well as the gamma rays to pass, should be used to produce proliferation of the endothelial lining of the vessels; their slow constriction follows the gradual development of fibrous tissue from newly formed fibroblasts. The treatment of cavernous naevi by radium is commonly very successful, and should be undertaken as early as possible, even in infancy.

CHEMICO-PHYSICAL LABORATORY.

Mr. W. L. S. Alton, F.I.C., Director of the Chémico-Physical Laboratory of the Institute, gives an account of the method in use for separating radium emanation in a condensed form for therapeutic purposes.

Dr. Mottram reports that the Medical Research Council has lent 220 mg. of radium to the Research Department,

ROYAL MEDICAL BENEVOLENT FUND.

ANNUAL MEETING.

The annual meeting of the Royal Medical Benevolent Fund was held on April 5th, when Sir Thomas Barlow, Bt., President, was in the chair.

The annual report showed an increase of £530 in donations and subscriptions over the previous year, while the amount distributed in grants and gifts was £4,021, as against £3,897 in 1920. Attention is called to the fact that the annual grants which the committee can allocate depend upon the amount of donations and subscriptions received, and all friends of the Fund are urged to make its wants more widely known, preferably by personal canvass. Owing to the diminished purchasing power of money, it is essential that the average grants should be considerably increased. The annuitants numbered 178.

The War Emergency Fund had made grants amounting to £5,926, and had thus rendered invaluable assistance to a large number of medical practitioners who on demobilization had found themselves on return to practice unable to carry on without such help. The committee had already agreed to bear the cost of the education of twenty-five boys and girls at public schools, and they would welcome applications for such purpose on behalf of any who are eligible for help from the fund. The total sum received for the fund was £34,818, and the amount expended was £18,920.

The committee express their thanks to the editors of the *BRITISH MEDICAL JOURNAL* and the *Lancet* for their great assistance in publishing reports, and to the Medical Insurance Agency for its gift of £375 towards the general expenses.

The following officers were re-elected: *President*, Sir Thomas Barlow, Bt.; *Treasurer*, Sir Charters Symonds; *Honorary Secretary*, Dr. Newton Pitt.

COMMITTEE MEETING.

At the meeting of the Committee held on April 12th twenty-nine cases were considered, and £397 voted to twenty-six applicants. The following is a summary of some of the cases relieved:

Widow, aged 67, of M.D.D.B. who died in 1913. Applicant was left entirely without means. She has five grown-up children, but none of them are able to help her. Since the death of her husband and she has paid rent—15s. a week—by selling her furniture. Two sisters, now dead, used to clothe and help to support her. Voted £12 in two instalments.

Widow, aged 61, of M.R.C.S.Eng. who died in 1915. Applicant asks help from the Fund owing to the death of her husband, who was her chief support. Son only receives 9s. a week. Voted £10.

Widow, aged 67, of L.F.P.S. Glas. who died February, 1921. Applicant's husband was granted £10 in the last year on the Fund. Applicant is now left with £10 a week. Voted £12 in two instalments.

Daughter, aged 51, of M.D.D.B. who died in 1913. Owing to ill health and an operation in November last she is now incapacitated and is dependent upon her sister who earns her living as a dressmaker. Applicant is entirely without means. Voted £18 in two instalments.

Daughter, aged 52, of M.R.C.S.Eng. who died in 1922. Applicant worked for nineteen years as a church worker in Wales, but owing to partial blindness and ill health has had to give it up. The Royal United Beneficent Association allows her £25 per annum. She also receives a little help from the Guild and a grant from the Fund for the last ten years. Relieved ten times, £135. Voted £18 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S., at 22, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

A CERTAIN amount of confusion exists with regard to the date of the first use of ether for producing surgical anaesthesia. Dr. W. W. Keen was made recently to say that it was first employed for this purpose on September 30th, 1846. The story was correctly reported in the *BRITISH MEDICAL JOURNAL* of October 17th, 1895. On the date mentioned Dr. T. G. Morton, a dentist, used it with complete success for the extraction of a tooth. Ether was first used for a surgical operation on October 16th, 1846, when Morton gave ether for Dr. John C. Warren in the Massachusetts General Hospital; the operation was for a congenital vascular tumour of the neck.

British Medical Journal.

SATURDAY, APRIL 23RD, 1921.

AURICULAR FIBRILLATION AND FLUTTER.

In the Oliver-Sharpey lectures, of which the report is completed in this issue, Dr. Thomas Lewis has described an attempt to ascertain the nature of certain grave disturbances of the human heart beat. The attempt has succeeded, and the solution is presented in the lucid manner characteristic of the lecturer. After years of patient investigation, aided by able and painstaking assistants, he is now confident that he has at last solved the riddle of the disorderly action of auricular fibrillation and the rapid and varying ventricular rate in auricular flutter. That this is of very great practical importance is obvious in view of the fact that auricular fibrillation is the most common cause and frequently the immediate cause of cardiac failure.

Fibrillation of the auricle was first recognized as a clinical entity by Sir James Mackenzie in 1890. It was he who appreciated the specific nature of its disorderly action and how it differed from the other arrhythmias, but he was not then in a position to state the essential nature of the happenings in the auricles. At first he was inclined to the view that the auricles were simply distended and paralysed. Later he held that the auricles and ventricles contracted simultaneously in response to an irregular stimulation originating in the auriculo-ventricular node; the term nodal rhythm was employed to indicate this form of arrhythmia. This view in turn had to be abandoned when, in 1910, it was demonstrated by means of the electrocardiograph that the state of the auricles in these patients was identical with a condition produced experimentally even so far back as 1887, and termed auricular fibrillation. In Dr. Lewis's two lectures we have the final explanation of this important cardiac disorder.

Normally, the contraction of the auricles is a co-ordinated movement, occurring regularly. The stimulus originates in the sino-auricular node or pacemaker, and initiates a response in the auricles. Dr. Lewis shows that the action of the auricles is fundamentally different when flutter and when fibrillation occurs. The normal pacemaker is side-tracked, and a peculiar "circus movement" begins. In this movement the wave of contraction travels in a circular path, and constantly passes over the same ground. In order to form a clear conception of this mode of auricular activity it is essential to remember that, following every contraction of the auricular wall, the myocardium becomes refractory. This refractory stage persists for a varying time, and when it finally passes off the fibres are sensitive and responsive. When circus movement is present a wave of contraction is continuously circulating. The crest of this wave is always chasing its own wake across a gap of responsive tissue, and so long as there is this area of responsive muscle fibre in front of the advancing wave it continues to progress. It is obvious that this gap, both in its extent and also in the degree to which it has recovered its responsiveness, is of extreme importance. As Dr. Lewis indicates, if that gap could be closed, the circulating wave would come to an

abrupt termination and permit the normal pacemaker to resume control of the heart.

Auricular flutter and fibrillation are both shown to be due to the same type of abnormal contraction of the auricles—namely, circus movement. There are, however, certain important differences in the action of the auricles in these two conditions. In fibrillation the rate is about 50 per cent. higher than in flutter, and the action is not regular.

The explanation of these differences is the most fascinating section of the lectures. It is shown that the higher rate in fibrillation is due to the fact that the path of the circulating wave is shorter than in flutter. In many cases of flutter the "mother wave" encircles both venae cavae, while in fibrillation the ring of muscle fibres around the opening of the superior vena cava alone may be involved.

The reason for the irregular action in fibrillation is to be found in the condition of the responsive gap already mentioned. With the very rapid rates of contraction in flutter and fibrillation there is a decrease in the duration and quality of the responsive phase, and a condition of partial refractoriness develops; this interferes with the progress of the advancing wave of contraction. In fibrillation this barrier becomes pronounced, and the rate of the onward movement of the wave varies, producing the disorderly rhythm of the ventricles so characteristic of fibrillation of the auricle.

Prolongation of the refractory state produces a corresponding reduction of the gap. This indicates the lines along which further investigations must take place, and we may look forward to the time when we shall be in possession of remedies which, by increasing the refractory period and closing the gap, will break the vicious circle underlying both flutter and fibrillation. The foundations for such further investigations have been well and truly laid.

THE PREPARATION OF SCIENTIFIC PAPERS.

ONE of the crosses the medical journalist has to bear is the curious disregard of the literary amenities displayed by a large number of the members of the medical profession who send communications for publication. Perhaps the majority have now become aware that when writing for the printer only one side of the paper should be used; but many have not advanced to this stage. It is common for a surgeon to send in a bundle of sheets of paper of various sizes, fixed together with a safety-pin and containing, mixed up with the text, rough diagrams and bedside charts perhaps sprinkled with notes and defaced by blots and corrections. Such slovenliness is, of course, inexcusable. But writers who are prepared to take more trouble may still be guilty of the most unscientific lack of attention to details. To have a manuscript typewritten, and then to send it for publication without revision is a crime comparable to operating with unwashed hands; yet the Medical Research Council finds it necessary to insert a warning on this head among the "Notes upon the preparation of monographs and reports for publication" which it has recently issued. A comparable fault is failure to write proper names and technical terms legibly. It was said of Lord Brougham that he had three distinct handwritings—one that the majority of people could read, one that his clerk could read for a fee, and a third that had to be sent to the printer—and, undoubtedly, an experienced compositor acquires an extraordinary skill in deciphering careless writing. But he ought not to be put to the test; if the author's manuscript has been

typewritten and is uncorrected, or the correction is illegible, the skill and experience of the compositor is of no avail.

The next point made by the Medical Research Council is that footnotes as a general rule are not desirable; with this we agree; a footnote generally means that the author has not sufficiently digested his matter. It used to be a fashion with historians to print copious notes, and remonstrance was met by reference to the practice of Gibbon; but his notes, when more than references to his authorities, usually contained matter which he judged it becoming to veil in the decent obscurity of a dead language.

Another point is one to which we have several times called attention. "The decimal point," the Council says, "should never be placed at the beginning of a number, as when so placed it may well be overlooked by the compositor; for example, the form 0.5 should be used, not .5." Then, again, much trouble would be saved if authors would remember that "tables should be prepared on separate sheets and numbered consecutively in the order in which they are to be used in the text." Instructions to the printer as to where the tables may best be inserted should be given at the proper place in the text. Such instructions cannot always be carried out in the case either of tables or diagrams, owing to the size and shape of the page; therefore, when referring in the text to tables, the number of the table should be quoted, and such phrases as "the following table" avoided. Next, with regard to illustrations, diagrams, or charts, the Medical Research Council points out that they should never be drawn on the manuscript or typescript, for they have to be sent to the engravers. "Underlines," legends or descriptions, however, are sent to the printer, so that each drawing or diagram should be numbered. A drawing should be made in Indian ink on stout paper (Bristol board); in order to save time and diminish correspondence an underline bearing the same number should be attached to it or written on the back, and complete lists of all drawings, arranged in numerical order, with copies of the underlines should be appended to the manuscript or typescript. The Medical Research Council, while stating that it will, "of course, exercise its discretion as to the number and cost of illustrations," lays it down that their number should be reduced to the minimum necessary for the elucidation of the text, and that line drawings should be employed in preference to wash drawings or photographs, as the cost of line blocks is about half that of half-tone blocks, which, moreover, must usually be printed separately on special paper, multiplying the total cost by five or six. Coloured illustrations should be avoided, their cost is prohibitive in these times; yet we have known authors send in a chart in three colours, a chart which, in the case of the *BRITISH MEDICAL JOURNAL*, would probably have cost at least £100 to print, whereas the same effect and contrast could be obtained in black and white. Photographs are, as a rule, the least desirable methods of illustrating a scientific paper; from 15 to 25 per cent. of detail is inevitably lost in the process of reproduction, and the inclusion of inessential details in the background leads to confusion. Line drawings, as has been said, are far better; they should be drawn on a large scale, and can then be reduced during the process of reproduction to a convenient size; the author, however, must remember that any reference letters or numbers will be correspondingly reduced, and therefore should be drawn large. The author should not insert any words in ink on drawings, diagrams or charts; such indications should be put in very lightly in pencil,

allowing a skilled draughtsman to give them their final form.

The concluding section of the Notes deals with scientific names of animals and plants. These names, as is well known, are formed according to the binominal or Linnaean system; for the manner of their use international rules exist, and it is illiterate not to abide by them. The specific name must be written with a small initial letter; thus, *Bacillus typhosus*, not *Bacillus Typhosus*; further, "Specific names should not be employed alone, but should always be preceded by the full name or initial capital letter of the genus to which they belong; for example, write *Bacillus coli* or *B. coli*, not *coli*." This touches on the use of laboratory slang; it may be all very convenient in a laboratory, but it has no general sanction, and may easily be misunderstood by workers in another laboratory, or by those whose laboratory experience has been left some years in the past. In zoological nomenclature specific names should be written with a small initial letter, even when they are formed from names of persons or places—thus, we should write *Trypanosoma brucei*, not *Trypanosoma Brucei*. Unfortunately, the botanist uses an initial capital letter when the specific name is derived from that of a person; for example, he would say *Phlox Drummondii*, not *Phlox drummondii*. Since bacteria are included in the vegetable kingdom, the same convention might be applied to them, but the Medical Research Council expresses the opinion that the specific names of micro-organisms should be written with a small initial letter; for example, *B. welchii*, not *B. Welchii*. Finally, we would quote, since it can neither be improved nor abridged, the concluding paragraph of the Notes: "Generic names are frequently used as common English nouns denoting classes. In such cases the name should be written in roman and not italic type, without an initial capital; for example, 'large numbers of bacilli and amoebae were found in the specimen,' not '... of *Bacilli* and *Amoebae*...' (The latter statement would mean that many different species belonging to the genera *Bacillus* and *Amoeba* were found.)"

PERSISTENCE OF GASTRIC ULCERS AFTER PERFORATION.

It is very generally held that a gastric or duodenal ulcer which has perforated will after operation give rise to no further trouble. The common practice of simple suture of such a perforation is based on this belief. A minority is of the opinion that perforations of duodenal and gastric ulcers do better if a gastro-enterostomy is made at the same time. There can be no denial of the fact that the satisfactory infolding of a perforated ulcer, typically a small perforation in the centre of a relatively large indurated area, leads to a very definite deformity. The wonder is that so many cases should apparently suffer so little physiological upset and actual obstruction following the operation. A certain proportion—and just what that proportion is it would be interesting to know—do suffer from persistent dyspepsia after closure of their perforations. (Two out of Farr's¹ twenty-one patients who recovered after perforation came to gastro-enterostomy for pyloric stenosis.) Lewisohn² discusses this interesting question, and records four cases, seen within two years, in which re-operation became necessary owing to recurrence of symptoms. Of these, two were duodenal, one gastric, the site of the fourth not being ascertainable owing to adhesions. The absence of cure after perforation is well shown by another case, in which an ulcer that had perforated and been sutured gave way a second time,

¹ Farr, C.: *Ann. Surg.*, p. 591.

² Lewisohn, R.: *Ibid.*, November, 1920, 595.

necessitating immediate operation. It may be argued that these cases are rare, that the usual post-perforation course is generally much happier and more benign. Lewisohn believes that a gastro-enterostomy at the time of suture obviates these ill results, whilst not in any way reducing the percentage of recoveries. The author has carried out this practice in 8 cases without a death, and refers to Deaver's larger series (25 cases with one death). The surgeon will obviously have to use his judgement in selecting cases suitable for immediate gastro-enterostomy. In cases of perforation seen late, in large perforations with extensive peritoneal soiling, in cases in poor general condition, the old saying of "Quick in and quicker out" is the only possible advice. But in early perforations with limited extravasation of gastric and duodenal contents it will often be well to do a gastro-enterostomy as soon as the perforation has been satisfactorily closed and the ulcer buried. This method of treatment finds its happiest field of application with duodenal and juxta-pyloric ulcers. It is now recognized that ulcers of the stomach at a distance from the pylorus cannot be infallibly cured by gastro-enterostomy. Partial gastrectomy and pylorotomy are the operations of choice here. But he would be a bold man who would perform the last two operations upon patients with perforated ulcers. Such bold men do, however, exist, for Gauthier² has performed pylorotomy with posterior gastro-enterostomy and jejuno-jejunostomy on a man 56 years old suffering from a perforation, six hours old, of a callous ulcer of the stomach.

THE NEW SERIES OF THE "INDEX MEDICUS."

With the appearance of the first quarterly part of the first volume of its third series the *Index Medicus* breaks away from tradition in several respects. Instead of being a monthly *catalogue raisonné* of medical works (books, articles in journals, pamphlets, etc.) with an annual alphabetical index of its own contents, it becomes a quarterly alphabetical list without an annual index, each part being, so to say, its own index. This is the change stated generally, and it would seem, therefore, as if once more the alphabetical index has defeated the *catalogue raisonné*, and remains in possession of the field; but this is not completely so—traces of the subject-arranged system remain, at any rate, for a time. For instance, Dr. Fielding H. Garrison, one of the two editors, in order to orient the reader who is used to the older arrangement, gives a grouping of the various subject-rubrics under such headings as Anthropology, Bacteriology, Biology, Climatology, Dermatology, and so on. This list, which occupies the first two or three pages of the quarterly part, will, it would seem, appear at least for a while, until custom has familiarized the new plan of consultation. In this small alphabetically arranged *catalogue raisonné* there is a sort of rudimentary survival of the prevailing plan with which so many were familiar in the first and second series of the *Index Medicus*. Under "Hygiene," for example, in this small preliminary grouping, there are found the following headings, any one of which may be found in other parts in its alphabetical place: Abattoirs, air, dust, factory workers, flour, food, habitations, health insurance, heating, hygiene (industrial), hospitals, marriage, meat, etc. The editor has thus shown his real desire to prevent any serious jar in the change of gearing in his bibliographical automobile. Further, at the conclusion of each year (four parts), an alphabetically arranged index of authors is to be supplied. Three changes on the title-page accompany these internal rearrangements—the word "quarterly" takes the place of "monthly"—namely, *Index Medicus: A Quarterly Classified Record of the Current Medical Literature of the World*; a joint editor's name appears—namely, Albert Allemann, M.D.; and "third" is found instead of "second" series. Of the change in system J. W. B. sends us some comments

which may be summarized as follows: "The alphabetical system of arranging the subject-rubrics now adopted is not free from inconvenience. Closely related matters are separated sometimes by the whole length of the alphabet, and a remarkably active intelligence is necessary to exhaust all the possible headings under which a reference may reasonably be expected to appear. Then, again, comparatively unimportant subjects have the same largeness of type and amount of space allotted to them as many much more outstanding matters. Some rubrics are almost useless as they stand, such as *Girls (Defective)*, under which one finds a reference to a paper on 'Girl Guides and the Welfare of the Defective Girl'; the mysterious *Orbitopagus* has the same typographical rank assigned to it as, say, *Ointments*; and a paper on *Digestion* is not likely to be looked for under the rubric *Onions*. Every new drug that the chemist finds a name for and that the enthusiastic practitioner gives a trial to at once springs into prominence by the system adopted here. The fact is that modern medicine is a very difficult subject to index, and whilst the method now employed may do away with some of the inconveniences of the former plan, it will introduce others of a new kind. At the same time it makes for rapidity of consultation with perhaps a slight lessening of exhaustiveness in the result obtained; the balance is therefore, perhaps, rather in favour than against the change. There is one distinct advantage: the systems in use in the *Index Catalogue* and in the *Index Medicus* are thus unified. Of these two publications the latter is in a sense the more important, for it gives access to the most recent additions to that storehouse of medical literature. America, the Carnegie Institution of Washington, and the editors deserve well of all English-speaking peoples for providing guides so trustworthy to the literary contributions constantly being made in all lands to the art and science of medicine. To the medical teacher, to the research worker, to the writer of book or article, to the specialist, and to the practitioner who wishes to keep abreast of the times, the *Index Medicus* is the only absolutely complete *valde mecum* to the literature of his subject. By its means, and with access to a good medical library, he may at first hand consult the original papers on any matter which may be exercising his mind. It gives him the titles, and much may be learned even from a title." In this connexion it will not be without profit to quote what Dr. Garrison says about titles. He says, re-echoing a remark made by Dr. Fletcher, at one time editor of the second series, "there are titles which may be unassignable under a strict classification"; and he continues: "this is especially true of titles which have no true centre of gravity—for example, those in which two or more ideas are exploited with equal weight, or in which two or more disparate diseases are brought into causal or other relations, or in which the true intention is not apparent, even from the text of the book or article itself." Editors of medical periodicals know only too well such obscurely named articles, and not a few really important discoveries have been lost to view through such faults in terminology. Dr. Garrison closes his prefatorial notes with a sentence of good advice: "the simple rule of Billings (the first editor of the *Index Catalogue* and *Index*), 'Give the paper a proper title,' commends itself equally to medical authors, editors, and publishers."

THE COCKROACH.

THE latest addition to the series of economic pamphlets issued by the Trustees of the British Museum is that on *The Cockroach*,¹ by Mr. Frederick Laing, Assistant in the Department of Entomology. This disgusting creature, which, as every schoolboy knows, is neither black nor a beetle, and neither cock nor roach, has often been under

¹ *The Cockroach: Its Life-History and How to Deal with It*. By Frederick Laing, M.A., B.Sc. London: Printed by order of the Trustees of the British Museum, and sold at the British Museum and by B. Quaritch, Ltd., and Dulau and Co., Ltd. 1921. (Demy 8vo, pp. 18; 2 figures. 6d.)

² Gauthier; *Bull. Mém. Soc. Chir. Paris*, October, 1920, 1145.

suspicion as a carrier of disease, but the verdict hitherto has been "not proven," save in so far as it acts as a secondary host to a nematode, *Spiroptera neoplasticus*, which in certain circumstances can produce cancer in rats. With this part of the story of the cockroach, which was very fully related in our columns, Mr. Laing does not seem to have made himself sufficiently acquainted. Possibly, however, future research may incriminate the cockroach further, and it seems reasonable to suppose that the creature may infect food over which it crawls. Its only useful functions are that it removes dead animal matter and that it eats bed-bugs. Mr. Laing writes most attractively, and within the compass of 18 pages describes the habits and life-history of the common cockroach, of the misnamed German cockroach, and of the two other species—the American and the Australian—occasionally found in warehouses and hot-houses in this country. The most effective methods of getting rid of these domestic pests are set out in a practical manner in the concluding section. The illustrations could scarcely be bettered.

ABLATION OF OVARIES IN MAMMARY CANCER.

FROM time to time cases have been reported in which a remarkable retrogression of cancer of the breast has been observed after removal of the ovaries. The earliest cases, so far as we know, were two reported to the Edinburgh Medico-Chirurgical Society by Sir George Beatson in 1896, and recorded in our columns on June 6th of that year. The most recent of the kind seems to be one reported to the Académie de Médecine on March 2nd by Dr. Henry Reynès of Marseilles. He had had a case in which the same treatment was tried in 1904. His new case is that of a woman aged 45, in whom the menopause had not occurred. She was suffering from very advanced cancer of the breast; it was ulcerated and adherent to the chest: there were numerous enlarged glands in the axilla, and great oedema of the left upper limb. The local condition was quite inoperable. The ovaries were removed on October 1st, 1920; improvement immediately began, the ulceration healed, the breast became movable and the axillary glands, as well as the oedema of the arm, disappeared. The general condition, which had been very bad, cachexia being marked, greatly improved. A local operation for the removal of the tumour could have been performed, but the patient is very satisfied with her condition. In his comments Dr. Reynès suggested that in such a case arrest of the ovarian function might be brought about without operation by exposure to x rays.

THE GORGAS MEMORIAL.

SURGEON-GENERAL WILLIAM C. GORGAS, of the United States Army, died at the Queen Alexandra Military Hospital in London on July 4th, 1920. He had been taken ill while passing through this country on his way to the West Coast of Africa to investigate the prevalence there of yellow fever, a disease with which his name will ever be associated. The funeral service was held with full military honours in St. Paul's Cathedral; the body was then conveyed by an American warship to the United States and buried at Arlington, near Washington. In October last we stated that as a memorial to General Gorgas it had been proposed to establish in Panama an international institute for research in tropical diseases. It has now been announced by Rear Admiral Braisted, of the United States Navy, that plans are afoot to broaden the scope of the Gorgas Memorial Institute at Panama, so that it may be a research and teaching institute of international scope. According to our contemporary, the *Journal of the American Medical Association*, three American medical men are about to proceed to Panama to put the plan into effect as soon as the preliminary organization work is complete. The intention is that they shall begin research work in tropical medicine under

the superintendent of the hospital. Later the institute will have its own building adjoining the hospital, in front of which will be erected a statue of General Gorgas. Among the other institutions engaged in teaching and research in tropical medicine which have expressed their willingness to co-operate in furthering the aims of the Gorgas Memorial are Harvard and Johns Hopkins Universities, the Rockefeller Foundation, the University of California, the London School of Tropical Medicine, and the Liverpool School of Tropical Medicine. A more appropriate memorial could scarcely be conceived for the medical administrator who abolished yellow fever and malaria from the Panama Canal zone, and so made possible the construction of the great inter-oceanic waterway.

THE CHINESE RED CROSS SOCIETY.

AMONG the reports on national Red Cross societies presented to the recent International Conference at Geneva was one on the Chinese Red Cross Society. It is from the pen of Dr. B. Y. Wong, of the medical department of the Central Committee at Peking. It deals with the history of the society during the last ten years. During the first revolutionary outbreak in 1911 funds were raised in Shanghai, and Red Cross detachments were sent to Hankow under the direction of Dr. S. M. Cox, with Dr. B. Y. Wong as his adjutant, and also other centres of revolutionary activity. Another detachment was sent from Peking, under the leadership of Dr. J. C. Ferguson and Dr. Gibb, of Peking Union Medical College. In addition to attending to the wounded and rescuing the inmates of a blind asylum, the detachment raised burial corps, which were of great service. Much Red Cross work was done also at Nanking under the direction of Dr. Osgood. The society was again active during the civil war of 1913; it also came to the rescue of the population during a series of floods, the first due to the overflow of the river Wye, the second of the river Yu, and a third to a very serious inundation of the province of Fengtien. During the great war the society had few opportunities of being useful, but it gave aid during the Japanese operations against the Germans, and also at Vladivostok, where a hospital was established and nearly 17,000 patients treated. In 1918 Admiral Tsai was appointed vice-president, and the reorganization of the society was undertaken, but was interrupted by the call for help during the recent great famine in five densely populated north-western provinces. The society has three hospitals at Shanghai. One of these is the General Hospital, conducted in association with the American missions. It is a substantial building of red brick with stone foundations, on a site about two miles from the business centre of Shanghai. Cases are transported to it in motor ambulances; it is intended for the reception of serious cases, both surgical and medical, and is provided with a good operating theatre. The other two hospitals are on a smaller scale, but between them provide accommodation for over 300 cases. The society also has a small infectious hospital, which is open during the summer when cholera and intestinal disorders are prevalent.

AN ASTHMA CLINIC.

THE report of the Medical Board of the New York Hospital for 1920 states that in March of that year a special out-patient clinic for the study and treatment of asthma and hay fever was opened under the charge of Dr. Robert A. Cooke. This class, which is held twice weekly, has rapidly grown, so that from sixty to eighty patients are now treated at each session, and there is difficulty in providing adequate quarters in the limited space at the disposal of the out-patient department. The permanent value of this work cannot as yet be estimated, but the results so far attained are regarded as most encouraging and in striking contrast to those of former methods of treatment. Working on the assumption that such

conditions as asthma and hay fever are usually manifestations of a peculiar idiosyncrasy or hypersensitiveness on the part of the individual to certain substances taken into the body by inhalation or as food, the first stage in the treatment is the identification of the special substance or substances to which each patient is sensitive. This is accomplished by observing the local effects of the injection of extracts of a great variety of these substances into the patient's skin, in the manner described by Mr. Frank Coke in our issue of March 12th, 1921. If and when the offending agent is identified an effort is made to protect the patient from further exposure to it, or, should this not be possible, to immunize him against it by repeated subcutaneous injections of minute doses of its extract. Nine months' experience at the New York Hospital asthma clinic suggests that in the majority of asthmatic patients the trouble is due to the inhalation of the dandruff from the fur, feather, or hair of domestic animals. The growing work of this clinic has made heavy demands upon the subdepartment of immunology of the Pathological Department for the preparation of extracts of the various substances used in the diagnostic tests. As many as 130 substances are employed, and much skill and ingenuity have been needed to prepare extracts which are not only potent, but sterile and safe for inoculation. The importance attached to environment in the causation of many cases of asthma has led to the appointment of a social service worker to visit the homes and workshops of the patients and aid in carrying out the therapeutic measures advised at the clinic.

THE RÖNTGEN SOCIETY.

THE Silvanus Thompson Memorial Lecture of the Röntgen Society is to be delivered by Dr. A. V. Hill, Professor of Physiology in the University of Manchester, at the annual meeting of the Röntgen Society on May 19th; the subject of the lecture will be "Electrical instruments and phenomena in physiology." The society will hold its first meeting out of London at Manchester on Friday, May 6th, at 8 p.m., when, as already announced, Professor W. J. Bragg, Laugworthy Professor of Physics in the University of Manchester, will read a paper, and Professor A. V. Hill will give a demonstration. On the following day visits will be paid to works in the district. The society's annual exhibition will be held at the house of the Royal Photographic Society, 35, Russell Square, during June. Dr. Robert Knox, the president of the society, offers silver and bronze plaques as prizes for the best and second-best collection of four prints, the work of an assistant employed at a hospital or working for a qualified radiologist. This section will be open to persons who are not members of the Röntgen Society. The inaugural meeting of the Institute of Physics, which members of the Röntgen Society are invited to attend, will take place at the Institute of Civil Engineers, Great George Street, Westminster, on April 27th, at 6 p.m. The President, Sir Richard Glazebrook, K.C.B., formerly Director of the National Physical Laboratory, will be in the chair, and Sir J. J. Thomson, O.M., will deliver an address. It is hoped that Mr. A. J. Balfour will be present and take part in the proceedings.

PATHOLOGICAL RESEARCH APPLIED TO MEDICINE.

It has been arranged to give during the summer session a course of lectures at the Institute of Pathology and Research, St. Mary's Hospital, London, on pathological research in its relation to medicine. The first lecture will be given by the Principal, Sir Almoth Wright, M.D., F.R.S., on Thursday next, April 28th, at 4.30 p.m.; subsequent lectures will be given on the same day of the week and at the same hour. Among the distinguished men of science who have promised to take part in the course are Sir James Mackenzie, M.D., F.R.S., Professor W. Bulloch, M.D., F.R.S., Professor G. Dreyer, M.D., F.R.S.,

Dr. Leonard Hill, F.R.S., Dr. H. H. Dale, F.R.S., and Dr. J. A. Murray, Director of the Imperial Cancer Research Laboratories. The course will be open to all members of the profession and students. The full programme giving the subjects of each lecture will be published shortly.

EMERGENCY AMBULANCE PLANS.

In view of the recent threat of a strike of railway men and transport workers the Home Service Ambulance Committee of the Joint Council of the British Red Cross Society and the Order of St. John instructed the county directors that the fullest use should be made of the ambulances, both for the assistance of the authorities in dealing with casualties and for the maintenance of hospital supplies in the event of the failure of other transport facilities. In the instructions issued as regards the use of the ambulances in connexion with any disturbances, it was requested that regard should be had to the maintenance of the ordinary work of the vehicles, and that such arrangements should be made for co-ordination between adjacent ambulance stations that the least possible inconvenience should ensue to the hospitals and patients of the areas served. It was stipulated, with the concurrence of the military authorities, that the ambulances must remain entirely under the control of the county directors and must not be driven by enlisted men.

DR. HENRY HEAD will deliver the Croonian Lecture before the Royal Society on Thursday, May 5th. The subject is "Release of Function in the Nervous System."

PROFESSOR FREDERICK GOWLAND HOPKINS, M.B., F.R.C.P., F.R.S., who has been professor of biochemistry in the University of Cambridge since 1914, has been appointed to the newly-founded Sir William Dunn chair in that subject. The total amount of Sir William Dunn's benefaction for the establishment of an institute of chemistry was £165,000; of this, £25,000 was set apart for the endowment of the chair, and £10,000 to provide a salary for the second in command; £60,000 was to be spent on the erection of suitable laboratories, leaving, it was hoped, an income of about £3,000 a year for research and upkeep.

OWING to the threatened railway strike the Congress of Radiology and Physiotherapy, which had been arranged for April 14th, 15th and 16th, could not be held. At a meeting of the Executive, held on April 20th, it was decided to postpone the congress until next spring.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Post-Graduate Instruction.

THE Committee appointed by the Ministry of Health, with the Earl of Athlone as chairman, to consider the question of post-graduate instruction in medicine, has held a number of meetings and is approaching the completion of its work. It is not expected, however, that the report will be ready before next month.

Tuberculosis Bill.

Second Reading in the Commons.

Sir A. Mond, on April 13th, moved the second reading of the Public Health (Tuberculosis) Bill, the object of which is to enable the county and county borough councils to take up, as from April 30th, responsibilities for sanatorium treatment for tuberculosis, this being the date on which the duties of the Insurance Committees in this matter under the National Insurance Act of 1920 are ended.

Minister's Statement.

The Minister reminded the House that the county and borough councils had already been responsible for a large number of tuberculosis cases, and had treated many more

and non insured cases within their areas. It was the close propoed in the bill that these authorities should act in respect of both insured and non insured. Arrangements have been made in accordance with schemes or agreements approved by the Minister of Health or his predecessors, and Clause 1 of the bill provided that such arrangements should for its purpose be deemed adequate. Of the 145 county and borough councils in England and Wales 124 have acted, and the bill placed no fresh obligations upon them. Of the remaining 21, all but one had made some provision for the treatment of tuberculosis, but in two or three cases the provision extended only to dispensaries, and in others the arrangements of the councils for treatment in sanatoriums or hospitals did not provide fully for insured persons. In these cases the Insurance Committee at present met directly the needs of insured persons. He understood that the small number of councils who had not yet fallen into line were ready to do so if they understood that the obligations were statutory. In order to prevent the possibility of any local authority failing in its duty, there was a power in Subsection 2 of Clause 1 by which the Minister in such event might make large the authority with it. This

Mond said he knew that some doubt had been felt whether the powers given under Clause 2, Subsection 1, might not be used in such a way that if at any time the Exchequer contributions diminished the Minister might impose great burdens upon the local authorities. That was not intended, and if so desired he should be pleased to consider an amendment to remove that doubt. Power was to be given to local authorities to co-opt on their committees members from the Insurance Committees which had been doing such good work. To compel this course to be taken would, he thought, very much defeat the object in view, but he looked forward to invitations being given and to harmonious co-operation. He read a letter he had received from the Association of Municipal Corporations. A subcommittee who had considered the bill accepted the co-opt on provision only because it was optional. They would, it was stated, strongly object to this provision being made compulsory. Sir Alfred added that

either the position of the Welsh was met under the bill. He was ready to insert any further amendment to make the matter absolutely certain.

Mr. Ormsby Gore, in welcoming the measure, believed that the county and borough councils were willing co-operators but bad servants if the Ministry attempted to drive them. The campaign against tuberculosis required strategy. One of the lacunae was that tuberculosis was notifiable since 1912 to the district medical officer, but he had to pass on his information to the county medical officer, and he had to treat it as confidential. Thus his action was not very desirable.

After care also wanted for would, he was sure, be well advised to encourage the county councils administering the bill and the medical officers of health to stimulate in every way research and reports upon their experience, both scientific and administrative, so as to get every one keen on stamping out a disease of this kind. It was most important that officers who had been engaged in administering sanatorium benefit, with seven or eight of the working of it—medical turned off into other occupational indication should have been given some continuity of employment officers who had administered the benefit in the past.

Debate.

Mr. R. Richardson, on behalf of the Labour Party, also welcomed the bill. As to the scheme generally, he held that matters should not be left so much to the local authorities. This was a national question, and the expense ought not to be thrown on the local authorities. It was broadly correct to say that the poorer the area the more prevalent was this disease and the less able were the people there to cope with it owing to their financial position. The greatest defect of the bill was as regards after treatment. It ought to be an instruction to every local authority that it must have an After care Committee. That committee should include upon it the medical officer of the local authority or some such person. Every local authority ought also to provide an open air school for all children suffering from the disease, where pure milk could be provided.

Lieut. Colonel Raw commended the bill for several reasons, but for two in particular. One was that tuberculosis was preventable and should not exist in any civilized country, and the second was that it was curable. At present there were in England over 600,000 persons attacked by tuberculosis. England alone suffered in deaths between 50,000 and 60,000 persons per year from tuberculosis. He was certain that the health authorities were most anxious not only to give the very best tuberculosis, but to take every Minister of Health, to prevent a clause to enable members of pted should be mandatory and not permissive. Local committees should have the power to appoint an After care Committee—a statutory committee to see that the patient was enabled to carry on, in some degree, the sanatorium treatment. He suggested that the most important problem was the wage earning power of the man or woman afflicted. A man attacked by this disease was, in the best of circumstances, only a 50 per cent. man in wage earning

capacity. Means must be devised by which suitable occupation could be found for those men and women who had to some extent recovered, whereby they could earn a proper livelihood. Another important question was the isolation of advanced cases. One of the chief means by which a reduction of tuberculosis had been brought about was the fact that the Poor Law infirmaries isolated an enormous number of advanced cases. The infirmaries should be encouraged to continue this humane and necessary system of giving comfort and shelter to these afflicted people. There was also the question of sailors; wherever they landed the local authority should have power to give them whatever treatment they might require.

Mr. Trevelyan Thomson hoped that in Committee Clause 1 would be strengthened, for as it was drafted it meant that no matter how inefficient or incomplete an existing scheme might be it was to be deemed adequate after the passing of the bill. Coming to his own experience of work on an Insurance Committee at Middlesbrough, Mr. Thomson said that their funds being so limited they concentrated entirely on early cases, and it was found that 60 per cent. of the patients who had been dealt with were able to resume active work and take their places as physically fit. The advanced cases, notwithstanding that they were ignored, had not increased in number. They found that so far as their limited funds operated, the value of the money spent worked out in these proportions: For every £1 spent on after care, £2 was spent in the dispensary and £8 upon sanatoriums; in fact, eight times as much value was got for the money spent on after care as upon other forms of treatment. He appealed to the Minister to extend recognition to convalescent homes, which might not occupy palatial buildings and have a full staff of medical officers and nurses, but which were yielding an excellent return. He hoped, too, that more financial assistance might be given to the local authorities.

Captain Elliot recalled that Scotland had provided the precedent for this scheme—a precedent which had been working for a long time. Quoting the comparative statistics of deaths from tuberculosis and consumption in this country, he thought that a certain amount of the decrease of the last two years was undoubtedly due to the remedial measures introduced by the then Minister of Health, but a large amount of it was due to good trade. He warned all sections of the House—and was sure that every medical man would join in that warning—against the almost inevitable disturbance in our vital statistics which the present industrial crisis would bring about. Our vital statistics were very much better than those of any other country in Europe, and better almost than those of any other country in the world. In 1919 our death rate was 125.8, and in 1920 it was 112.8. In Prague, where the conditions were fairly comparable with those in our own country, the death rate was 336, in the city of Warsaw it was 591, in Vienna 490, and in Cracow 616. We had no special immunity against disease in this country. If we had a starving population, diseases, of which tuberculosis was one, would follow as surely as the rising and setting of the sun. He thought that the scheme of the bill afforded the best method of dealing with the matter. This was by a system of local administration with a grant in aid from a central authority, and it had proved its value in other affairs of public health in the country, as, for instance, in reducing the mortality of children. There was a splendid chance now of dealing with this evil. Influenza had swept out a large number of people who would probably have become acute cases of tuberculosis. Consequently they had a very low number of people in the country to-day actually in acute stages of tuberculosis; they could get it on the run if they could drive the attack home. In regard to after care, he thought the experience of the Ministry of Labour should be of the utmost value. What was wanted was a sort of disabled men's roll—some sort of national scheme for the reservation of a proportion of places in industry. In this connexion he made a special appeal to the Labour representatives. He suggested also that there should be some sort of a clearing house system before men were definitely marked off for sanatorium treatment; this would enable the whole medical science to be concentrated on a particular case, and then it could be determined definitely, after some residence in hospital, whether a person needed to start the treatment.

Major Molson hoped that the bill would be passed promptly, and that any great expense in the way of building would be avoided. He was not in favour of elaborate buildings, but of pushing forward to fulfil the pledge given so long ago for the efficient treatment of the great mass of people who needed it.

Major David Davies regretted that there was no financial clause in the bill. He thought it was intended that the financial arrangements which would come up in the Estimates for the Ministry of Health were to be based on the present arrangement. The local authorities paid 50 per cent. or half the deficit, and the remaining half was to come from the Treasury. He urged that the Treasury contribution should be two thirds.

Major Newman agreed that the measure was necessary, but asked what it was going to cost the tax- and rate payer.

Dr. Farquharson welcomed the bill, which he took as dealing solely with the question of institutional treatment for tuberculosis. As he read the finance of the bill something more than £400,000 would be available for the purpose. In his view sanatorium treatment at present was nothing more than an experiment. In his opinion the expense of the treatment by the results of the p

of methods of treatment, it was only one little stage of treatment which often came in, unfortunately, when treatment of any kind was more or less useless. He regarded the sanatorium

as an element of an educational agency, which the Ministry of Health now had at command. The Ministry had a duty more important than merely creating bureaucrats to dispense large sums of money. One fault he found with institutional treatment was that it induced a certain degree of passivity on the part of the patient. The After-care Association encouraged that passivity, when often all that was wanted was to rouse the patient to the knowledge that he was his own keeper, and that by simple attention to hygienic rules he could cease to be a burden upon his fellow men. Referring to the financial statistics of the bill, Dr. Farquharson pointed out that it transferred the onus of the incidence of payment for benefit given. Under the National Insurance Act the benefits derived from institutional treatment were paid for by the employers, by the State, and by the insured person himself, a portion of the contributions being allocated. Under this bill by a stroke of the pen the onus referred to was transferred to the local ratepayer and the income tax payer, the money previously applied for this purpose being absorbed in general insurance benefits. He thought that such financial readjustments should not appear as a side issue. He was opposed to the suggested amendment to compel county councils to co-opt members of committees; that this should be permissive was right and proper. Subject to these criticisms he welcomed the bill as filling up a gap left by the bill of 1920.

Mr. Lane-Fox, Sir W. Joynton-Hicks, Sir F. Blake, Sir F. Banbury, Lieutenant Commander Kenworthy, and Mr. Myers continued the discussion.

Sir A. Mond, in replying on the whole debate, said the total expense of the treatment of tuberculosis was estimated at £2,300,000, of which the Exchequer was bearing £1,300,000 and the local authorities were bearing £1,000,000. Another £100,000 had to be added to the Exchequer expenditure because that was the sum which would come on the Exchequer which was now being borne by the insurance vote. What was now being discussed was £300,000, which was not a fixed amount but an approximate amount. It was the contribution which would have been received from the Insurance Committees by the local authorities. The local authorities were actually receiving from the Exchequer the full equivalent of the amount available in 1920. The sum of £300,000 was to be taken as an estimate. The proper time for discussing the financial aspects of the bill would be on the Estimates. Lieut.-Colonel Fremantle inquired if the proposals of the bill of last year dealing with sanatoriums for soldiers in village settlements would be included in this bill. Sir A. Mond said they certainly would not.

The bill was then given a second reading.

The Dogs Bill.

One effect of the preoccupation of parliamentary minds with the coal crisis was that, the business of the House of Commons being taken as usual, there was a chance that the bills of private members on the agenda for April 15th must be passed at a rapid rate and without much attention being given to them. The medical group, however, kept a vigilant eye for the Dogs Bill introduced by Sir Frederick Banbury, which was down for second reading as a late order. The withdrawal of various members from the debating chamber at one o'clock ensured a count and an adjournment until half-past three. Then the House received the important statement by the Prime Minister regarding the coal conference and no further business was taken.

The Medical Staff of the Ministry of Health.—Sir A. Mond, in answer to Sir T. Fraser, said, on April 13th, that the total number of medical men on the staff of the department (including two part-time specialist officers) was one hundred—namely, sixty-three at headquarters and thirty-seven in regional offices; the salaries of the heads £51,549 3s., and the war per annum. The salaries on March 31st, 1921, all officers were inclusive men employed by the thirty-one, and their actual salaries in that year amounted to £20,571 15s. 9d. For purposes of comparison, however, the medical staff of the National Health Insurance Commissions (England and Wales) must be added to this, as their functions are now performed by medical officers of the Ministry. In 1914 this staff numbered eight (including the deputy-chairmen in England and Wales), and their salaries totalled £6,300. The total number of medical men in the two departments in 1914 was, therefore, thirty-nine, and the cost £26,871 15s. 9d. Sir W. Joynton-Hicks asked if there was any intention to reduce what was apparently an over-weighted staff to the pre-war number. Lieut.-Colonel Fremantle inquired whether it was not the fact that this staff had always been insufficient for protecting the health of the nation. Sir A. Mond replied that he had not had an opportunity of going into the question, and could not therefore offer any opinion in regard to it.

Superannuation of Islington's Medical Officer.—Lieut.-Colonel Fremantle asked, on April 13th, whether the Islington Borough Council was proposing to superannuate their medical officer of health after thirty-nine years' efficient and energetic service (twenty-nine at Islington) at a rate not fixed by scale

and far below that usually granted to executive officers. He put it to the Minister that the Superannuation (Metropolitan) Act, 1866, provided for the payment of superannuation at the rate of one-sixtieth of salary for every year of service, and that the Islington Council had adopted the Act for superannuating roadmen, scavengers and other labourers. Sir A. Mond said he was making inquiries into the case.

Public Health Officers (No. 2) Bill.—This measure was read a second time on April 14th and committed to a Standing Committee. This is the bill introduced by Sir Philip Magnus at the request of the British Medical Association, and is designed to give all medical officers of health and sanitary inspectors security in their tenure of office similar to that enjoyed by Poor Law medical officers, metropolitan medical officers of health, and medical officers of health appointed by county councils.

Criminal Law Amendment Bill.—Mr. Chamberlain, replying to Lady Astor on April 12th, said that if he found that the Criminal Law Amendment Bill could be treated as a non-controversial measure the Government would endeavour to facilitate the passage towards the end of the session.

Encephalitis Lethargica.—Sir A. Mond, on April 13th, informed Mr. Gilbert that 1,572 cases of encephalitis lethargica had been reported in England and Wales, between April 1st, 1920, and March 31st, 1921. The deaths from this disease during the same period, so far as was known at present, amounted to 495. The disease was made compulsorily notifiable on January 1st, 1919, and since then special reports had been received from medical officers of health on practically all the cases which had been notified, while special inquiries had been made and advice had been given by medical officers of the Ministry in suitable cases. Simultaneously the pathology of the disease was being studied in association with the Medical Research Council.

Admiralty Surgeons' Fees.—Mr. Amery informed Captain Elliot that the revised scales of fees for Admiralty surgeons had now been promulgated in a Fleet Order, with the exception of those for medical examinations.

Bellahouston Hospital, Glasgow.—In Maclean, a statement was made that he had called for a pension that unless the report satisfied him that the allegations were unfounded, he would hold an inquiry into the administration of the hospital forthwith.

Medical Officers' Pay in India.—In answer to Lieut.-Colonel Guinness, on April 14th, Mr. Montagu said that the pay of R.A.M.C. officers in India was increased in March, 1920, with effect from July 1st, 1919. Consequent on an increase of pay granted to officers of the Indian Medical Service, with effect from January 1st, 1920, a further increase had been granted to R.A.M.C. officers, with effect from the same date.

Nurses' Registration Acts.—Mr. T. Griffiths asked, on April 18th, whether the General Nursing Council for Scotland had so far refused to consult with the English Council before making rules with respect to conditions of admission to the register, as required by the Scottish Act, Section 3, Subsection (3); and, if so, whether he would insist on such a consultation so that the English Council may be in a position to present its rules for his approval, and to open the register under conditions securing a uniform standard of qualification in all parts of the United Kingdom, as provided in the Nurses' Registration Acts. Sir A. Mond replied that he understood that the Scottish Nursing Council had not refused to consult with the English Council; but that, in view of the small number of outstanding points on the rules for the admission of existing nurses to the register, had suggested that the conference should be deferred until the draft rules for the admission of future nurses were ready for discussion. In any case he had no jurisdiction over the Scottish Council, though he agreed that it was important to secure a uniform standard of registration in all parts of the United Kingdom.

The Dentists Bill.—Mr. Raffan asked, on April 13th, if it was still the intention of the Government to introduce a measure this session to carry out the recommendations of the Departmental Committee on the Dentists Act. Sir A. Mond said he was afraid that, owing to the congestion of the Government's business, legislation on this subject would not be practicable during the present session. Mr. Raffan recalled that Dr. Addison had promised that a bill should be introduced if there were general agreement, and he asked whether on such assurance the present Minister of Health would reconsider the matter. Sir A. Mond said he had no intention to introduce a bill this session. The programme of legislation was very much upset already, and he was informed there was very little chance of any agreement. He would, of course, be glad to look into the matter again, but he did not know how any group of members could give him an assurance of an agreement, and he was sure that the House did not want an autumn session. He would be pleased, however, to receive representations from members of Parliament regarding the position. Arrangements have been made for a meeting one day next week of the Parliamentary Medical Group and of members of the Incorporated Dental Society to consider what steps can be taken to assist the progress of the bill. Captain Elliot and Mr. Raffan are making the arrangements.

THE MALE VENEREAL CLINIC AT THE ROYAL INFIRMARY, LEICESTER.

AN ACCOUNT OF ITS ORIGIN, DEVELOPMENT, AND WORK.

BY

HENRY J. BLAKESLEY, F.R.C.S.,
MAJOR R.A.M.C.T.,

HONORARY CONSULTING SURGEON, LEICESTER ROYAL INFIRMARY;
MEDICAL OFFICER IN CHARGE OF THE MALE VENEREAL CLINIC, LEICESTER ROYAL INFIRMARY.

THE clinic for diagnosis and treatment of venereal diseases in the male was opened at the Royal Infirmary, Leicester, on March 2nd, 1917. A portion of the out-patient department was set apart by the board of governors of the infirmary. Certain fixed days and hours were allotted, at which times no other out-patients attended, ensuring as far as possible privacy for patients suffering from or seeking advice regarding venereal diseases. A consulting room, two examination rooms, and an irrigation room fitted with sterilizer, hot and cold water, sink, etc., were available.

As the out-patient department is congested with general medical, surgical, and special work no further time can be allotted for extending the number of hours of the venereal clinics. Plans have been prepared and a new building exclusively reserved for the treatment of venereal diseases will shortly be erected. Complete privacy will be secured and all facilities afforded for the carrying out of all ordinary and special treatment under the most favourable conditions.

About the end of 1917 two small wards, accommodating four in patients, were provided and equipped by the infirmary authorities for men, completely isolated from the general hospital, and they have been in constant occupation up to the present time.

Two clinics of two to three hours each in duration were held weekly during the year 1917. On January 1st, 1918, three clinics a week were deemed necessary, one of which was reserved exclusively for the treatment of gonorrhoea; and on November 1st, 1919, it was found that the holding of a fourth clinic per week was essential in order to cope with the number of patients applying for treatment, this being more than double that of the preceding year.

During the first year the staff consisted of the medical officer in charge—who personally carried out the whole of the treatment, both general and technical—assisted by an inadequately trained male nurse. About the middle of 1918 one of the resident house surgeons of the infirmary was allowed to assist at two clinics per week, and his services were utilized to carry out the technical treatment of gonorrhoea. This arrangement obtained until July, 1919, when the largely increased number of patients attending rendered it necessary that the house surgeon should attend all the clinics. After a few months it was found that his attendance at all clinics so materially interfered with his ordinary duties as house surgeon that the board of governors, with the approval of the Ministry of Health and the City and County Councils, appointed a fully qualified medical man as part-time assistant medical officer to the Male Venereal Department.

The two medical officers carry out the whole of the work of the department, assisted by a highly efficient male nurse and a well trained hospital porter. In addition to his duties at the clinics the male nurse is in nursing charge of the male venereal wards, and he is on duty from 8 a.m. to 8 p.m. for the carrying out of measures (for the prevention of venereal disease) and the giving of irrigations to such cases of gonorrhoea as apply in the intervals between the hours of the recognized clinics.

Summary of Work Done.

The work done in the three years and four months from March 1st, 1917, to June 30th, 1920, comprises:

1,885 new patients, 628 of whom were suffering from syphilis and 1,052 from gonorrhoea; 205 were found after clinical and bacteriological examinations not to be suffering from venereal disease, and 86 were proved to be suffering from both diseases. Renewed attendances numbered. In 1917, 2,583; in 1918, 5,021; in 1919, 9,315, and in 1920 (six months), 5,942.

During the ten months of 1917, 287 new patients applied for treatment at the clinic, 97 proving to be suffering from syphilis and 161 from gonorrhoea.

During the year 1918, 350 new patients applied, 121 suffering from syphilis and 210 from gonorrhoea.

During the year 1919, 852 new patients applied, 266 suffering from syphilis and 495 from gonorrhoea.

During the first six months of 1920, 386 new patients applied, 141 suffering from syphilis and 186 from gonorrhoea. In about 10 per cent of the total venereal disease was not proven, and some 5 per cent were proved to have both syphilis and gonorrhoea.

The marked increase of new patients during 1919 may be attributed to the fact that in that year large numbers of men were demobilized, many of whom contracted venereal disease shortly after returning to civil life, and a considerable number were cases contracted whilst on active service which had been treated but still showed definite signs of active disease. The renewed attendances of patients coming for treatment have increased practically in proportion to the number of new patients.

Throughout the clinic the strictest antiseptic precautions are observed. All patients are enjoined to observe the following general rules of life during treatment:

No alcohol, total abstinence from coitus or sexual excitement; care and discretion in diet, careful attention to action of bowels to ensure free daily evacuation, outdoor and healthy exercise, with specific limitations, avoidance of overheat and overcrowded places (cinemas, music halls, billiard rooms, etc.), early hours to ensure sufficient rest, general bodily cleanliness and sufficient and warm clothing.

Specimens, such as smears, blood for Wassermann test, serum for examination, spirochaetes, etc., are taken from all patients on admission, and are repeated at short intervals during the course of treatment. All specimens are submitted to the pathologist attached to the infirmary for examination and report, and the clinical treatment is controlled and modified in detail by such pathological report.

Treatment of Syphilis.

The treatment of syphilis, as carried out in the clinic, consists of weekly injections, intravenous injections of salvarsan substitute alternating with intramuscular injections of metallic mercury.

Neo-kharsivan is the substitute now exclusively given, others having been tried and discarded as not proving so satisfactory, and the mercury is given in the form of Lambkin's cream. Ten injections of each constitute a course. The usual doses given are neo-kharsivan 0.6 gram making 6 grams in all (for a course) for an adult patient of average weight and condition. Smaller doses are given in cases of youth, under weight, old age, deterioration of arteries, and in the constitutionally feeble. Larger doses, namely, 0.75 gram, and 0.9 gram, are administered to others of more than average weight, height, and robust constitution; and metallic mercury 2 grains, making 20 grains for the course.

In addition to the above, mercury is given internally by the mouth in the form of pil. hyd. creta grains 2 twice a day.

The gravity method is employed for the administration of salvarsan substitute, the apparatus consisting of a simple glass container, rubber tubing with glass window and Bailey's holder and needle. The vein of choice is the median cephalic. Lambkin's cream is given with a Record syringe with a steel intramuscular needle of at least one and a half inches in length. This is given in the buttock, the site chosen being the intercellular tissue between the glutei muscles.

All apparatus employed is sterilized by boiling, a fresh needle which has been immersed in spirit after boiling being used for each injection. The skin is rendered aseptic by tincture of iodine or 2 per cent. watery solution of picric acid. The efficiency of the antiseptic precautions observed is proved by the fact that in 6,236 injections not a trace of sepsis has occurred.

Treatment after Course.—At the end of the course as described all treatment is suspended for five weeks, and at the end of that time the blood is taken and a Wassermann test is done. If the result be negative, pil. hyd. creta grains 2 is given twice daily for one month, and then stopped for one month, at the end of which a second Wassermann test is done. If this also prove negative the pills are repeated for one month, stopped for two months, and a third Wassermann done. Should this also prove negative, the pills are repeated for one month, stopped for two months, and a fourth Wassermann test is done. Should the patient's blood still remain negative no further treatment is given, but Wassermann tests are performed at intervals of three to six months until after two years from the termination of treatment by injection. If the result of any Wassermann test after the first course of treatment prove positive the patient is given pil. hyd. creta grains 2 for two months from the last second course is administered.

The number of doses varying according to whether the Wassermann reaction shows a low or high degree of positivity. At the end of the second course the same procedure is followed as after the first. Should any further positive Wassermann occur a third and, if necessary, a fourth course is given.

Tests of Cure.—The standard test of cure for syphilis adopted in the clinic is: In cases that commence treatment within two months of the appearance of the primary sore, negative Wassermann tests repeated at intervals, extending to two years from cessation of treatment with the absence of all objective symptoms. In cases commencing treatment after a

longer period than two months from the appearance of sore, negative Wassermann tests repeated at intervals for three or even four years after cessation of all treatment.

Treatment of Gonorrhoea.

The methods adopted for treatment of gonorrhoea comprise irrigations, instrumentation, massage, etc., at the clinics, carried out entirely by the medical officer, and home treatment in the intervals of attendance at the clinics by the patient himself, as instructed by the medical officer, together with the administration of suitable internal medication. Every facility and encouragement is given for gonorrhoea patients to attend daily for irrigations, but as practically all patients continue in full work during their course of treatment it is in most cases impossible for them to attend more than once or twice a week, and home treatment by syringe is ordered; all patients are individually instructed in the method to be carried out.

Each patient is provided with a half-ounce glass syringe and a bottle of solution of potassium permanganate, which, when mixed as directed, equals 1 in 4,000. This he is instructed to use in the following manner:

Wash hands; wash penis; pass urine; mix lotion; fill syringe; inject half a syringe into urethra and retain half minute; inject remaining half syringe, and again retain half minute. This method of using syringe is repeated thrice, resulting in 2 drachms of the lotion being injected into the urethra (six times at each sitting).

The whole of the above formula is to be carried out three times a day. The patient is further advised to wash the penis with soap and water four or five times a day. In addition he is advised to drink three pints of water daily; abstain from horse riding, cycling, motor cycling, football, and all violent exercise during the acute and subacute stages; observe great care by washing of the hands after each manipulation of the penis, to prevent infection of his own eyes; and take all precautions against conveyance of the disease to others by using separate towels, etc.

During the period March 1917 to June 1920, 14,311 irrigations were given for gonorrhoea, of which approximately 20 per cent. were irrigations of the anterior urethra only, and 80 per cent. irrigations of the anterior and posterior urethra. In addition to irrigation, further methods of treatment in the form of penile and prostatic massage, passage of metal sounds, instillations of solutions of silver compounds, etc., were given when indicated by the objective symptoms in each individual case. Urethroscopic inspection and dilatation with Kollmann's dilator has been practised in a comparatively small number of cases, but owing to the limited periods during which the out-patient department is available, it has been found impossible to apply these methods of treatment to many cases for which it would probably have been beneficial. Autogenous vaccines have been prepared and administered in a few selected cases of chronic gonorrhoea without evident benefit.

Irrigating Solutions.—The solutions used for irrigations were pot. permang. in strengths of 1 in 6000 for acute to 1 in 2000 for chronic cases. Solution of oxycyanide of mercury, strength 1 in 2000, and hypertonic saline solutions were also used for chronic cases. All solutions were freshly made and were maintained at a temperature of about 104° F., a thermometer being used to check this.

Standard of Cure.—The standard of cure adopted in the clinic for gonorrhoea is: Three negative smears in which pus cells can be found, taken at intervals of 24 hours after all treatment has been discontinued. After all objective symptoms for three days having been taken after thorough cleansing the hands, prepuce and meatus with soap, and thorough and careful massage of the prostate for two minutes. The patient is instructed to hold his urine for at least four hours before presenting himself for test.

Clinical Effects during Treatment of Syphilis.

In 762 cases diagnosed as true syphilis, 7 cases of dermatitis, 8 cases of jaundice, and 1 of haemoptysis occurred. Of these, 4 cases were admitted to the wards, 2 being cases of jaundice in a severe degree and 2 of general and severe dermatitis. All have recovered. The two cases of dermatitis have given negative Wassermann reactions up to the present date. The remaining cases were trivial, not entailing discontinuance of their employment. They quickly recovered under suitable medical treatment.

Complications of Gonorrhoea.

The following complications of gonorrhoea were observed in patients applying for treatment:

Epididymitis, 5; rheumatism, 4; stricture, 4; paraphimosis, 4; acute prostatitis, 2; perineal abscess, 2; warts, 2—total, 23.

The following complications arose during treatment:

Epididymitis, 10; retention of urine, 1.

These figures summarized show that all complications arising both before and during treatment amounted to 5.23 per cent. of cases of gonorrhoea; that the percentage of cases of epididymitis occurring in treated and untreated cases of gonorrhoea amounts to 1.45, whilst cases of epididymitis occurring after treatment had been commenced amount to 0.95 per cent.*

Comparison of Civil with Military Practice.

Patients under discipline and control are confined to hospital, and to bed if necessary, thus avoiding the conditions and actions detrimental to recovery, such as alcohol, sexual indulgence, violent exercise, unhealthy surroundings, etc. Nearly all civil patients are compelled by force of circumstances to continue their employment, whether detrimental or otherwise to the course of their disease. Furthermore, whilst military patients are compelled to continue treatment until discharged, out of 1,913 civil patients treated at the Royal Infirmary, no less than 1,035 discontinued treatment voluntarily, and out of this latter number, 303 made less than four attendances at the clinic.

The incidence of attendance is made more difficult in the provincial towns as compared with metropolitan areas by reason of the fact that the workers live and work in close relation with each other, and are known to each other to a much larger extent than in London, where a very large proportion live at a considerable distance from their work, and consequently can attend the provided clinics with greater privacy.

It will be observed that in the foregoing account of the work carried out at the Male Venereal Clinic of the Leicester Royal Infirmary no attempt has been made to show results from the standpoint of cure. This is intentional for the following reasons:

1. The increased and increasing knowledge of these diseases has proved their intractability, and consequently the period of three and a half years is too short to enable one to be dogmatic.
2. Large numbers of patients voluntarily ceased attendance, and it may be presumed that the greater proportion of these did so because all signs and symptoms of their disease had disappeared, though no opportunity was given for further bacteriological examination to verify the fact of recovery or otherwise.
3. The adoption during the past eighteen months of many methods of treatment which have now become recognized as routine practice, which in the early days of the clinic were in a more or less experimental stage, will undoubtedly tend to produce effective results in the near future, but they have not been in operation long enough to warrant definitely reliable statistics.
4. In civil life no means exist of ensuring regular and constant attendance for treatment and examination; by this alone can cure be reasonably expected in the majority of cases.

An extremely gratifying feature of the clinic is the large voluntary attendance of old cases for regular treatment, an attendance which is increasing month by month. Many of the men come long distances, even as much as fifteen to twenty miles, at considerable expense to themselves, both in money for train fares and time for treatment once a week, and in many cases still more often; whilst large numbers of the cases resident in the town attend every day the clinic is open.

The men rapidly show a very marked improvement in general health, and the clinical and bacteriological signs show very encouraging results, although not yet definite enough to give statistics. The appointment twelve months ago of a permanent assistant medical officer, who is devoting his whole time to venereal work, has been followed by very happy results. As stated above, his services at the clinic are utilized chiefly in the treatment of gonorrhoea, and since his appointment all technical treatment for this disease has been personally carried out by him or by myself. The men attending show their appreciation of our efforts, and the congenial tone which pervades the clinic has been considerably promoted and sustained by the loyal support I have received from Dr. Atkinson, my assistant medical officer, and the lay assistants. I am also greatly indebted to Dr. Atkinson for the collating of detailed figures and other work in the compiling of this paper. If these clinics are to be successful in attracting the continued attendance of patients until they become non-infectious, it will be due to the pains-taking supervision by the medical officers of all technical treatment, and the development of a tone of confidence and privacy.

*In an analysis of 50,000 cases of gonorrhoea published in Dr. Lush's recent work the total number of all complications was 7 per cent. approximately; of cases of epididymitis, 5.5 per cent.; and of epididymitis after treatment commenced, less than 2 per cent. (1.83).

England and Wales.

STREET ACCIDENTS IN LONDON.

THE usual quarterly return has been issued by the Home Office showing the number of accidents to persons or property known to the police to have been caused by bicycles or horses in the streets in the metropolitan area during the year 1920, and stating the number of persons killed. The figures are analysed according to the type of vehicle causing the accident, and the respective quarter in which they occurred. During the year 657 persons were killed, of whom 564 were killed by mechanically-propelled vehicles, 72 by horse-drawn vehicles or horses, and 19 by pedal cycles. Mechanically-propelled vehicles used for trade and commercial purposes were responsible for 216 deaths, private motor cars for 166, omnibuses and trams for 120, motor cycles for 53 and motor cabs for 27. The total number of accidents to persons or property during the year was 49,824. Of these more than 18,000 were caused by trade and commercial vehicles of one kind or another and 9,683 by private motor cars. The last quarter of the year was the least fruitful in accidents, fatal or otherwise. The horse, unaccompanied by any vehicle, was implicated in 151 accidents to persons or property, with a toll of three deaths. The traction engine was even less destructive, producing only forty-three accidents and no deaths. Horse-drawn omnibuses and trams have 100 entries in every column from which it may be inferred that they are now extinct in the metropolitan area; but the horse-drawn cab is debited with eighty-one non-fatal accidents, and the brougham with 376 accidents and one death.

LIVERPOOL HOSPITAL FOR CHILDREN.

The report for 1920 of the Liverpool Hospital for Children at Leasowe gives some interesting statistics of results. A criticism which is often passed upon statistics on such a hospital is that they are of little value unless followed by others showing the condition after a considerable period of time of those cases which have been discharged under the heading of "disease arrested." Dr. Hartley Martin, senior medical officer of the hospital, undertook, therefore, to follow up the Liverpool cases after discharge, and in order to do this an after-care clinic, held once a week, was established. Of 84 cases discharged "disease arrested" in 1919, 80 were traced, and of the 80 in January, 1921, 75 were well and 5 had shown recurrence of the disease. Of the 75 cases, which comprised cases of tuberculosis of the spine, hip, knee, and tuberculous arthritis, adenitis, and peritonitis, all but one were either attending school or in healthy employment, none of them being in special homes or workshops for the crippled. Such figures are distinctly encouraging in the treatment of surgical tuberculosis.

LEICESTER ROYAL INFIRMARY.

This year is the one hundred and fiftieth anniversary of the foundation of Leicester Royal Infirmary, and in the annual report for 1920 the rapid progress of the hospital during the last two decades is surveyed. This year the building of a new wing of the hospital with accommodation for 93 in-patients has been begun; when this is completed the available accommodation will be approximately 400 beds; to accommodate the necessary number of additional nurses a new wing is being added to the nurses' home, containing 66 bedrooms. During 1920 a special orthopaedic department and a new pathological department were opened, so that it is evident that the administration of the Leicester Royal Infirmary is both energetic and enterprising, and has brought the institution well into the front rank of modern hospitals. The report points out how admirably Leicestershire is situated to inaugurate a scheme of medical service such as was foreshadowed in the report of Lord Dawson's committee. The populous centres of the county are, generally speaking, about equidistant from Leicester, and a satisfactory motor ambulance service could quickly link up the county institutions with the county hospital. The board indicates its readiness to

consider this important question if the county areas appear to consider the co-ordinated service would be a benefit to the community. In regard to the finances of the year the large part that is played in regard to the financial side of the Leicester Royal Infirmary by its Hospital Saturday Fund is well known, and the report draws attention to the fact that whereas last year this fund amounted to over £20,000, this year it reaches the total of no less than £32,666. In view of the many difficulties of these times the Board of the Leicester Royal Infirmary must be congratulated on being able to present a satisfactory account of its finances, with no diminution, but rather an increase, of its activities.

POST-GRADUATE STUDY IN BRISTOL.

In connexion with the University of Bristol post-graduate studies a series of weekly clinical demonstrations will take place, during May and June, at the Bristol Royal Infirmary and General Hospital alternately on Wednesdays from 2.30 to 3.30 p.m. The demonstrations will include medical, surgical, eye, and skin cases, and the fee is two guineas, which will include admission for instruction for one month to all the departments of the clinical institutes included in the University. In addition, other post-graduate facilities are available in Bristol, since qualified medical practitioners may be appointed as clinical assistants in all branches of hospital practice for a period of one or more months, at a fee of three guineas a month; where the practitioners are unable to attend daily for a month they may extend the thirty attendances over any period up to six months. Inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Pathological Department, University of Bristol.

Scotland.

STUDENTS' FEES AT GLASGOW.

THE report of the Business Committee of the General Council of Glasgow University, which will be presented to the half-yearly meeting next week, makes special reference to the question of raising the class fees of students. As already announced in this column, the University Courts have agreed that the increases shall, as far as practicable, be uniform in the four Scottish universities, and notice has been given that the new scale of fees will come into operation at the beginning of the October session. The adjustment of the scale of increases in the University of Glasgow is at present under consideration by a committee of the Court. The coming into operation of the new scale will, it is said, raise a serious problem in connexion with the grants made by the Carnegie Trustees towards the payment of students' class fees. "The conclusion can hardly be avoided that there are students taking advantage of the Trust whose circumstances do not warrant assistance being given." The suggestion is made that it might be well to revise the basis of the grants in each faculty, and "unless very strong reason can be given, the benefit of the Trust should not be given to anyone who has not gained the leaving certificate or passed the preliminary examination." At the beginning of the academic year 1920-21 the Business Committee reduced by £1 in each faculty the scale of allocation.

FERGUSON CHEMICAL LIBRARY.

On the recommendation of the Library Committee, the University Court of Glasgow has decided to acquire the valuable chemical library of the late Professor John Ferguson, who for more than forty years held the chair of chemistry in the university. The chemical section of the library contains, in round figures, 9,300 volumes, 1,400 pamphlets, and 300 manuscripts. In addition to the great number of volumes on alchemy, chemistry, astrology, folklore, etc., and on technical processes, there are works on early medicine and pharmacy, and on spas and mineral waters. Lastly, it should be noted that the library contains some 130 copies of books printed in the fifteenth century.

Correspondence.

THE SCIENCE OF ETIOLOGY, OR THE NEW
EPIDEMIOLOGY.

SIR,—Since "not inquiring too strictly into the specific differentiae of disease" means nothing more than the study of etiological momenta common to disease groups, Dr. Greenwood is to be congratulated on having cleared up a misunderstanding. As regards the final paragraph of his letter in your issue of April 16th, I would venture to remind him that the problem of causation is assuredly not of less interest to the clinician and to the bacteriologist than to the investigator, however hard-working, who devotes himself to the study of epidemics. Preventive medicine is the pride and aim of us all, and contributions to the growing science of etiology, upon which it is based, cannot be too closely scrutinized.—I am, etc.,

April 17th.

THE BACTERIOLOGIST IN QUESTION.

"ETHANESAL" OR ETHER.

SIR,—I used this new anaesthetic, "ethanesal" (BRITISH MEDICAL JOURNAL, April 16th, 1921, p. 565), recently in a case of hysterectomy. The patient was a nullipara and a good subject for the anaesthesia, which was preceded by a hypodermic injection of morphine gr. 1/6, with atropine gr. 1/150, forty-five minutes before the operation was timed to begin. Anaesthesia was begun with a mixture of chloroform and ordinary ether in equal parts for three minutes and continued with ethanesal on an open mask covered with eight layers of gauze kept covered with a twofold towel. She was ready for the surgeon in seven minutes; the operation did not, however, begin for another five minutes, so that when he began she had been having the anaesthetic for fifteen minutes and was apparently deeply under. During the opening of the abdomen the anaesthesia was satisfactory, but from then onwards I found it very difficult to keep her in a state of real surgical anaesthesia; even by using 1 oz. every five minutes I could not secure quiet breathing and full muscular relaxation, so that after fifteen minutes I changed to ordinary ether, when both these conditions were easily realized and kept for the rest of the operation. My first impression, therefore, of the choice of ethanesal or ordinary ether is that I shall prefer the latter for the following reasons: (a) Ethanesal anaesthesia would be too light for abdominal and rectal anaesthesia; (b) it would be nearly twice as costly as ether; and (c) post-operative vomiting is rarely troublesome with open ether anaesthesia.—I am, etc.,

C. CHARNOCK SMITH, M.R.C.S., L.R.C.P.

Hastings, April 18th.

EVOLUTION AND DISEASE.

SIR,—Dr. J. T. C. Nash's letter on Evolution and Disease, in the BRITISH MEDICAL JOURNAL for April 9th, is an opportune appeal to biologists, and more particularly to bacteriologists, for greater tolerance towards those who make what Tyndall would have termed a scientific use of the imagination in their dealings with the problems of science.

Intolerance and bigotry are out of place in any department of science, but especially in medical science, whose workers are, or should be, familiar with, and therefore sympathetic towards, the little weaknesses of human nature. Certainly as a class scientific men are less bigoted and more tolerant than any other class, despite the tendency of specialization to produce that type of mind that cannot see the wood for the trees, but now and again they allow the cloven hoof of bigotry and intolerance to appear. Two notable and very relevant examples of this deplorable phase of mind may be recalled. When Professor Tyndall, in his lectures on "Dust and Disease," suggested that atmospheric dust might be agencies in the production of the wrath and jealousy of medical men, who apparently resented the incursion of the pure physicist into the realms of medicine. In a leading article in the *Lancet* a writer thus fulminated his displeasure:

"It is lamentable that an eminent public teacher, when speaking on a subject of which he can know next to nothing, should place his opinion in opposition to that entertained by all those who are most capable of judging."

Again, when Charlton Bastian, himself a distinguished Fellow of the Royal Society, submitted to the society a paper dealing with abiogenesis, not only was the paper declined but the particular member of the committee responsible for its rejection flatly refused to look at the specimens Dr. Bastian had brought.

I quite agree with Dr. Nash's general contentions concerning a probable relationship between certain diseases and a faculty of involution and evolution on the part of the causative micro-organisms. In the BRITISH MEDICAL JOURNAL for October 14th, 1905, I published the case of a robust and temperate young sailor who sustained a severe blow over the left side of his chest, and who on the following day fell ill with, and subsequently exhibited all the classic signs and symptoms of, acute pneumonia of the left lung. In this case the coincidence between trauma and pneumococcal infection was so striking that I ventured the following suggestions, the italics being now inserted:

"In cases of this nature I incline to the assumption that an involution form of the specific pneumococcus finding itself, if I may be allowed the expression, in a favourable environment, to wit, damaged lung tissue, undergoes a rapid evolution into the higher and more virulent variety associated with acute pneumonia. This latter variety subsequently either reverts to the lower and more primitive saprophytic type, should the host die of the disease, or it succumbs to phagocytosis during recovery (of the host)."

In the following number of the JOURNAL Dr. Frederick C. Forster stated that he had, in the previous seven years, treated five precisely similar cases. Apart from the well-known capacity of certain bacteria to undergo evolution and involution, is it not more than probable that the sudden appearance of new diseases in the past may ultimately be proved to be due to a mutation of some harmless saprophytic bacterium into the parasitic type? Seeing that mutations do occur in the plant and animal world, as amply proved by De Vries in the case of the evening primrose, *Oenothera*, and by Morgau in the case of the fly *Drosophila*, we may reasonably expect them to occur in the bacterial world which was the forerunner of both.—I am, etc.,

C. MARSH BEADNELL, R.N.,

R.N. Hospital, Chatham, April 11th.

Surgeon Captain R.N.

AN OPERATION PERFORMED UNDER
DIFFICULTIES.

SIR,—The difficulties besetting an operator, apart from those of a physical or anatomical nature, are usually determined by the time the emergency arises and the place where it occurs. A sudden emergency demands prompt action, and a remote situation precludes any hope of obtaining help or instruments. Two emergencies placed me in the position of having to determine on prompt action without much prospect of success, and an even stronger prospect of a dire result should no action at all be taken.

The first emergency was the movement of troops to a remote place in the Northern Territories of the Gold Coast, in lat. 11.50 N. and long. 0.40 W. The patient was a native clerk's wife, who had accompanied the troops, and not only were the surgical instruments available few in number, but also they were not applicable to the case in question—an incomplete abortion with severe haemorrhage. It was impossible to send for instruments from the nearest station where they were available in time to be of any service, and something must be done. The two emergencies—troops recently moved, with a limited surgical equipment, and the wholly unexpected occurrence of a gynaecological case in that situation—were perhaps unique, and certainly embarrassing.

From the first day I set foot on the Gold Coast I made a point of carrying such tools as a country life had taught me to regard as an irreducible minimum to secure the comforts of life at home, and be independent of the assistance of artisans except on great occasions. Many a time these instruments were of signal service in mending a broken hammock or saddle in the bush, or repairing a leaky bath, or the mainspring of a watch, or gramophone, or even in constructing something entirely new from improvised materials when the necessity arose. It was therefore quite natural to think of making a set of instruments for this emergency, the only serious difficulty being the question of raw or improvised material. At this juncture I had recourse to the assistance of my friend Captain Henry, of the West African Frontier Force, who was then in

command of the troops. He was making his evening tour of the lines, and, on being asked what old metal in his armoury he had likely to be of service, he made a minute search, and I regretted to find everything in such perfect order that the only thing he could produce as "unserviceable" was a piece of very hard steel rod about a quarter of an inch in diameter, which had been part of a Maxim-gun extractor. The armourer was not on duty, so I took away the metal almost convinced that the last ray of hope was now extinct.

Outside the door of my mud hut I stumbled on an empty "sparklet" bulb C size, and picking it up, saw in it the outline of a serviceable curette. Everything was plain sailing after that. The sun was approaching the horizon, but I set to work in good spirits, and soon fitted the bulb to the steel rod, making them fast by drilling through the neck of the bulb and the steel rod which was adamant, and riveting the two together with part of a French nail got out of the lid of a packing case. The sun set and the stable lantern was brought in. Its wire handle seemed full of promise, and was easily detached, straightened out, filed down at one end into a fine sharp point, and finally rebent into the shape of a somewhat unorthodox but thoroughly useful tenaculum, to replace the more elegant vulsellum used in such cases. A Sim's speculum was the next desideratum, and a real double-ended one was evolved from what had once been a biscuit tin. It may have been rude, but at all events its angularities were all beaten off and carefully smoothed with emery paper, while rigidity was secured by judicious soldering. A "Primus" stove here proved invaluable in heating the plumber's bolt. The emergency was not so very urgent as to forbid the furnishing of a flexible uterine sound of approved style, so this was made from three strands of copper wire twisted together, soldered for greater security, and graduated in the conventional manner.

Nature now demanded sleep, and daylight was necessary for further search afield to secure wood for the handle of the curette and provide dilators, which were to be made of wood also. A start was made early next morning, and the dilators were made from branches of requisite thickness cut from a hardwood tree. It was thought that these would not swell much or alter in shape during the process of sterilization. This proved correct, and the complete set of double-ended Hegar's dilators was soon ready. The handle of the curette was made of soft wood from a baobab tree, which happens to be one of the few soft woods in that region, and is quite a feature of the landscape, from its immense size and remarkable shape.

The instruments being now all ready and sterilized, an anaesthetist had to be found, "and hastening slowly" to make more sure of success, one had the good fortune to secure the services of Captain Henry, who again came gallantly to the rescue, and proved as good as an expert on that occasion. The only other assistant was one Adamu Wongara, seconded for hospital duties from the Company, whose virtues had blossomed some time previously, first having come to notice when I was put out of action by illness, and on recovering discovered that he had silently imbibed the principles of wound dressing, without any attempt ever having been made seriously to teach him. His previously recognized value, which recommended him for hospital duties, was his capacity as an interpreter, for he could speak seven languages.

The operation was successful, and I had news about a year later that the patient's next pregnancy was happily consummated by the birth of a son, who must now be about ten years old. The original curette and copies of all the other instruments are to be seen in the Wellcome Museum of Medical History in London. I have gratefully to acknowledge the kind permission of the Under Secretary of State for the Colonies to publish this note, and likewise of the Commissioner of Medical Services, Ministry of Pensions, West Midland Region.—I am, etc.,

Birmingham, March 21st.

ALEX. LUNDIE.

JOHN EVELYN AND MEDICINE.

SIR,—It is refreshing to notice that some of your readers are able to find time from the cares of panel practice to dip into John Evelyn's *Diary*. There was a reference recently in your pages to the conversation he

had on December 4th, 1651, with the Duke of York, who affirmed of a woman who swallowed a whole ear of barley, which worked out at her side. The diarist, under date March 24th, 1671, mentions another item of medical interest:

"I saw the chyrurgeon cut off ye leg of a wounded sailor, the stout and gallant man enduring it with incredible patience, without being bound to his chaire as usual on such painful occasions. I had hardly courage enough to be present. Not being cut off high enough; the gangreen prevailed, and the second operation cost the poor creature his life."

It is to be hoped there are many lovers of Evelyn in the medical profession. His courage and humanity in caring for the wounded and sick sailors committed to his charge are astonishing in that indifferent age.—I am, etc.,

Falkirk, April 11th.

GEORGE C. STEWART.

PROSTATIC SYMPTOMS AND THEIR CAUSES.

SIR,—Being an early sufferer myself, I have read with much interest the correspondence on prostatic symptoms, especially the letter from "Senectus." I have exactly the same symptoms he has described—namely, frequency of micturition, sudden urgency, stream small, hesitancy in starting, and in addition I also get priapism at night, subsiding when the bladder is emptied. "Senectus" states that he is much better since he took certain measures. I, and I am sure others, would be grateful if he would state these measures in detail.

As regards causes, for some time I was wrongly fitted with presbyopic glasses, and my bladder symptoms have improved since correct glasses have been given. Even now I think my bladder symptoms are worse when I have to read and write much in the evening by artificial light. It seems to me as if errors of refraction, not properly corrected, and eye-strain, may be aggravating causes.—I am, etc.,

April 11th.

F.T. 53.

THE HARLEQUIN FOETUS.

SIR,—The interesting notes and photographs of this rare condition recently published in the *JOURNAL* remind me that the harlequin foetus has hitherto been one of the riddles of pathology. The following theory may, however, be of service in solving the problem.

The harlequin foetus is atavistic. Its curious collodion-like envelope is due to the persistence of the epitrichium, a membrane which, it will be remembered, normally clothes the embryo from the middle of the third to the beginning of the eighth month of intrauterine life. At eight months this layer breaks down and mingles with the sebium to form the vernix caseosa, and in premature children can often be recognized as desquamating, crinkly wisps loosely adherent to the infant's body. Its function is mechanically protective, preventing maceration in the liquor amnii by swaddling the foetus in a cornified waterproofsheet. It is generally displaced by the hair and sebium accumulating beneath it, the sebium eventually usurping its waterproof function. Complete persistence of the envelope causes harlequin foetus, partial persistence means ichthyosis.

Now a persistent epitrichium is normal to many animals, especially to those whose aquatic habits predispose to maceration of the epidermis—frogs and salamanders, for example. Even among mammals (sloth, certain hogs, probably horses also) it persists till birth, while in cats, bears, sheep, oxen, and deer it is only partially shed. Toldt has recorded a fox with dermal scales; Leibreich (Dissert., Halle, 1853) has described a calf with "foetal ichthyosis." So strong, indeed, is this tendency to retain the epitrichium that its occasional occurrence in man is only to be expected.

This theory not only explains the covering of the harlequin foetus, but also the irregular cracks and fissures which traverse it. Due to torsion and suggesting the irregular cuticular exfoliation periodically occurring in lizards. It explains also the uniformly negative *post-mortem* results; This is not surprising, for there has probably never been anything to find, the fault being purely local, involving the skin only. The commoner atavisms are always with us—cleft palate (persistent buccal vault of amphibia), hare-lip

(persistent oral cleft of selachian fishes), hypo- and epispadias (persistent reptilian urethra). To these is now added that riddle of dermatology—the harlequin foetus.—I am, etc.,

Manchester, April 13th.

GRAHAM RENSUAW.

BREECH PRESENTATION WITH EXTENDED ARMS.

SIR,—Having read with interest the recent correspondence in the JOURNAL on "Breech presentation with extended legs," it has occurred to me that the following case might be of interest to some of your readers:

At 8 a.m. on April 16th, 1921, I was sent for by a nurse to a case of transverse presentation. The patient, aged 39, was a tall, stout woman, eight and a half months pregnant. She informed me that she had only been pregnant once before, fourteen years ago, when labour was normal in every respect. On examining the abdomen it seemed to me that, although I could not locate the foetal head owing to the large amount of adipose tissue present, the long axis of the child was certainly lying in the axis of the uterus. I was therefore surprised to find on vaginal examination the left hand of the foetus presenting in an os the size of a shilling. There was no doubt about it being a hand. I felt it distinctly grip my index finger, and the nurse had also felt it—hence her diagnosis. The presenting part was so high up that I was unable to identify any other part of the foetus without passing the whole of my hand into the vagina. As the pains were not frequent, I left the patient until 12 noon, when, as only slight progress had been made, I arranged with a colleague to give an anaesthetic at 2.30 p.m., so that I could examine more thoroughly. However, at 1 p.m. the child was born without assistance, the breech being delivered first with both arms extended down the sides of the trunk, the thighs and knees being flexed.

The mother was very big; the pelvis was very roomy and the child was very small, 4½ lb., so I suppose that these three circumstances combined to cause delivery in this uncommon position. I confess that after my vaginal examination I was inclined to agree with the nurse, and thought that delivery would have to be carried out by internal version.—I am, etc.,

H. GOOCH, M.B., B.S. Lond.

Drentwood, Essex, April 18th.

Obituary.

HENRY BARNES, O.B.E., LL.D. MCGILL, M.D., F.R.S.E.,
Consulting Physician to the Cumberland Infirmary, and
ex-President of the British Medical Association.

THE death on April 11th, at his house in Carlisle, of Dr. Henry Barnes was briefly announced in our last issue. He was born in 1842 near Wigton in Cumberland, and his life was a long record of distinguished service to his profession and in public life. He graduated with honours at the University of Edinburgh in 1864, and settled in Carlisle in 1866; his first public appointment was that of physician to the Carlisle Dispensary, which he held until, in 1873, he was appointed honorary physician to the Cumberland Infirmary. Other appointments and honours too numerous to mention in detail included the presidency of the British Medical Association in 1896, and at the termination of his year of office he was elected vice-president. Perhaps his almost life-long association with the Cumberland Infirmary as physician, member of and chairman of committee, and finally as its president was the chief element in his fine reputation for energy and single-minded devotion. The writer of these few notes of appreciation, inspired by a long and grateful recognition of Dr. Barnes's services, finds it far from easy to speak in moderate terms of his achievements for this institution. His untiring and unswerving devotion for nearly fifty years to the general and financial advancement of the hospital will live perpetually in the minds of his friends, and fellow-townsmen. Dr. Barnes was freely expended in collecting funds for the improvement of the building, and his unflinching charm and kindness of manner, coupled with sound common sense, made him beloved and respected by all with whom he came in contact. Of his work during the war as honorary secretary and treasurer to the Cumberland branch of the British Red Cross Society, which he had been largely instrumental in establishing, it is impossible to speak too gratefully. His unostentatious and quiet manner and unfailing tact at all times marked him as a discerning administrator. It was a matter of pride to his fellow

workers that his services should have been recognized in the bestowal by the King of the O.B.E.

Dr. Barnes's public-spiritedness also found scope in his work as magistrate for Cumberland; he was called to the bench in 1889, and was chairman of the Cumberland Ward Justices from 1904. Dr. Barnes was no mean antiquarian and archaeologist; his antiquarian researches were greatly concerned with the Roman Wall of Hadrian. His presidential address to the British Medical Association, "The medical history of Carlisle," together with numerous other writings on medical and archaeological subjects, contain much of historical interest generally and locally. His contributions to scientific literature comprised papers on Roman medicine and practitioners, Roman medical inscriptions in Britain.

Dr. Barnes's retirement from practice by no means curtailed his efforts for the public good; he was of too earnest and sympathetic a heart for his grasp of affairs to slacken, and the time thus gained he unsparingly devoted to the various institutions of whose administrative bodies he was member. In Carlisle, where his life's work was done, and throughout Cumberland his name will ever be pronounced with respect and affection, and his personality sympathetically remembered and honoured as one whose gifts have truly served his country.

His interest in the British Medical Association was lifelong, and he was a member of its central council from 1868 to 1900. He was a Fellow of the Royal Society of Edinburgh, and received the honorary degree of LL.D. from the McGill University when he visited Montreal as retiring President in 1897.

Dr. Barnes married in 1873 Miss Emily Mary Barnes, and is survived by his wife and a son and daughter.

The funeral took place on April 15th; the mourners, in addition to members of the family, included many members of the medical profession in Carlisle, Cumberland, and the Border counties. Dr. Livingstone of Dumfries represented the British Medical Association and the Border Counties Branch. The city officials also attended, and the Mayor, speaking for the Bench afterwards, said that during the thirty-four years Dr. Barnes was a magistrate he had been a constant attender at the court, and his judgement and advice were highly valued. A tribute to his memory was paid also by Mr. John Graham on behalf of the solicitors practising in the courts.

SURGEON-LIEUT.-COLONEL L. MANCHÉ, M.D.,
Malta.

SURGEON-LIEUT.-COLONEL L. MANCHÉ, M.D., late of the Royal Malta Artillery, died at Valletta, Malta, on February 16th, at the age of 75 years. The late Colonel Manché had been the founder of the Malta and Mediterranean Branch of the British Medical Association, and acted as Honorary Secretary from its formation in 1888 to 1902. He was several times President of the Branch, and at the time of his death he was Vice-President both of the Malta Branch of the Association and of the Malta Medical Association. Up till the end of his life he maintained the keen interest he had always shown in the organization of the local medical body, and in bringing together the naval, military, and civil members of the profession on the island, amongst all of whom he was deservedly popular.

Colonel Manché was the first holder of the Chair of Ophthalmology in the Malta University, and he performed pioneer work in developing the teaching and the practice of the speciality. He established and maintained at his own expense an ophthalmic clinic for poor patients. His great professional ability, his unselfish interest in all matters that affected the welfare of the medical profession and of the general public, and his courteous and charitable disposition were greatly appreciated by all sections of the community, and his death has caused the most widespread regret.

THE LATE DR. PETER DUNCAN OF CROYDON.
Sir Thomas Barlow, Bt., writes: Peter Duncan was a first-rate student, alert, accurate and thorough in both theory and practice. The same qualities characterized his career as a singularly well-informed and thoroughly equipped practitioner. It was the rarest thing in a consultation for Duncan to have missed anything, and if he had pride in his professional work it was that he took cognizance of the whole man. He never spared himself in

his solicitude for the welfare of his patients, and they loved and appreciated it. Duncan was a loyal colleague and a staunch friend. He never "wore his heart on his sleeve," and, indeed, he had a certain reserve; but now and again his friends were struck by the evidences in quiet ways of his keen and abiding remembrance and of his warm regard. *Requiescat in pace!*

Dr. Percy J. Duncan writes: In your appreciative memoir of the late Dr. Peter Thomas Duncan you have written that he was a cousin of the late Dr. Matthews Duncan. May I correct that statement and add that the family was an Irish one dwelling in the neighbourhood of Killyenny. Three sons became members of the medical profession in London—Dr. William Duncan, Dr. Peter Charles Duncan, and Dr. B. Archdekin Duncan—and the subject of your memoir and his younger brother, Dr. William Duncan, were the sons of the first named. There is a cousin still in Ireland, the Rev. Peter Charles Duncan of Kildonagh, the son of the eldest brother of the family. The writer is the second son of the Dr. Peter Charles Duncan referred to above.

Dr. THOMAS LETTIS of Great Yarmouth died on April 9th as the result of injuries sustained three days before, when he was knocked down by a motor car while endeavouring to board a tramcar. Dr. Lettis, who was a member of an old Yarmouth family, was born in 1845. He received his medical education at University College Hospital, and took the diplomas of M.R.C.S. in 1866 and L.S.A. in 1877, graduating M.D. Dub. in 1899. After holding the post of assistant house surgeon at University College Hospital he returned to his native town to practise. At the time of his death he was consulting honorary medical officer to the Great Yarmouth Hospital and a member of the Great Yarmouth Division of the British Medical Association.

Dr. ARTHUR DRNISON died at Burley, Leeds, on April 6th, aged 52. He was educated at Edinburgh, where, after taking the Scottish triple qualification in 1891, he graduated M.B. and Ch.B. in 1893, and M.D. in 1895. He then went into practice at Burley, Leeds, where he was medical officer and public vaccinator to No. 4 district of the Leeds Union. He took a temporary commission as lieutenant in the R.A.M.C. on October 15th, 1915, and was promoted to captain after a year's service. He saw service in Malta and Salonica as sanitary section staff captain; at the former place illness necessitated his admission to a tuberculosis sanatorium, from whence he only returned to England last Christmas. He took great interest in local affairs, and was the representative of the West Ward on the Leeds City Council for nine years, prior to which he also represented the Headingley Ward on the same body. He was also a former chairman of the corporation sanitary committee. The funeral, which took place on April 9th, was attended by many friends, including members of the health staffs of the Leeds corporation.

The Services.

INDIAN MEDICAL SERVICE.

CIVIL EMPLOYMENT PAY.

The following communiqué has been received from the India Office. It is not dated, but was sent to us on April 18th:

1 With effect from January 1st, 1920, the new scales of pay for officers of the Indian Medical Service in civil employment are as follows:

(a) The rates of pay for officers of the Indian Medical Service in civil employment, who hold one of the following appointments, are as specified below:

Director General, Indian Medical Service, Rs 3,500.
Surgeons-General Rs 3,000
Inspectors General of Civil Hospitals, Rs 2,750.
Sanitary Commissioner with the Government of India, Rs 2,500.
Inspectors-General of Prisons, Rs 2,300, rising by annual increment, of Rs 50 to Rs 2,500
Sanitary Commissioners, Bengal, Bihar, and Orissa, United Provinces, Panjab, Madras, Burma, Bombay, and Central Provinces, Rs 2,100, rising by annual increments of Rs. 60 to Rs. 2,400.
Sanitary Commissioner, Assam, Rs 1,950, rising by annual increments of Rs. 50 to Rs 2,300
Principal, Medical College, Calcutta, Rs 2,350
Superintendent, Campbell Medical School, Calcutta, Rs 2,350 for a Sec Surgeon
Surgeon Superintendent, St George's Hospital, Bombay, Rs 2,350.
Superintendent, General Hospital, Rangoon, Rs 2,150.

(b) The rates of pay of officers, of the Indian Medical Service in civil employment, who do not hold any of the appointments specified in the other clauses of this paragraph, are shown in the following statement:

(1) Rank and Service	(2)	(3) Pay (Rs per Month)	(4) Overseas Pay (Rs per Month)	(5) Total Pay (Rs per Month)
Lieutenant		500	150	650
Captain:				
(i) During the first 3 years' service as Captain		650	150	800
(ii) With more than 3 and less than 6 years' service as Captain		750	200	950
(iii) With more than 6 years' service as Captain		850	200	1,050
Major:				
(i) During the first 3 years' service as Major		950	250	1,200
(ii) With more than 3 and less than 6 years' service as Major		1,100	250	1,350
(iii) With more than 6 years' service as Major		1,250	250	1,500
Lieutenant Colonel:				
(i) Until completion of 25 years' total service		1,500	250	1,750
(ii) During the 25th and 26th years of service		1,600	250	1,850
(iii) After completion of 25 years' total service		1,700	250	1,950
(iv) When selected for increased pay		1,750	250	2,000

(c) The rates of pay in columns (3) and (5) of the statement in clause (b) are increased by Rs. 250 a month for all officers of the Indian Medical Service who hold one of the following appointments:

(i) Professorial, Panjab, United Provinces, or Medical College; (ii) Professor of Medicine in Government Medical College; (iii) appointments in the Examiners; (iv) Deputy Officers at Bombay, Calcutta, and Madras; (v) all Principal Medical Officers; (vi) Deputy Director-General, Indian Medical Service; (vii) Assistant Director-General, Indian Medical Service (Sanitary) and (Stores); (viii) Surgeon to his Majesty the Viceroy; (ix) Police Surgeon, Rangoon; (x) Superintendent, Central Lunatic Asylum; (xi) Superintendent, Army Institute; (xii) Superintendent, Royal Botanical Garden, Calcutta.

(d) The rates of pay in columns (3) and (5) of the statement in clause (b) are increased by Rs. 200 a month for all officers of the Indian Medical Service who hold one of the following appointments:

(i) First and Second Class Surgeons, General Hospital, Calcutta; (ii) Surgeons, General Hospital, Bombay; (iii) Surgeons, General Hospital, Madras, and Bengal.

(e) For Superintendents of 1st class Central Gaols and the second Medical Officer, Port Blair, the rates of pay in columns (3) and (5) of the statement in clause (b) are increased by Rs. 150 a month.

(f) For Personal Assistants to Surgeons General the rates of pay in columns (3) and (5) of the statement in clause (b) are increased by Rs. 100 a month.

(g) For Superintendents, 2nd class Central Gaols, the rates of pay in columns (3) and (5) of the statement in clause (b) are increased by Rs. 50 a month.

(h) In addition to the above rates of pay, officers of the Indian Medical Service who hold one of the following appointments draw in addition the duty allowances mentioned:

(i) Officers of the Bacteriological Department who are Directors of 1st class Central and Provincial Laboratories, Rs. 200 a month; (ii) Officers of the Bacteriological Department, who are Directors of Pasteur Institutes, Rs. 100 a month; (iii) Deputy Director General, Indian Medical Service, Rs. 400 a month, subject to a maximum of Rs. 2,500 a month for the total pay and duty allowance combined; (iv) Assistant Directors General, Indian Medical Service (Sanitary) and (Stores), Rs. 250 a month, subject to a maximum of Rs. 2,500 a month for the total pay and duty allowance combined.

Note.—The appointment of Additional Assistant Director-General, Indian Medical Service will, for the present, continue to grade for the purposes of pay as a Deputy Assistant Director, Medical Services, Army Headquarters.

2. The rates of overseas pay specified in paragraph 1, clause (b), apply only to the officers of the Indian Medical Service in civil employment who fall under paragraph 1, clauses (b) to (h). This overseas pay will be drawn by all such officers who were in permanent service on the 1st December, 1918, and by all such British officers who have joined or may join the service after that date. Such Indian officers who have joined or may join the permanent service after the 1st December, 1918, will not be allowed to draw this overseas pay, unless they are already drawing pay at a higher rate than is admissible without overseas pay, in which case they will continue to enjoy the benefit of that high rate for so long as they would otherwise have done; but they will not receive any further increment until it is due to them under the scales now sanctioned.

3. Exchange compensation allowance is withdrawn with effect from the 1st January, 1920.

4. In bringing officers at present in service on to the revised rates of pay, Articles 156 to 158 of the Civil Service Regulations

will not apply. A personal allowance is, however, sanctioned for all existing incumbents of offices who are drawing a salary greater than that admissible under the scales now sanctioned, so as to bring their emoluments up to the amount now enjoyed. These personal allowances will be absorbed as increments are earned.

5. Subject to the provision in paragraph 4 the initial pay of the scales now sanctioned in the case of an officer who holds an appointment on a time-scale of pay specified in paragraph 1, clause (a), will be regulated according to the number of years he has held the appointment permanently, and the broken period of a year of service, which such an officer has put in before January 1st, 1920, will remain at his credit for the next increment.

Note.—The rates of pay in paragraph 1, clause (b), apply to all appointments held by officers of the Indian Medical Service in civil employ, which are not specified in the remaining clauses of that paragraph. These include, amongst others, the following appointments:—Civil Surgeons; Agency Surgeons; Presidency Surgeons, 1st and 2nd Districts, Bombay; Police Surgeon, Calcutta; Senior Surgeon and ex officio Sanitary Commissioner, Mysore; Medical Officer, Kathiawar, Political Agent, General Hospital, Rangoon; Medical Officer, General Department, Bikanir; Medical Officer, Mowar But Corps, Kherwar; Superintendent of Mahabeshwar; Superintendent of Mathuran; Resident Surgeon, Medical College, Calcutta; Resident Physician, Medical College, Calcutta; Resident Surgeon, Eden Hospital, Calcutta; Resident Medical Officer, General Hospital, Madras; and Assistant Superintendent, Government Maternity Hospital, Madras.

ROYAL AIR FORCE NURSING SERVICE.

REGULATIONS regarding conditions of service in the Royal Air Force Nursing Service, which was established by Royal Warrant on January 27th, 1921, have now been issued by the Air Ministry. The service consists of a matron-in-chief, matrons, senior sisters, sisters, and staff nurses. Candidates are required to join as staff nurses, and appointments, which are subject to a probationary period of six months, are given to approved persons of British parentage, over 25 and under 35 years of age, who possess a certificate of training for at least three years at a large civil hospital in the United Kingdom. Full particulars of the service and forms of application for appointment may be obtained from the Matron-in-Chief, Air Ministry, Kingsway, London, W.C.2.

DEATHS IN THE SERVICES.

Deputy Surgeon-General Oliver Codrington, R.A.M.C.(ret.), who died recently at the age of 82, was educated at the London Hospital, and took the M.R.C.S. in 1858, the L.S.A. in 1859, and the M.D. of St. Andrews twenty years later, in 1878. Entering the army as assistant surgeon on June 13th, 1859, he became brigade surgeon on August 19th, 1885, and retired, with a step of honorary rank, on March 27th, 1886. He served in the New Zealand war of 1864-66, receiving the medal.

Major John FitzGerald Burke, R.A.M.C.(ret.), died recently at Pembroke. He was born at New Quay, County Clare, on June 14th, 1857, took the L.R.C.P. and S. Edin. in 1882, and entered the army as surgeon on August 1st, 1885, attaining the rank of major after twelve years' service, and retired on October 29th, 1902. After his retirement he was employed at Lancaster from 1902 to 1911, and subsequently at Penally; and also during the recent war. He had a long list of war service. He served as a civil surgeon in the Egyptian war of 1882, before entering the army, receiving the medal with the Khedive's bronze star; Burma, 1885-87, medal with clasp; Ashanti, 1895-96, star; West Africa, Lagos, 1897-98, Sierra Leone, 1898-99; Protectorate Expedition, medal with clasp; and South Africa, 1900, Queen's medal with clasp.

Major William Barbour A. K. Cullen, I.M.S., died of pneumonia at Meerut on March 29th. He was the younger son of the late Deputy Surgeon-General Cullen, A.M.S., born on March 11th, 1881, and was educated at Edinburgh, where he graduated M.B. and Ch.B. in 1903. After filling the posts of assistant house-surgeon at the Chesterfield Hospital and at the County Hospital, Taunton, he entered the I.M.S. as lieutenant on February 1st, 1906, attaining the rank of major on August 1st, 1917. He had a varied experience of the different theatres of war in the past seven years, accompanied the original Indian force to Europe in November, 1914, and served in France and Belgium till November, 1915; in Mesopotamia from December, 1915, to March, 1916; in the Mahsud operations on the North-West frontier of India from May to August, 1917; with the Egyptian expeditionary force in June and July, 1918; and with the Aden field force from July to October, 1918; and was mentioned in dispatches in the *London Gazette* of June 15th, 1916.

Captain Robert Scott Cumming, R.A.M.C., S.R., died in the 3rd British General Hospital at Basra on March 14th. He was the eldest son of the late Robert Cumming, advocate, of Aberdeen, and was educated at the university in that city, where he graduated M.B. and Ch.B. in 1915. Immediately afterwards he took a commission as lieutenant in the Special Reserve of the R.A.M.C. on July 24th, 1915, and was promoted to captain after six months' service. He received the Military Cross on July 26th, 1917.

The King of the Belgians has conferred the decoration of Officer of the Order of the Crown of Belgium upon Wing-Commander Lewis Leister Greig, M.V.O., M.B., R.A.F., in recognition of valuable services rendered in connexion with the war.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY council was held on April 14th, when Sir Anthony Bowlby, President, was in the chair.

The following prizes were awarded: *Jacksonian Prize*: to Mr. Harold Burrows (Southsea) for his essay on the results and treatment of gunshot injuries of the blood vessels. *John Tomes Prize*: to Dr. James Sim Wallace for his work in connexion with the prevention of dental caries. *Cartwright Medal and Prize*: to Mr. W. Kelsey Fry, M.C. (Guy's Hospital), for his essay on the treatment of injuries of the jaws, and the restoration by mechanical means of parts of the jaws lost as the result of injury or removal on account of disease.

The subject selected for the Jacksonian prize for the year 1921 is the effects produced by radium upon living tissues, with special reference to its use in the treatment of malignant disease.

The subject for the next Cartwright prize for 1921-25 is: Variations in the form of the jaws, with special reference to their etiology and their relation to the occlusion of the dental arches.

Mr. Kenneth Owen Parsons was appointed Bigley student for the ensuing three years.

Professor Charles Scott Sherrington, P.R.S., and Sir S. Squire Sprigge, members of twenty years' standing, were elected to the Fellowship.

Mr. Raymond Johnson was elected to represent the College in the University of London.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—*Medicine*: A. Shakur, J. L. Lloyd-Jones, V. H. L. Anthonisz, W. B. Stott, W. Campbell, R. N. Nanda, A. Y. Khan. *Surgery*: J. S. A. Rogers, O. P. Fox, W. D. Stott, R. N. Nan. *Obstetrics*: A. Shakur, J. L. Lloyd-Jones, J. R. Williams. *Medical Jurisprudence*: J. S. A. Rogers, O. P. Fox, W. D. Stott, M. S. Hassen, P. G. Bainbridge, D. R. Nicol, J. L. Lloyd-Jones, Rachel Caplan.

The following, having passed the Final Examination, were admitted L.R.C.P.E., L.R.C.S.E., L.F.P.S.Glas.:

Helen Worthington, D. R. Olliers, N. M. D. Fox, D. J. H. Ferdinando, J. Murray, A. J. Vakil, A. A. Hamilton, A. R. Taylor, R. E. Hopton, J. I. Coventry, R. G. Clouston, P. F. Fairley, S. D. de Vos, B. S. Jain, F. X. H. Hayes, J. J. L. McDonald, F. L. A. Gaco, G. H. Thomas, K. A. Doodhar.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have passed the examination of the school at the termination of the sixty-fifth session, January-April, 1921:

*C. T. Maitland (Duncan Medal), *H. R. S. Richards, *A. Crawford, *Miss M. M. Ross, *R. G. Simpson, *J. O. Beven, *W. M. Howells, J. M. Wallace, J. Segal, O. M. Banbury, D. N. Gole, P. Parthasarathy, M. Morrison, L. M. Sen, B. K. Ray, J. C. Rowan, H. Smith, Miss A. Shaw, D. S. Scott, R. A. W. Procter, Miss A. M. Mackay, J. C. Coetzee, K. A. Gandhi, C. L. Bahni, N. S. Ketwall, F. X. Costello, K. C. Chong, S. Miller, Surgeon Lieut. Commander P. N. Button, Miss M. Jervis, A. R. McLean, Miss L. J. Murphy, A. R. Jennings, Miss M. J. Ahern.

* With distinction.

Medical News.

THE King has been pleased, on the recommendation of the Home Secretary, to appoint Dr. Sidney Reginald Dyer, Medical Inspector of Prisons, to be a Commissioner of Prisons. Dr. Dyer was formerly medical officer of H.M. Prisons, Stafford, Wandsworth, and Buxton, and was called to the Bar at the Middle Temple in 1896.

THE Prince of Wales (President of the hospital) will take the chair at the annual meeting of the Court of Governors of the Hospital for Sick Children, Great Ormond Street, on Tuesday, May 3rd, at 4 p.m.

THE Minister of Pensions has appointed Dr. A. E. Knight, Commissioner of Medical Services, to hold the combined post of Regional Director and Commissioner of Medical Services in the Ulster Region of the Ministry.

A PARLIAMENTARY White Paper issued recently states that the total receipts paid into the motor taxation account by the local authorities down to March 7th was a little over seven million sterling. The number of cars taxed on horse-power, which would include all ordinary private and professional cars, was 202,000, and the yield was £2,810,800. Commercial cars and lorries yielded half a million less. Motor cycles numbered 185,000, and yielded £488,600. There were two hundred mechanically driven bath chairs, yielding £50 in taxes. It appears that nearly all the licences taken out are for the whole year. The reply to a question in the House of Commons shows that by the end of March the total receipts had increased to seven million and three-quarters.

A SPECIAL meeting of the Fellows of the Royal Society of Medicine will be held on Monday next, at 5 p.m., to consider a recommendation of the Council that the subscription of all Fellows in the London postal area should be raised to five guineas and that for Fellows residing elsewhere in the United Kingdom to four guineas. In addition it has been arranged to reduce the cost of the *Proceedings* by using cheaper paper and smaller type. It is proposed that the subscription paid by Fellows living abroad shall remain three guineas.

MR. ARTHUR CHEATLE will give a lantern demonstration on "The cellular development in the temporal bone" at the opening of the summer session of the Central London Throat and Ear Hospital, Gray's Inn Road, on Wednesday, May 4th, at 4 p.m.

THE fifth annual celebration of National Baby Week will be held from July 1st to 7th, 1921. The chairman of the executive committee is Dr. Eric Pritchard; the honorary secretaries are Mrs. H. B. Irving and Mrs. Sloan Chesher, M.D., and the secretary Miss M. S. Gray. The office is at 5, Tavistock Square, W.C.1.

As the Industrial Welfare Society receives continual requests from firms for definite aid in the application of the principle of industrial welfare to their particular needs, the society has organized itself for this purpose. In addition to the headquarters staff in London and the local branches under the direction of district organizers, a working arrangement in regard to special subjects bearing upon industrial welfare has been made with the appropriate societies and experts both in this country and abroad. The headquarters staff is available for the discussion of conditions and the suggestion of schemes of industrial welfare for different industries, and it sends speakers to address gatherings on subjects kindred to its object. It will assume complete responsibility for the carrying out of welfare schemes, or it will recommend qualified directors. The society also advises on general health problems affecting various industries, and on the establishment of holiday and convalescent centres in industrial districts. There is little doubt that this propaganda work is best carried on by a voluntary society rather than it should be cramped by the rules and regulations within which a Government department would have to work. The offices of the Industrial Welfare Society are at 51, Palace Street, London, S.W.

AN English-speaking conference on infant welfare will be held, under the auspices of the National Association for the Prevention of Infant Mortality and National Baby Week Council, at the Kingsway Hall, London, on July 5th, 6th, and 7th, with Viscount Astor as president. The chief subjects under discussion will be: residential provision for mothers and babies; inheritance and environment as factors in racial health; and the supply of milk, its physiological and economic aspects.

THE annual meeting of the Medical Mission Auxiliary of the Church Missionary Society will be held in the Queen's Hall, Langham Place, London, W.1, on Wednesday, May 4th, when the chair will be taken by Colonel A. Carless, C.B.E., M.S., at 7 p.m.

THE National League for Health, Maternity, and Child Welfare has just issued its report for the year 1920. This League is a federation of ten different societies which deal with various aspects of the questions included in the title. From the report it is evident that a great deal of work is being carried out in every part of the country by the different sections of the League, and by the co-operation of these sections overlapping of the activities is prevented. During the past year five maternity hostels and twenty-six ante-natal clinics have been established by the aid of the League, and under its auspices are carried on a babies' hotel and nursery training school at Stoke Newington, a convalescent home for mothers and babies at Shooters Hill, and a holiday home, formerly at Henley and now to be re-established at Maidenhead.

AT the meeting of the Société française d'oto-rhino-laryngologie in Paris, on May 9th, Drs. Moore and Hautant will read a paper on the radiotherapy of malignant tumours in oto-rhino-laryngology, and Dr. Lemaitre will discuss the orbito-ocular complication of sinusitis.

A MEETING of the Society of German Laryngologists and of the German Otological Society will be held at Nuremberg on May 12th to 14th, under the presidency of Dr. Boenninghaus and Dr. Rudolf Panse of Dresden, when the organization of a school otological service will be discussed.

THE Vienna Medical Society has elected Dr. Ferrière of Geneva and Mr. Hoover of Washington honorary members in recognition of their services to Austria.

DR. EDWARD WALFORD, who has resigned the post of medical officer of health for the city of Cardiff, has been granted by the city council a pension of £500 per annum. Dr. Walford has been M.O.H. of Cardiff since 1888, and as his predecessor, Dr. Paine, held office from 1847 until his appointment, Cardiff must be one of the very few cities in this country—if not the only one—in which only two medical officers of health have held office.

The Conjoint Board of Scientific Societies has decided to discontinue the publication of the Annual Calendar and Fortnightly Bulletin of Scientific Meetings (Diary of Scientific and Technical Societies) owing to the heavy printing liabilities incurred.

THE mortality of illegitimate infants in 1919 in England and Wales was a little over twice as great as of the legitimate. It was particularly heavy from gastrointestinal disorders. The Affiliation Orders Act of 1914 permitted the appointment of a collecting officer, whose duty it is to see that the mother of an illegitimate child receives an adequate sum for its maintenance from the father. The Bastardy Bill, which it is hoped may be reached in the House of Commons on Friday next, April 29th, would make the clerk to the justices (or the chief clerk of a metropolitan police court) the collecting officer, but would permit him to delegate his powers. The bill would raise the maximum contribution from the putative father from 10s. weekly to 40s.; it would also legitimize a child born out of wedlock if the parents subsequently intermarried. The bill as originally drafted was a very much more ambitious measure: as it now stands, and regarding it only from the public health point of view, we consider that it deserves support. Its most important point is the power it would give to the magistrates to increase the weekly allowance. The high mortality among illegitimate infants is probably in the main due to the fact that the mother must put it out to nurse either altogether or during the day in order to earn a living.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS for inclusion for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 423, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 423, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR OF THE BRITISH MEDICAL JOURNAL, *Attilage*, Westrand, London; telephone 2630, Gerrard.
2. FINANCIAL MANAGER (Advertisements), 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin; telephone, 4737, Dublin, and of 1 Square, Edinburgh (telegrams: ne. 4361, Central).

QUERIES AND ANSWERS.

WE are asked what steps a V.A.D. nurse, who wishes to train as an assistant in a pathological laboratory, should take.

"MEDICUS" writes: An old patient, who wears an artificial eye, asks how the discoloration and dulling from use can be removed? Would any acid or other chemical effect this without damaging the glass? The makers charge a guinea or more to repolish an artificial eye.

* The repolishing and colouring of an artificial eye is not a piece of work that can be safely undertaken by an amateur. It needs much skill and long practice, with a full knowledge of the complicated art of glass enamelling. The cost of the work indicated in the inquiry is high, and estimates should be sought from some of the larger firms that specialize in this work—for example, Messrs. Halford, 41, Upper TOLLINGTON Place, London, N.4; Messrs. Taylor and Miller, 8, New Oxford Street, London, W.1, or Messrs. Maw, Son and Sons, Aldersgate Street, London, E.C.

INCOME TAX.

"SIMPLICITAS" asks what is the method of dealing with partnership profits.

"The average profits of the practice are ascertained—that is, the gross receipts (or bookings less allowance for bad debts) less the expenses incurred in the working of the practice for the past three years. This "average" sum is assessed on the firm, but the appropriate allowances for the individual partners are deductible therefrom. The tax is payable by the firm in law, but in fact it is usually shared between the partners on the basis of their individual shares, the inspector of taxes supplying the necessary figures on request. Income tax is payable in two instalments—that is, on January 1st and July 1st, in respect of the income for the year ending April 5th, whether that income has been received in cash or not."

"MEDICO" has been carrying on a general practice, and, to a more limited extent, a specialist's practice elsewhere. He has sold his general practice, and proposes to reside near, and devote his whole time to, his specialist's practice. How will he then be assessable?

"On the basis of his past three years' receipts from, and expenses in connexion with, the specialist's practice only. The expense of removal will not be an admissible deduction."

"F. R. I. P. H." asks for advice as to the following car purchases and sales: (1) car A, 12/16 h.p., second hand, bought August, 1919, for £525 and sold for £415; (2) car B, small second-hand car, bought February, 1920, for £220, and still retained; (3) car C, bought August, 1920, 10.5 h.p., new, for £550.

"The difficulty is that the cars are so dissimilar. Assuming that car A (in the condition in which it was bought) would have cost £525 in August, 1920, the amount of deductible expense is £525 less £415 = £110. The purchase of an additional car does not give rise to a claim for expenses, but if cars B and C were sold and a car superior to either were bought our correspondent could then claim that the whole of the net cost could be allowed—that is, the two smaller cars could be reckoned as equivalent to a single new car of higher power or quality."

"A. B. C." inquires whether income tax is payable on "temporary half-pay granted on account of a disability caused by the war."

"Prima facie a "disability pension" is exempt and "half-pay" is chargeable. We should like to be clearer on the facts before giving a categorical reply. Can the Government grant temporary half-pay "on account of a disability"? We suggest that "A. B. C." might ascertain the precise sub-head of the War Office Vote to which the payment is charged. It may, of course, be a disability pension measured in terms of half-pay."

"EXPECTANS" inquires as to the method of dealing with 4 per cent. tax compounded interest on the Government 1929-42 Stock.

"It should not be returned "for assessment," but should be included in any declaration of total income being shown separately and marked "tax compounded." On the figures given by "Expectans," and assuming that he is a married man, the tax payable by him would be as follows:

	£	s.	d.
Earned income, less 10 per cent.	810 0 0
5 per cent. War Loan interest	150 0 0
Assessable income	950 0 0
Deduct personal allowance...	225 0 0
Taxable income	735 0 0
Tax payable—£225 at 3s.	33 15 0
£510 at 6s.	153 0 0
			186 15 0

The income on the 4 per cent. stock is not "taxable," as the tax is compounded.

LETTERS, NOTES, ETC.

THE medical officer of health for the Port of London, Dr. W. M. Willoughby, reports that since the campaign was instituted twenty years ago 1,169,692 rats have been destroyed in the docks and on vessels arriving in the port.

EFFECT OF GUNSHOT WOUND ON SKULL.

"CORONER" writes: The following case may be of interest to your readers, showing the necessity in all cases of a gunshot wound for a post-mortem examination to prove accurately the entrance, and exit of the bullet, and also the effect of cordite powder in not producing scorching or burning at the entrance. A young officer was shot dead in a barrack room, one other

officer being in the room with him. There was on the side of the skull, just behind the left ear, a very small wound which the two surgeons who examined the body in the first instance diagnosed as the entrance wound. In a parallel line across the skull there was a wound behind the right ear, showing bleeding and laceration, and an aperture considerably larger than on the left side. This was diagnosed as the exit wound. If the first diagnosis had been correct, the automatic revolver which had been used must have been held in a straight line behind the left ear—an almost impossible position for a right-handed man. The skull was opened and the bone of the skull very carefully examined; both surgeons were convinced that the first diagnosis was wrong. The evidence from the splintering of the bone, and the way such splinters had been carried into the skull, showed that it was the large wound on the right side which was the entrance wound, and the very small wound on the left side the exit. The next point was that there was no apparent singeing, although the evidence was that the deceased held the revolver close to his head. The revolver was an automatic, carrying a 0.22 cartridge, and the powder was alleged to be cordite. A sheep's head was obtained, and a rabbit's skin tightly stretched over this head. Several shots were fired from the revolver into the head, and it was proved that, firing the revolver two inches from the head, there was no discoloration or scorching of the hair on the rabbit's skin, and the fracture of the bones of the sheep's head, where the bullet passed through, corresponded to that of the bones of the skull of the deceased—namely, a considerable wound, and fracture where the bullet entered, and a very small wound hole where the bullet came out.

The generally accepted theory appears to be that the exit wound is always larger than the entrance. This theory is evidently unreliable, and had it been accepted in the case herein referred to, the other officer in the room would have been charged with murder.

TERMINOLOGICAL CONFUSION.

THE REV. J. O. H. CARTER, M.A. (Slymbridge Rectory, Glos.), writes to suggest that in discussions with regard to venereal disease confusion would be avoided by using "prophylactic" for prevention of disease *ante factum*, that is, before the sexual act, and "metaphylactic" for prevention of disease *post factum*—after the act.

BRITISH OPHTHALMIC HOSPITAL, JERUSALEM.

THE British Ophthalmic Hospital in Jerusalem is a hard working charitable institution which is carried on by the Order of the Hospital of St. John of Jerusalem in England, Lieut.-Colonel J. C. Strathearn being the chief surgeon. Since the war a considerable amount of restoration has had to be done, and extension of the out-patient department is still necessary. The report for 1920 shows, however, that the work of the hospital is now rapidly approaching—and, in some items, such as the number of operations performed, actually surpassing—the average of the years immediately before the war.

A CORRECTION.

DR. J. A. HATFIELD (London) writes: May I correct an error that has crept into print in the advertisement of the lectureship in psychotherapy at Birmingham University? I am there wrongly described as lecturer in psychotherapy at King's College, whereas my position is the more humble one of lecturer in psychology. The error has naturally given rise to some misapprehension.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33, 34, 35, and 36 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 39, 31, and 32.

THE appointment of certifying factory surgeon at Lyncham (Oxford) is vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	22 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postal telegrams letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

476 Pleural Effusions in Artificial Pneumothorax.

DUMAREST and PAPADIMITRIU (*Phil. Journ. Sez. Med.*, January 1st, 1921) point out that the pleural effusions which occur in the course of artificial pneumothorax are not always of a tuberculous nature but may be due to various causes, the nature of which can be determined by cytological and clinical examination. The writers distinguish the following three groups: (1) Idiopathic pleurisy, characterized clinically by its early appearance, absence of constitutional disturbance and complete disappearance without sequelae; cytologically by eosinophilia; and lastly by the scanty albumin content and slight degree of coagulability of the effusion. (2) Tuberculous pleurisy, which is subdivided into (a) a benign form without constitutional disturbance and characterized by a scanty effusion with small albumin content and a cytological formula of large and later small lymphocytes, and (b) a malignant form characterized by constitutional disturbance, a progressively increasing effusion and cytological formula of large and later small lymphocytes without endothelial cells. (3) Septic pleurisy, characterized by an acute course with much constitutional disturbance and a cytological formula of polymorphonuclear leucocytes. Transitional forms may also occur.

477. STAFFMAN and ROSENBLATT (*Am. Journ. of Med. Sciences*, February, 1921) call attention to multiple fluid collections occurring in the chest during artificial pneumothorax. The condition can only be detected by the characteristic fluid levels seen on x-ray examination, when one or more fluid levels are seen superimposed upon and parallel to the main effusion, and a fluid wave can be elicited on each level independently. Among thirty-two cases of hydropneumothorax five presented the condition which appears to be due to sheet-like adhesions spreading hammock-like from the visceral pleura across the pneumothorax area to the chest wall, these act as a receptacle to catch the fluid secreted from the pleural surface above them in position, and also part of the main effusion may become entrapped in them by change of posture. Two or more independent hydropneumothorax pockets may result from attempts to induce pneumothorax at different levels, or a localized spontaneous pneumothorax may occur adjacent to a pocket of artificial hydropneumothorax. The adhesions may be present prior to the induction of the pneumothorax and occasionally they may result from a thickened interlobar septum, or they may be newly formed as a result of organization of the exudate. Five cases are reported (with skiagrams), one due to spontaneous pneumothorax superimposed upon a limited induced pneumothorax, two due to hammock-like adhesions resulting from a pre-existing thickened interlobar septum, and two due to shelf-like adhesions formed by the organization of the exudate.

478 Artificial Pneumothorax in Pulmonary Tuberculosis

RODANO (*Il Polmone*, Sez. Med., January 1st, 1921) records the histories of 27 cases of pulmonary tuberculosis treated by artificial pneumothorax and comes to the conclusion that this method is of undoubted efficacy under certain conditions, which may vary in different cases, a unilateral lesion even when advanced not being a contra-indication. The pleural effusion which frequently occurs during artificial pneumothorax does not usually aggravate the prognosis or delay recovery. If thoracentesis is carried out in such cases with proper precautions, it is not so dangerous as is generally supposed, and sometimes, especially in acute cases, may be of real benefit to the patient. Pleural eclampsia or gas embolism is the most serious complication of artificial pneumothorax, but the symptoms which at first are so alarming may subside without leaving any trace. In lesions of the left lung it is not uncommon for artificial pneumothorax to be followed by erythema mimus which is always systolic in time and may last from a few days to a few months, and may even be accompanied by a distinct systolic thrill. Acute bronchial affections which occur during artificial pneumothorax usually subside rapidly and almost spontaneously without it being necessary to suspend the treatment. It is sufficient in such cases to make the injections at longer intervals. Haemoptysis, which may occur either at the beginning of

treatment or at an advanced stage, is not a contra-indication to artificial pneumothorax, but its treatment varies according to the case and the state of compression of the lung.

479. Effects of Friedmann's Tuberculosis Vaccine

GLASS (*Deut. med. Woch.*, March 3rd, 1921) has collected several cases of tuberculosis treated by Friedmann's vaccine, all of which responded unfavourably, the responses in some cases amounting to disasters. Personally he has seen more than one such disaster, and the following case is particularly instructive, as Friedmann himself administered the vaccine. The patient was a married woman whose pregnancy was interrupted on account of active pulmonary tuberculosis. After the induction of abortion she felt well and was afebrile. An x-ray examination seemed to indicate that this was a suitable case for Friedmann's vaccine, which was accordingly given. A fortnight later she became very ill and developed a hectic type of fever. She was therefore admitted to hospital, where she died about two months later of bilateral caseous pneumonia. Another case was that of a medical man, who developed a tubercle of the hand as a sequel to a necropsy. In spite of Friedmann's vaccine the disease progressed slowly. Half a year later a second very small injection of the vaccine was given, and this was followed by an acute exacerbation of the tubercle. Ultimately the disease cleared up under diathermy. In a third case a moderately severe afebrile type of pulmonary tuberculosis developed into a febrile and rapidly progressive type ten days after an injection; within three months the patient was dead. The author comments on the fact that though Friedmann himself has treated an enormous number of cases with his vaccine, he has not published any disasters similar to those which unprejudiced observers apparently find to be quite common.

480. VAN TILBURG (*Ned. Tijdschr. v. Geneesk.*, March 12th, 1921) reviews the literature of the subject of Friedmann's remedy for tuberculosis, and comes to the following conclusions: (1) The present method of administration of Friedmann's remedy is free from danger; (2) in some forms of surgical tuberculosis it appears to have a favourable effect—in pulmonary tuberculosis it is very difficult to estimate its action owing to the capricious nature of the disease; (3) no decision is at present possible as regards its prophylactic value in children; (4) the present method of administration is probably not an ideal one—it is dangerous to dispense with other methods of treatment, especially the rest cure, and to depend upon Friedmann's remedy only; (5) the remedy has not fulfilled the great expectations entertained by Friedmann's admirers; (6) the way in which the remedy is advertised is reprehensible; (7) the clinician must say the last word as to its value.

481 The Tuberculosis Mortality in Vienna before and after the War.

PELLER (*Wien. Klin. Woch.*, October 7th, 1920) states that a comparison of the years 1919 and 1913 and 1914 shows an increase in the general mortality, and still more so in the tuberculosis mortality in Vienna, and that the mortality among women has become higher than that among men. Before the war the mortality was decidedly higher in every women. In 1919, on the other number of districts the mortality from tuberculosis among men was lower than that among women, in other districts the mortality among men was only slightly higher than that among women, and in only three districts was it considerably higher among men. The districts which were characterized by a considerable increase in mortality from tuberculosis were those which before the war were inhabited by a well-to-do population or by the middle classes. The poorer districts, though showing a larger number of cases than before the war, did not have such a large relative increase, possibly owing to the fact that during the war a large proportion of those affected in the poorer districts succumbed to the disease. The female population showed at all ages, with few exceptions, an increase in the deaths from tuberculosis from year to year. The amount of increase differed at various ages, being least between 20 and 40 and most marked between

15 and 20 and over 50. The increase in the tuberculosis mortality among the male population was smaller, with the exception of the age period 15-20. The highest mortality in men over 50 was reached in 1917.

482. Curability of Tuberculous Meningitis.

HARBITZ (*Amer. Journ. of Med. Sciences*, February, 1921) considers that tuberculous meningitis and tuberculosis of the central nervous system may be capable of cure, though it may be doubtful whether there was in any of the cases that recover inflammation at the base of the brain with partly gelatinous, partly purulent, exudate about the blood vessels and nerves. Observations go to show that tuberculous meningitis may heal, however, even in cases with rather extensive lesions with exudate and tubercle formation. Such curable form occurs in persons who have suffered from chronic and relatively benign forms of tuberculosis, though the most important factor is an increased resistance on the part of the body, with some relation to age. Sixty per cent. of cases occur in the first two years of life and are always fatal, cases of recovery being in older children and in adults. While epidemic meningitis generally becomes chronic with internal hydrocephalus, etc., tuberculous meningitis may heal without any serious defects even after extensive lesions.

483. Neo-salvarsan in Putrid Bronchitis.

SCHROEDER (*Acta Medica Scandinavica*, January 14th, 1921) records cases of putrid bronchitis in which the intravenous injection of neo-salvarsan in increasing doses (15, 30, 45 cg. at seven to ten day intervals) led to marked improvement, with a fall of temperature and diminution of expectoration. In one of his cases the disease had lasted five months; the temperature was high, and the sputum measured about 200 c.cm. In the course of twenty-three days the temperature fell to normal under this treatment, and the sputum dwindled to three lumps a day, losing its putrid character at the same time. HANSEN (*Ibid.*) endorses the treatment of putrid bronchitis by salvarsan, regarding it as a definite advance in the treatment of this condition, and he refers to three cases in support of his views. HOLMGREN and HOLST (*Ibid.*) both express doubts as to the value of this treatment, although Holst has seen some temporary improvement follow. SCHNELL (*Ibid.*), on the other hand, is a hearty advocate of this treatment, and he mentions the case of a patient with gangrene of the lung, following pneumonia. The temperature was high and the abundant expectoration putrid. Many different methods of treatment were tried without effect, but after three injections of neo-salvarsan the temperature fell rapidly, the smell and the quantity of the expectoration diminished, and the patient recovered.

484. Diabetes and Trauma.

DIEZ (*Il Policlinico*, Sez. Prat., March 28th, 1921) has collected the following statistics showing the frequency of trauma preceding diabetes: In 20 out of 225 cases (Griesinger); in 2 per cent. out of 4,068 cases (Frerichs); in 1.4 per cent. out of 938 cases (Seeger); in 5 per cent. out of 116 cases (Ebstein); in 1 per cent. out of 800 cases (Senator); in 5.6 per cent. out of 669 cases (Kütz-Rumpf). According to Lépine trauma is a cause of diabetes in 5 per cent. of all cases, but not an exclusive cause, as in many cases there is an hereditary predisposition. Cantani found a history of trauma in 10 per cent. out of 1,004 cases of diabetes, but, as Ferrarini observes, cases were included in which diabetes had occurred fifty years after the trauma. According to Brouardel and Richardière, traumatic diabetes is commoner in men than in women, while Lépine considers that children are most likely to be affected. Diez, however, thinks that these statistics have only a relative value, because the observers had not made an exhaustive inquiry into the etiology. While all writers admit the existence of a traumatic transitory glycosuria, some, like Jaccoud, deny the existence of a true traumatic diabetes, and consider that trauma only rouses pre-existing diabetes into activity. Others believe in the possibility of the development of traumatic diabetes when an hereditary or acquired predisposition is present. The opinion generally held is that of Richardière and Sicard, who maintain that the action of trauma is merely to awaken dormant disease. The region affected by the trauma is important. In 33 cases Brouardel found cranial trauma in 17, spinal trauma in 5, and traumata of other parts of the body in 11. The importance of cranial trauma is generally admitted. It is always severe, sometimes accompanied by fracture, in most cases with concussion. In some cases, however, no appreciable damage to the nervous system has been detected. Spinal trauma may be of various kinds, such as a fall on the neck, back, or lumbar region, or contusions in various parts of

the vertebral column. Sometimes there is a fracture and dislocation, while in other cases there is no surgical lesion, and only spinal concussion is responsible. According to Brouardel and Richardière, peripheral trauma of any degree is sufficient to cause traumatic diabetes, and it is not necessary that the part injured should correspond to a region in which the nerve centres are situated. Traumatic diabetes often appears early, sometimes within three days or a week of the injury, but there may be an incubation period of several weeks or as much as sixteen months. It is generally agreed that if diabetes occurs two years after an injury it has no relation to the trauma. The onset may be acute and the subsequent course rapid or slow, or it may be insidious and progressive from the first. The symptoms are the same as those of spontaneous diabetes.

SURGERY.

485. Renal Tuberculosis.

CASPARI (*Journ. d'Urol.*, Nos. 5-6, Tom. x) records 16 cases, 11 of which occurred in women and 5 in men. The patients' ages ranged from 18 to 57, the average age being 35. Anatomical examination showed that surgical tuberculosis of the kidney usually starts in the medulla, the pyramids being the favourite site; in only 2 cases was a cortical origin probable. In 8 cases the size of the kidney was not affected, in 5 it was enlarged, and in 2 it was unusually small, possibly congenitally so. In renal tuberculosis symptoms of cystitis predominate, consisting of frequent micturition, pain, pyuria, and haematuria. The renal symptoms are inconstant and less pronounced, and consist of pain in the back and in the right or left hypochondrium, sometimes radiating into the abdomen or the corresponding lower limb. The general condition is usually markedly affected, most of the patients showing loss of flesh, and some being subject to febrile attacks. On palpation the affected kidney is sometimes found to be large and tender and even movable, but often it is not detected by palpation, in spite of deep pressure. In exceptional cases the ureter is found as a round, hard, and exquisitely tender cord on abdominal palpation. The urine is turbid, purulent, and constantly acid. Caspari found tubercle bacilli in the urine in 12 out of his 16 cases. The other methods of detecting renal tuberculosis are cystoscopy and catheterization of the ureters. Cystoscopy shows that the lesions are most pronounced on the half of the bladder corresponding to the affected kidney, especially in the neighbourhood of the ureteral orifice. Catheterization of the ureters gives valuable information as to the condition of the ureter on the affected side. In most cases it shows strictures at the lower part of the duct which, in most cases, are impassable. These cicatricial lesions are almost pathognomonic of tuberculosis. Ureteral catheterization also enables a separation of the urine from the two kidneys to be made for naked eye, microscopical, bacteriological, and chemical examination. The urea and chlorides are deficient in the urine from the affected kidney. Treatment consists in nephrectomy as soon as the diagnosis is made, provided the kidney on the opposite side is healthy or at least functionally competent. The possibility of there being only a single kidney must not be forgotten.

486. Hydatid Thrill.

It is very generally held that a peculiar and characteristic thrill is pathognomonic of hydatid cysts. The cause of this thrill has very reasonably been attributed to the presence of hydatid vesicles in the fluid contents of the cyst. A similar thrill has, however, been felt in cysts containing nothing but fluid—as in some hydatids, ovarian, and broad ligament cysts, even in ascites. BÉRARD and DUNET (*Journ. d'Urol.*, January 1st, 1921) report a case of hydronephrosis of the right kidney which was mistaken for a hydatid cyst of the right lobe of the liver because of the characteristic "hydatid thrill" which they elicited from it. At operation the diagnosis was corrected, and nephrectomy performed. The case has a further interest, for two years previously the patient appears to have ruptured this hydronephrosis intra-abdominally by violent muscular effort—a most rare occurrence. The tear healed spontaneously. Bérard and Dunet refer to other French workers who have discussed the genesis of "hydatid thrill." They agree with Millan and Davaine, who believe that a thrill is likely to arise when fluid of a density corresponding to that of water is enclosed under high tension in a thin-walled cyst. The thrill is therefore not pathognomonic of hydatid cysts, though these most commonly fulfil the conditions necessary for thrill production.

487. **Hernia of Linea Alba.**

VILLARD (*Lyon Chir.*, November-December, 1920) discusses the pathogenesis and pathological anatomy of hernia of the linea alba. He states that these herniae are herniae of the round ligament of the liver. It is this which explains the paradoxical intensity of the disorders engendered by a lesion which appears trivial. The dyspepsia, the pain and its wide radiation are due to traction on the anterior hepatic ligament, which when herniated behaves like a pathological adhesion. Villard points out (as has Moschowitz) that a peritoneal sac is often lacking in the hernia, and when present is an accessory after and not before the fact. Until it was recognized that hernia of the linea alba was essentially a hernia of the fat walled in between the two layers of the falciform ligament it was difficult to understand why operation should bring such striking relief. When one realizes that resection of the herniated fat has released the tension on this ligament and the liver the good results of operation are better understood. Villard thinks that these herniae are always congenital, and are supra-umbilical because of the later closure of the upper mid-abdomen.

488. **Stoffel's Operation for Spastic Paralysis.**

GILL (*Journ. of Orthopaed. Surg.*, February, 1921), from an experience of 32 cases, believes the Stoffel neurectomy to be the best single operation in cases of spastic paralysis, because it is applicable to a great number of cases with uniformly good results, is not severe, and is not followed by any ill effects. Operations on the popliteal nerve were uniformly successful in relieving the contracture of the tendo Achillis, thereby enabling the patient to stand and walk with the foot firmly on the floor, thus greatly improving the gait. Operations on the obturator nerve corrected the adductor spasticity, and those on the sciatic nerve relieved the hamstring contracture. Median nerve operations lessened the spasticity or corrected the deformity of the hand in varying degrees, the results being more uncertain than those obtained in the lower extremity. When possible, a preliminary course of treatment should be undertaken prior to operation with a view to improving function as far as possible, and to enable the surgeon to decide better what extent of operation is needed. Through a small incision the nerve is freed from surrounding tissue, and the various bundles are tested by an electrode before excision. In cases of spastic paralysis of the lower extremities in which the contractures disappear under an anaesthetic no after-fixation is necessary, but if forcible correction is required to reduce the contracture the limb should be fixed in an over-corrected position for two or three weeks. At the end of a week, as soon as the wounds have healed, gymnasium instruction in muscle training and walking is commenced, but care must be taken to avoid over-fatigue, and active movements must not be overdone.

489. **Fractures of the Lower End of the Radius.**

HITZROT and MURRAY (*Amer. Journ. of Surg.*, February, 1921) investigated the factors that influence prognosis in fractures at the lower end of the radius. These are found to be the character and location of the line of fracture, the degree and variety of displacement, the degree and time of reduction, the after-treatment, and the age and temperament of the patient. Those cases which presented the greatest amount of disturbance in the radio-ulnar joint were found to show some deformity even when slight; and disability, most marked in supination and pronation, was a common result, especially in elderly persons. Such fractures may be separated into different groups according to the line of fracture as determined by x ray, and the earlier and more complete the reductions for similar types the better will be the cosmetic and functional results. Age has a definite effect on prognosis, similar bone injuries producing more disability over 50.

490. **Ulcer of the Cornea.**

TUTTLE (*New York Med. Journ.*, February 19th, 1921) discusses the treatment of ulcer of the cornea occurring in children and young adults, and in adults over 40 years of age. The phlyctenular variety is the one most commonly seen in children and young adults, largely as a local expression of a systemic disturbance—for example, a weak and scrofulous constitution, following the exanthematous diseases, or in tuberculosis or hereditary syphilis. Treatment consists generally in removal of the cause, and locally a saturated solution of boric acid as a cleansing wash followed by one drop of a 25 per cent. solution of argyrol instilled into the eye every three or four hours. Finely powdered calomel dusted on to the ulcers once a day hastens healing, and a compound yellow oxide and

adrenaline ointment is useful. Suitable glasses should be provided. Over 40 years of age the ulcers are usually of the serpinous or creeping variety, accompanied by an iritis, and rapidly extending. Prognosis is good if seen early. Foreign bodies, or cilia rubbing the globe, should be removed, and the conjunctiva flushed with a 1 in 5,000 bichloride solution. Under cocaine every part of the ulcer should be touched with the electro-cautery until all necrotic and infected tissue is destroyed, and the eye again flushed with the bichloride solution, a 1 per cent. yellow oxide and atropine ointment placed inside the lids, and the eye bandaged. The patient should be kept in bed and not allowed to remove the dressing himself, daily cleansing with boric acid solution being carried out. All abrasions of the cornea are serious, and require prompt and thorough treatment by the electro-cautery.

OBSTETRICS AND GYNAECOLOGY.

491. **Labour Obstructed by Fixation of Retroverted Uterus.**

POTOCKI (*La Gynéc.*, October, 1920) relates the case of a primipara, aged 38, in whom at the onset of labour at term the foetal head was found at the right side of the fundus uteri; the left half of the uterus was less perfectly developed than the right. An effort to perform external version having failed, hydrostatic dilatation by a bag was attempted, but with little success; it was possible, however, to bring down a leg. Next day, the child being dead and the uterus in a state of contracture, abdominal hysterectomy was performed; the fundus and posterior surface of the uterus were found to be adherent to the iliac and pelvic colon. Reviewing the treatment, Potocki points out that by a Caesarean operation performed on the first day of labour it would have been possible to secure a living child, and that as it was (the child being dead) the freeing of the uterus at operation would have been considerably simplified by previous removal of the limb which had been pulled down.

492. **Spontaneous Haematomata of the Abdominal Wall.**

BAUERISEN (*Zentralbl. f. Gynäk.*, March 12th, 1921) summarizes from the literature cases of spontaneous haematoma of the abdominal wall occurring in connexion with pregnancy and the puerperium. Such haematomata may be unilateral or bilateral and are generally unaccompanied by pyrexia; they are usually situated in the substance of the rectus abdominis muscle. They appear suddenly after a sharp muscular effort; their occurrence is usually to be correlated with the muscular hyperaemia and stretching which accompany pregnancy, but in a case recorded by Stoeckel the finding of petechiae suggested a purpuric etiology. The majority of cases have been treated by incision and evacuation of the clot, but Vogt's patient, in whom bilateral haematomata appeared in the lower end of the rectus muscle a few hours after labour, was found to present no abnormal signs, subjective or objective, at the end of four weeks' conservative treatment. The case of this condition recorded by Bauerisen is chiefly interesting with respect to etiology. At the date of appearance of the haematomata the patient was still suckling her youngest child (2 years old), but the genital organs appeared to be normal; at operation, performed within forty-eight hours, staphylococci were found in the exudate. Spontaneous haematomata of the abdominal wall may lead to considerable difficulty in diagnosis, and in some cases have been regarded, in the first instance, as pediculated ovarian cysts or as tumours of the colon.

493. **Subperitoneal Shortening of Round Ligaments.**

GRAD (*Amer. Journ. of Obstet. and Gyn.*, February, 1921) describes a new operation for retroverted uterus, in which he opens the broad ligaments and sutures the uterine end of the round ligaments to the internal abdominal rings. He often combines this operation with plication of the utero-sacral folds and a temporary suturing of the fundus to the anterior abdominal wall. He does not seem to agree with the accepted idea that very few uncomplicated retroversions give rise to symptoms.

494. **Fibroids Complicating Pregnancy.**

A DISCUSSION on the subject of fibroids complicating pregnancy took place at a meeting of the Obstetrical and Gynaecological Society of Nancy (*Rev. méd. de l'Est*, January, 1921), and among those taking part VAUTRIX came to the conclusion that in the early half of pregnancy it was only necessary to interfere when the growth caused com-

pression or caused incarceration of the uterus. In such a case he advised laparotomy and removal of the fibroid, if it were not too much imbedded in the wall of the uterus. In the presence of adhesions hysterectomy, disregarding the pregnancy, is the correct line of treatment. In the second half of pregnancy no operation should be done until term; then Caesarean section can be performed, followed by hysterectomy at once, or later. FRUHNSHOLZ quoted a number of successful cases, in some of which labour was not interfered with; in others the child had to be destroyed. VERMULIN noted that small fibromyomata sometimes caused delay in labour without any actual obstruction being present.

495. Carcinoma Vulvae.

FROM an analysis of forty-four cases of cancer of the vulva treated at the Kiel Frauenklinik, GIESECKE (*Zentralbl. f. Gynäk.*, March 12th, 1921) concludes that operative treatment gives better results than x-ray or radium therapy. Of the forty-four cases, twenty-five were older than 60, and eleven older than 70, while 18 per cent. were multiparous. The operative procedure recommended is excision of the vulva with bilateral extirpation of the lymphatic glands of the groin; recurrence of the disease occurred in four only of fifteen patients thus treated, as compared with five patients out of eight in whom hemi-amputation of the vulva, together with removal of glands on one or both sides, was performed. Lasting cure, as shown by five years' freedom from recurrence, was attained in 42 per cent. of operable cases; the primary mortality was 12 per cent. In two cases the pelvic glands were removed at laparotomy. Forty per cent. of the twenty-three cases in which the excised inguinal glands were examined microscopically showed evidence of carcinoma.

PATHOLOGY.

496. The Intradermo Reaction in the Diagnosis of Hydatid Disease.

SERRA (*Il Policlinico*, Sez. Chir., January 15th, 1921) states that Casoni's intradermo reaction for the diagnosis of hydatid disease consists in the injection into the dermis of 0.5 c.cm. of clear hydatid fluid obtained from an ox or sheep. In positive cases, within a few hours' time, there appear at the site of inoculation a more or less extensive erythema, pruritus, local rise of temperature, and oedematous infiltration. The reaction lasts some days, and even a week. A control test with injection of 0.5 c.cm. of normal saline solution is carried out on the opposite arm. Serra regards Casoni's reaction as a simple method within the reach of all. It is never positive in other diseases for which the echinococcus is not responsible, and it never gives rise to unpleasant results. The few cases in which the reaction is negative in spite of the presence of a hydatid are to be attributed either to conditions inherent in the cyst wall, such as calcification or abnormal thickening, or to previous suppuration of the cyst, which leads to the disappearance of the antigenic properties.

497. Relation between Haemoglobin and Number of Blood Cells.

GRAM (*C. R. Soc. Biologie*, January 22nd, 1921) gives a method for determining the corpuscular volume in blood and the relation between this volume and the haemoglobin and the number of cells. This is obtained by mixing 0.5 c.cm. of an isotonic 3 per cent. solution of sodium citrate with 4.5 c.cm. of venous blood and centrifuging the mixture in a graduated tube for ninety minutes at 3,000 revolutions a minute. The percentage volume is got by multiplying the amount of the precipitate by 100 and dividing by the quantity of blood in cubic centimetres. In normal men the percentage volume varies between 51 and 41, and in normal women between 45 and 36. The percentage volume of the corpuscles is directly proportional to the percentage of haemoglobin in normal cases, and in pathological cases approximately so. The examination of 611 cases of all kinds showed that 100 per cent. of haemoglobin (with 18.5 per cent. oxygen capacity) corresponds to a cell volume of 47.1 per cent. of the whole blood. A blood count of 5 million normal erythrocytes corresponds to a volume of 42-43 per cent. The "volumetric index" (the relation between the volume of corpuscles and their number) is given by the formula: percentage volume multiplied by 0.32 and divided by the number of corpuscles per cubic millimetre. The values of the volumetric index are closely related to those of the

colorimetric index. It is always to be borne in mind, as Gram points out, that the number of corpuscles corresponding to 100 per cent. of haemoglobin is not 5 millions, as is commonly supposed, but 5½ millions per cubic millimetre. Consequently the colorimetric index varies between 0.8 and 1, with an average of 0.9. Gram compared the volumetric and colorimetric indices in 550 cases which he divided into three categories: (1) 387 cases with a normal colorimetric index with an average of 0.9, in which the volumetric index was 1 on the average; (2) 36 cases with an average colorimetric index of 0.6, giving a volumetric index of 0.8; and (3) 127 cases with an increased colorimetric index averaging 1.45 in which the volumetric index was found to be 1.5. In the normal blood there is a difference of 0.1 between the two indices, which he attributes to the false data on which the haemoglobin index is usually calculated. The conclusion to be drawn is that the pathological differences of the haemoglobin index are essentially due to variations in the mean volume of the cells. In simple anaemias with low index the haemoglobin content per unit of volume of corpuscles is slightly below the normal; on the other hand, in cases of pernicious anaemia with high index the haemoglobin content is slightly above the normal.

498. The Etiological Significance of *B. proteus* vulgaris in Cholera Infantum.

PUPILLI (*Ann. d'Igiene*, December, 1920), as the result of his experiments, comes to the following conclusions: (1) Small laboratory animals, such as rabbits, guinea-pigs, and puppies, which have been given large or small doses of *B. proteus* cultures by the alimentary canal do not show symptoms resembling cholera infantum. The experiment was also negative when an attempt was made to favour the pathogenic action of the organism by causing an abnormal condition of the alimentary canal by alkaline substances or purgatives. (2) The death of small animals which had been made to ingest large doses of *B. proteus* cultures, accompanied by alkaline substances or purgatives, could be attributed to the toxic action of the organisms (endotoxins). Sucking rabbits showed less resistance to the action of *B. proteus*, and it was possible to kill them even with small doses of the culture given by mouth without first causing any artificial changes in the gastro-intestinal functions. These experiments show that *B. proteus*, though not constituting the etiological agent of cholera infantum, may have some importance in the pathogenesis of this disease when conditions are present to favour its development.

499. Jaundice following Injection of Salvarsan in Non-syphilitic Cases.

GOLAY (*Rev. méd. Suisse rom.*, November, 1920) records three cases of jaundice which developed from two to three months after injection of novarsenobenzol in non-syphilitic patients. The Wassermann reaction was negative in all, the diseases for which they were treated being lupus erythematosus, erythema multiforme, and soft chancre respectively. These cases prove that syphilis has nothing to do with the appearance of jaundice after the use of arsenical preparations. Golay does not think that the jaundice in these cases was a mere coincidence and was of the ordinary catarrhal variety, first, because he had not seen a single case of jaundice at the Geneva dermatological clinic which had not been preceded by injections of arsenical preparations, and secondly, because the jaundice in each case appeared about the same time after the injection. He therefore concludes that the jaundice was due to the salvarsan.

500. Auto-anaphylaxis in Paroxysmal Haemoglobinuria.

SCHIASSI (*Il Policlinico*, Sez. Med., Fasc. 9 and 10) records the case of a woman with a positive Wassermann reaction, who, during an attack of paroxysmal haemoglobinuria caused by a cold bath, showed a considerable diminution of the coagulability of the blood and a transient leucopenia of high degree, followed a few hours later by leucocytosis. In various incomplete attacks leucopenia was constant. By moderating the action of the cold, incomplete attacks—that is, attacks without haemoglobinuria—could be produced, the principal symptoms being diminution of the number of the leucocytes, nausea, and fever. It was impossible to reproduce two attacks in the course of the same day in spite of the constant presence of haemolysis and complement, because the first experiment which was followed by an attack caused a desensitization to the action of cold. Schiassi attributes the acute renal lesion in the attack followed by haemoglobinuria to occlusion of the renal tubules by granular detritus. Complete recovery took place under antisyphilitic treatment exclusively.

PIONEERS AND EMPIRE BUILDERS: No. 121
FOURTH PERIOD. circa 6000 to 2500 B.C.

TRADE
MARK

'TABLOID' BRAND

VICHY SALT

(EFFERVESCENT, ARTIFICIAL)

Reduced facsimile

Produces an effervescent aerated draught representing Vichy Water (Grande-Grille Spring) in all its essential constituents.

A very palatable preparation which appeals particularly to the patient.

May be prescribed whenever Vichy Water is indicated, and is ideal for use when increased consumption of water plays an important part in regulating health.

Portable tubes of 25 at 2/- per tube

TRADE
MARK

'TABLOID' BRAND

Carlsbad, Kissingen, and Vichy and Lithium Citrate Effervescent, Artificial Salts are also supplied at the same price, and Seltzer at 2/6 per tube.

RUDE NEOLITHIC FORMS AND DESIGNS IN WHICH ARE ALREADY RECOGNISABLE THE BEGINNINGS OF THE RELIGION OF THE GREEKS AND ROMANS.—The magico-religious beliefs and practices of Palaeolithic man—hunter and nomad as he was—seem, if we are right in judging from ethnographic analogies,

to have centred around his desire for success in the chase. His rites were the means by which he hoped to secure the animals upon which he was dependent for his daily food. Neolithic man, having made the stupendous discovery of the art of agriculture, evolved, as a consequence, a great new religious idea centring around the phenomenon of the earth's fertility. His rites should now aid him to procure a good harvest. Then for the first time the earth came to be looked upon as a mother, and it is supposed that in some way the idols and engraved designs reproduced on this page were meant for representations of the Earth-goddess. The results of archaeological exploration would seem to show that the Pioneers of these new ideas in religion were the dwellers in the Aegean area, whence the cult was transmitted west and north by way of Spain and the Atlantic.

CULTURE PHASE: NEOLITHIC

COPYRIGHT

ENO's Fruit Salt is a pleasant, effervescent, saline laxative, which bases its claim on its uniform standard of purity, on its agreeableness, and on its long record of popularity, due entirely to the experience of those who have taken it. Among those who have found it a helpful factor in maintaining a healthy activity of the digestive and metabolic functions are many doctors, both at home and abroad. ENO makes no claim to cure disease, but rather to assist in correcting some of the inevitable consequences of a civilised and artificial life to which man's physical structure has not yet become biologically adapted.

ENO's Fruit Salt is sold by chemists and stores throughout the world. A sample bottle will be sent free of charge to any medical man on application to J. C. ENO, Ltd., Blackfriars House, New Bridge Street, London, E.C.4. Only by trial and experiment can a just opinion of its quality be formed.

Remarks

ON

POSTERIOR RHIZOTOMY FOR THE
RELIEF OF PAIN.

BY

SIR WILLIAM THORBURN, K.B.E., C.B., C.M.G.,
CONSULTING SURGEON, MANCHESTER ROYAL INFIRMARY.

THE operation of posterior rhizotomy has been performed at intervals for the last thirty years; the first recorded case I have met with is one by Bennett,¹ in which some of the posterior lumbosacral roots were divided for sciatica, without much apparent benefit. Horsley,² Chipault,³ and others have recorded cases; while Abbé⁴ operated in two instances for intractable brachial neuralgia, excising the posterior roots and ganglia of the affected nerves, the result being that one case was somewhat improved and the other not benefited. The writer and others have also in the past deliberately divided the posterior roots of dorsal nerves in operating for tuberculosis and malignant disease of the vertebrae, with a view to the relief of pain caused by implication of such nerves as they pass through the intervertebral foramina. The earlier scattered cases have given somewhat doubtful results, but in some a persistent neuralgia has been completely cured by the operation.

The whole subject of rhizotomy came more prominently into notice with the publication of Foerster's work,⁵ and was brought before the profession in this country more especially by Hey Groves.⁶ In the *British Journal of Surgery* for October, 1914, are recorded a number of cases by various British surgeons, collected and analysed by Hey Groves, but since this date the war has largely diverted the current of surgical work, and in this country little more attention has been bestowed upon the operation.

Foerster adopted rhizotomy in connexion principally with three conditions—namely, the relief of spastic symptoms in the lower limb, especially those due to the cerebral hemiplegia of infants, the gastric crises of locomotor ataxia, and various types of pain. The present paper does not, however, propose to deal with the division of posterior nerve roots for the relief of spasm, as I have not adopted the operation for that purpose, and from the cases of others which I have observed I am not altogether satisfied as to its value, the difficulty of estimating which is largely increased by the fact that the operation has always been accompanied by careful nursing and instruction. We shall therefore for the present confine ourselves entirely to rhizotomy for gastric crises and for other painful conditions.

RHIZOTOMY FOR GASTRIC CRISES.

Gastric crises are conveniently divided by Foerster into two types:

1. The "Vagal," in which there is marked nausea, with but little pain or hyperaesthesia.

2. The "Sympathetic," in which pain and hyperaesthesia are common, but nausea is as a rule not very prominent. It is for the latter type of case that rhizotomy is principally recommended, and Foerster adopts bilateral resection of the dorsal roots from the fifth to the twelfth, with a view to cutting off entirely afferent impression within this area. He records 64 cases collected by himself, of which 6 died, 47 were cured or markedly improved, 9 underwent a certain amount of improvement, and 2 were unrelieved.⁷

In the *British Journal of Surgery* are reported 5 cases with no deaths, 2 failures, and 3 successes, but of the latter, 2 were too recent to allow of reliable inference. To these cases is added a sixth, in which death followed an operation for visceral crises in the bladder. Of the failures recorded in the *British Journal of Surgery*, one was a bilateral operation involving the sixth to the eleventh dorsal roots, and one, which involved only the eighth, ninth, and tenth on both sides, was probably too limited to give much hope of recovery. Of the successful cases, two were bilateral, involving the seventh to the tenth roots, and one case of my own, to which reference will be made immediately, was a unilateral division of the fourth to the eighth on the left side.⁸

⁸ In every case the numbers given are inclusive; thus fourth to eighth means fourth, fifth, sixth, seventh, and eighth.

Personally I have now performed this operation for gastric crises in three cases; and as two of these date back to the year 1914, they afford sufficient ground for judging of the permanency of the cure.

CASE I.

M., the patient already referred to as reported in the *British Journal of Surgery* for October, 1914, is now 51 years of age. He commenced to have gastric crises at the age of 34, the pain being limited to the left side and associated with copious vomiting. The attacks increased in frequency, and were eventually almost continuous, while the intensity of the pain required him to take large quantities of morphine. In March, 1914, the dorsal roots on the left side only were divided from the fourth to the eighth, both inclusive. Relief of pain was immediate, but three attacks occurred at considerable intervals during the first two years after the operation.

Since then there have been no further attacks, and up to the present time (February, 1921) the patient is entirely free from these. He naturally presents various symptoms of locomotor ataxia, but is quite able to go on with his business, and his general health is good. He presents loss of sensation to pin-prick from the level of the fourth to the eighth dorsal segments, and loss of sensation to cotton wool over a slightly wider area. There is no tenderness in the abdomen, even on very deep pressure. The sixth, seventh, and eighth motor roots have probably also been injured, as there is a little sinking in of the lower part of the chest on respiration, and possibly this may be due to degenerative changes in the anterior roots or cornua, as some paralysis was noticed at the time of operation and then passed away in a few days. There are no "trophic" changes of the skin.

CASE II.

B. was admitted to hospital for bilateral pain extending from about the level of the nipple to that of the umbilicus, more intense about the level of the eighth dorsal segment and relieved to some extent by pressure on the epigastrium. Attacks of pain were felt daily and were accompanied by profuse vomiting. I operated upon him in January, 1915, dividing the fifth, sixth, seventh, and eighth posterior dorsal roots, and thus perhaps not extending my section quite far enough down.

In January, 1921, this man was again examined. He presented anaesthesia to pin-prick from the fifth to the eighth dorsal segments on both sides, and to cotton wool over a rather more extensive area. There was no paralysis of any muscles and deep pressure was felt and roughly localized over the whole anaesthetic area; but there was no tenderness even on the deepest pressure over the subjacent viscera. The skin was normal. The patient states that attacks of pain recommenced about six weeks after the operation, and that they have continued ever since; but they now occur about once in six weeks, instead of daily as before the operation. His general condition as regards locomotor ataxia is bad, and he is much crippled by an arthropathy in the right hip, by difficulties of micturition, and by eye troubles, all associated with the primary disease. It is interesting to note that radiographic examination of the stomach showed on one occasion no abnormality, and on another some delay in emptying the viscera.

These two cases, then, present, after an interval of over six years, the one complete immunity and the other relatively great improvement as regards the crises, which alone the operation was designed to meet. The following is more recent, and does not yet offer materials for a judgement as to the end-result:

CASE III.

Mrs. W., aged 47, consulted me in October last, having suffered for twenty years from attacks of pain in the left side of the abdomen, with vomiting, and great exacerbation of these attacks during the last four years, so that latterly they had occurred every three or four days. She had had an operation performed on the gall bladder, but nothing pathological was there discovered. She presented typical symptoms of locomotor ataxia, which it is not necessary to detail. On November 8th, 1920, I exposed and resected the fourth to the eleventh dorsal roots on the left side only, producing the usual band of anaesthesia. The patient had two attacks of pain within the first week or two after the operation, but thereafter ceased to suffer from these for the six weeks during which she remained in hospital.

It will be noted that in these three cases Foerster's dictum as to the bilateral section of the fifth to the twelfth has not been followed, as I was doubtful whether so extensive an operation was essential. In the cases in which pain was limited to the left side the operation was unilateral only; in Case I, which was completely cured, it involved the fourth to the eighth thoracic roots; in Case II, which is so far relieved, the fourth to the eleventh roots were cut. In the partially relieved Case III the operation was bilateral, and concerned only the fifth to the eighth roots.

Apart from the main issue in the above cases, attention may be called to two points, namely, the completeness and permanence of anaesthesia, and the total absence of any

indication the affected parts; in both of which conforms to the results produced by dividing the sensory root of the Gasserian ganglion.

RHIZOTOMY FOR PAINFUL AFFECTIONS OF THE LIMBS.

A considerable number of cases of rhizotomy for pain in the limbs have also now been recorded. Foerster⁸ has collected 44, of which 6 died and 12 were cured, while 23 showed material improvement and 3 were untraced. In the British collection of cases already referred to there are 15 cases: In 1 the operation had to be abandoned, 1 died, and in 1 the result is unknown. Of the 12 which have been followed up, 8 were cured and 4 were failures. Several of the cured cases were examples of neuralgia of very limited type, in which only one root was divided, and more extensive painful affections were often apparently not relieved even by extensive operations. The great majority of the cases concerned the brachial plexus. The conditions for which the operation has been adopted are of the most varied nature. I have operated in two cases:

CASE IV.

A man had an injury to the right brachial plexus, followed by complete paralysis with anaesthesia and pain in the limb. The latter had, when he came under my observation in 1911, been amputated two or three inches below the shoulder-joint, naturally without giving relief. In March, 1911, I exposed the brachial plexus, finding a dense cicatrix, which extended completely up to the vertebral foramina. I excised the entire plexus, but without affording any relief to the pain.

In November, 1911, he was again admitted to my wards, and osteoplastic laminectomy was performed. The fifth, sixth and seventh arches were displaced. On opening the theca in the middle line, the dura mater was found to be closely adherent to the arachnoid on the right side, and had to be dissected away from the cicatrix thus produced. The roots of one only of the cervical nerves, apparently the sixth, were fairly well defined; but the remainder were contained in one cicatrix, which had to be dissected away from the spinal cord without differentiation between the anterior and posterior roots.

Recovery from the operation was uneventful, and the only marked change produced was paralysis of theilio spinal fibres, which had escaped or recovered from the original injury. Pain in the upper limb still continued, and two and a half years after the operation the patient wrote that although perfectly well and able to attend to his business, he did not think that he had obtained any material relief. It is clear that in this instance the roots of the plexus were avulsed from the spinal cord, and it is more than probable that changes had extended upwards in the central nervous system beyond the level of these roots.

CASE V.

J. received a bullet wound in the axilla in November, 1914, and in the early part of 1915 came under my care with extensive paralysis and anaesthesia of the left upper limb and severe causalgia. At that time I sutured the ulnar and inner head of the median nerve in the axilla without benefit.

He came under my care again in January, 1921; the muscles of the upper arm were in fairly good condition; he had slight power of flexion and extension of the wrist; all the intrinsic muscles of the hand were much wasted, the skin glossy, the nails long and curved, the wrist displaced to the radial side and the hand partially fixed in the position of pronation. There was continual pain in the palm, extending upwards in the front of the forearm for about one-third of the distance to the elbow joint—that is, roughly in the distribution of the median nerve; but, although pain appeared to be severe and operation was welcomed, it could no longer be described as typical causalgia. Atrophy and paralysis involved both ulnar and median nerves. No accurate determination of anaesthesia was possible, but there was patchy loss of sensation to both cotton-wool and pin-prick on both front and back of the useless hand; the limb was quite useless. The general health was a good deal undermined by pain and the use of drugs.

On February 3d, 1921, the fifth, sixth, and seventh cervical laminae were removed, and the sixth, seventh, and eighth cervical and first dorsal posterior roots were divided inside the theca, the ganglia not being excised. The fifth cervical root was not touched, as it was fairly remote from the affected area, and it was not thought advisable to run the risk of injuring motor fibres to the phrenic nerve. This man passed through one or two vicissitudes in connexion with an attack of influenza and sundry functional nervous phenomena, but by the end of

February declared himself free from pain, except for an occasional headache. Anaesthesia did not appear to be quite complete in any part of the limb, except the fingers, but the mental condition made accurate registration impossible. Light touches with cotton-wool were, however, generally not recognized in the area shaded in the diagram, but pin-prick was generally felt in the whole limb, except on the back of the fingers; deep pressure appeared to be recognizable everywhere.

These two cases are sufficiently indicative of the uncertainty of relieving severe neuralgia by posterior rhizotomy, and Case iv shows very clearly how some painful affections of the limbs may be associated with changes extending into the central nervous system. It is, however, remarkable that of the published records the greatest proportion of good results has been obtained in those cases in which, for a limited neuralgia, one root only has been resected.⁹ Beyond all question so limited a resection will not produce anaesthesia in the affected region, and the comparative success of the limited operation must be attributed to some other factor not yet fully explained. The existence of such other factor is also indicated by the success of my comparatively limited operations for gastric crises, and especially by that of Case i. It is also to be noted, both in the case of locomotor ataxia with gastric crises, and of long standing neuralgia in any region of the body, that the results of operation are

much confused by the highly neurotic condition of the patient. Many of these are accustomed to large doses of morphine, of alcohol, and of other drugs, and when in hospital they feel acutely the absence of such drugs. The case last mentioned showed various phenomena due to this cause. As a further illustration of the instability of the central nervous system in such patients, it is perhaps worthy of note that I have seen a case in which, after removal of the Gasserian ganglion, a typical hysterical anaesthesia involved the side of the body operated upon. A similar case has been recorded by Ormerod.¹⁰

In pleading for a more frequent use of rhizotomy, it appears to me important to point out that the dangers of the operation in practised hands are very much less than would appear from the published results. Thus, Foerster recorded 26 deaths out of 267 operations in which rhizotomy was performed for various reasons; and in the 53 cases collected from the *British Journal of Surgery* we find 6 deaths, the propor-

tion in each case being about 10 per cent. If, however, we investigate the figures of individual surgeons, who have presumably a larger experience in the operation, we find a very different result.

In Burghard's *Manual of Surgical Operations* (1909) I endeavoured to determine the mortality of laminectomy for all causes. An analysis of 50 of my own cases yielded a death rate of 6 per cent., several of which were early cases and were examples of injury or of tuberculous or malignant disease. I was then able to state that "exploratory operations and operations for tumours and allied conditions have been uniformly successful so far as life is concerned; and even in the earlier and more tentative operations for injury there is only one case in which death was probably hastened by operation." At that time I was not able to include any large number of operations for drainage, rhizotomy, or the removal of intrathecal tumours; but since then I have performed many such operations, and the only case of death has been that of an extensive sarcoma involving the cauda equina and conus medullaris, quite removable and associated with advanced secondary changes in the bladder and kidneys.

Kuttner has performed rhizotomy 32 times with 2 deaths, Eiselsberg 12 with no deaths, and Elberg 22 with no deaths. Adding my own to the above cases, we get 71 cases with only 2 fatal results; and every surgeon experienced in laminectomy will agree that the operation per se is not more fatal than that of laparotomy. Death is hardly to be contemplated as a result, except in cases where the original disease or the gravely deteriorated general health

CASE V.

introduces a special and serious factor. Even, therefore, if the results as regards cure of pain are still somewhat uncertain, and if we have more to learn as to the selection of cases and the scope of the operation, it is unquestionably well worth while to give these patients the considerable prospect of cure or relief offered by posterior rhizotomy.

SYMPTOMLESS HAEMATURIA:

A PLEA FOR EARLY INVESTIGATION.*

BY

JAMES B. MACALPINE, F.R.C.S.ENG.,

HONORARY SURGEON AND SURGEON IN CHARGE OF THE GENITO-URINARY DEPARTMENT, SALFORD ROYAL HOSPITAL.

I wish to direct your attention to the subject of symptomless haematuria, a condition of considerable importance, yet one which receives less attention than it merits; my main object in doing so is to impress on you the fact that such an occurrence is a matter of urgency until a full diagnosis has been made.

"Symptomless haematuria" is a term used to cover all cases in which haemorrhage occurs from the urinary tract unassociated with any other symptom or sign, such, for instance, as pain, urgent or frequent micturition, or a lump. The name is a bad one. In fact it is a misnomer, for haematuria itself, if evident to the naked eye, constitutes a symptom, and its occurrence can therefore never be symptomless. Perhaps it would be better if it were styled "unaccompanied haematuria."

Such unaccompanied bleeding is not at all uncommon, and may be the result of a very considerable number of pathological processes. Indeed there are very few of the many diseases of the urinary tract which do not sometimes give rise to haemorrhage, though with some of them bleeding is characteristic, whilst with others it is exceptional. If you will consider for a moment the vascularity of the organs concerned, it will not seem surprising that this is so. The kidney in particular is an organ of exceptional vascularity, and that portion of the bladder which is most susceptible to disease, namely the trigone, is also very rich in blood vessels.

Yet though so many lesions may be the cause of haematuria, in practice it will be found that unaccompanied bleeding is very suggestive of a urinary neoplasm. Indeed there is a well known dictum which states that "symptomless haematuria indicates a growth of the urinary tract." I quote this phrase to you with diffidence, realizing that medicine abounds with instances of similar dogmata, the majority of which are fertile sources of error and frequently denote a lack of scientific erudition. Yet it is with this probability in his mind that the surgeon will approach the investigation in any given case. That he will frequently find himself mistaken will be impressed on you if I refer to four cases of otherwise symptomless bleeding which have occurred in my own practice recently, and which on further investigation proved to be respectively:

1. A case of scurvy rickets.
2. A case of early renal tubercle.
3. One of that group of cases classified under the title of "essential renal haematuria."
4. Stone impacted in the pelvic outlet, in which, though the patient denied any history of pain, the parenchyma had been markedly encroached upon by back pressure.

Many other causes of symptomless haematuria might be recalled. Yet in a very large proportion of patients who pass blood in their urine without other symptoms, it will turn out that there is a neoplasm of the urinary tract. Walther, in a study of seventy-four cases of haematuria, both accompanied and unaccompanied by other symptoms,

demonstrated that over 50 per cent. were the result of urinary growths, and that of these 72 per cent. were malignant. If his article had only referred to cases of symptomless haematuria the percentage of growths would have been much higher.

Two matters require investigation in all cases:

1. The anatomical point from which the haemorrhage originates.
2. The nature of the pathological processes giving rise to it.

Now I submit that of these investigations the former is a matter of some urgency. The latter could be dealt with at more leisure, but you must know at the earliest possible moment whether the bleeding is from the upper or from the lower urinary tract, and in the first alternative from which side the haemorrhage is coming. This last is the important thing. A growth in the bladder may be seen when the haemorrhage has disappeared, but symptomless bleeding from the upper tract must be diagnosed during an attack, for then the bloody efflux from one ureteral orifice can be seen and the corresponding kidney, or ureter, held culpable. Remember that in all cases which are truly "symptomless" there is only one real guide, and that is the cystoscope. There is no pain; there is no lump. You may get some doubtful information from the presence of blood well mixed with the urine, which is generally held to come from the kidney; or from the presence of worm-like clots which have received their shape from the ureter; but these are unsafe guides, and even they will not tell you from which side the bleeding is coming.

If you wait till there are other symptoms to guide you, you will run the grave risk that the case will become inoperable, yet such procrastination happens with great frequency. Hinman, in an analysis of the published work of eight different surgeons, found that in 709 cases of renal growths haematuria was the onset symptom in 42 per cent., but that when the cases came to operation only 6.6 per cent. showed haematuria unaccompanied either by pain or tumour, and he justly remarks that this "indicates the lost opportunity in making an early diagnosis."

Any of the tumours of the urinary tract is capable of causing symptomless haematuria, and more commonly than not they express themselves in this manner. In order to keep my argument clear I will limit myself to two of the commonest tumours of the tract—namely, papilloma of the bladder and hypernephroma of the kidney. These happen also to be two varieties which very consistently give rise to symptomless bleeding; the former, according to Hurry Fenwick, showing this as its first symptom in 84 per cent. of cases, whilst Israel states that the latter expresses itself thus in 70 per cent.

There is considerable variation in the period of their life history at which they give rise to haemorrhage; in some cases we find that the first bleeding comes from a growth, papilloma or hypernephroma, which from its size must have been growing unsuspected for a long time. But in many cases it is quite early, when the growth is small. Such a haemorrhage coming from a small growth, whether of the bladder or kidney, may not be repeated before months, or occasionally even years, have elapsed, the growth in the meantime having become well-nigh untreatable. Surely this gives an uncanny importance to that single manifestation, and throws a grave responsibility on the medical practitioner to see that it is not allowed to subside without having been traced to its source. Generally the duration of that preliminary haemorrhage is not great—it is often only a few days or even hours. Denaciera states that in 146 cases of renal neoplasm only once did the primary haematuria last as long as fourteen days.

These two types of tumour each run a peculiar and almost invariable course, in that each in its earlier stage is non-malignant but in its later stage malignant. The papilloma in the early stage is single, has a long slender pedicle, and does not invade submucous planes. In the later stage it becomes multiple, sessile or sessile, shows the typical tendency of malignant neoplasms to invade and disseminate, and eventually destroys life by anaemia and cachexia. Singularly enough hypernephroma in its early stages is also a benign growth. It is encapsuled, and it grows very slowly. It may exist in this condition for many years—cases have been reported up to twenty years—behaving in exactly the same way as do parotid tumours.

* A portion of a lecture delivered at the Salford Royal Hospital to a post-graduate class (January, 1921).

Later it also takes on malignant changes, growing more rapidly, invading its capsule and the renal vein, and disseminating. It is remarkable that two growths in the same tract should share this somewhat rare characteristic, but it only makes the importance of an early diagnosis more self-evident, for in the early stage the treatment is that of a non-malignant neoplasm, is easy and satisfactory, and a complete cure can generally be achieved, whilst later the growth becomes malignant and the prognosis proportionately unfavourable.

Nature is, as it were, in each of these cases holding out to us in the early stages the option of successful treatment, if we are but wise enough and shrewd enough to avail ourselves of the opportunity, but she will just as certainly snatch away the proffered chance if we do not seize and secure it, and the indication which she gives us of this dangerous condition is the preliminary haemorrhage which is often so transitory.

To recapitulate, I have tried to show that haematuria is frequently the only symptom of a growth of the urinary tract; that following this expression of its presence it may retire into absolute quiescence for a long period, during which it is probably increasing in size and advancing towards malignancy; that when it reasserts itself, whether by a second haemorrhage, or by pain, or dysuria, or the presence of a lump, it may have passed beyond the operable stage, and that, if the growth should prove to be of the upper urinary tract, the only time at which a diagnosis of the anatomical site can be made is during the period of actual bleeding.

The moral is obvious, but I fear is often missed, and this I wish to impress on your minds. Haematuria is not a symptom to be treated *per se*. It is a red danger sign, urgently demanding an accurate diagnosis—first as regards its anatomical point of origin, and secondly as regards its pathological cause. It is an easy thing to put a patient suffering from acute abdominal pain to bed, and give a hypodermic injection of morphine. Such a course will be followed by relief of the pain; but the profession has long ago learnt the hazard of such a course so long as any doubt remains in regard to the diagnosis. Similarly, it is an easy matter to put a man suffering from haematuria to bed, apply cold, and administer certain reputed haemostatics. Such a course may be rewarded by a cessation of the haematuria, and the medical attendant will have the gratitude of his patient, but surely, on contemplation, must have the mortification of realizing that he has done him a great disservice. Much better had it even been if he had kept him in active life, and rather sought to perpetuate the haemorrhage than to allay it, till such time as a cystoscopic examination could be arranged, and the source of the haemorrhage accurately located. Once the haemorrhage is stopped the opportunity has passed, possibly for a long period, and unless some gross swelling of one kidney can be palpated, or the patient is persuaded to submit to a cystoscopy, which may reveal some causative bladder condition, the golden opportunity has gone by and may not recur till much valuable time has been lost.

Instances of such misguided treatment are unfortunately only too frequent in any urinary practice. I will cite a single case which I have seen comparatively recently. A man had had a short sharp haemorrhage from the bladder three years previously for which he had been treated by his medical attendant with cessation of the haemorrhage. From this point onwards there was no symptom at all till he began to suffer from discomfort in the bladder region and the sensation of incomplete emptying of the bladder even when he had just urinated. Cystoscopy revealed a growth of such large dimensions that examination was difficult owing to the instrument plunging amongst the fronds of a papilloma, which on account of its size had to be removed by suprapubic cystotomy, and when this was done there was revealed a pair of lesser "kiss-cancers" on the opposite bladder wall. If this patient had undergone cystoscopy three years previously his condition would probably have been treated rapidly and easily by diathermy, and the open operation would have been unnecessary.

As the growth gets older the attacks of haematuria tend to become more prolonged, severe, and frequent. On certain occasions I have had to undertake the examination of patients who have been under treatment for continuous haematuria for weeks, a few of these having become abso-

lutely blanched by loss of blood. In one instance a medical attendant informed me that he had attempted to knock off portions of growth by introducing a metal instrument and twisting it about in the bladder—a practice which is condoned in textbooks belonging to a past generation, but which obviously must be condemned in view of the possibility of ocular demonstration by modern methods.

These are the grosser errors, but I have nevertheless been much impressed with the late stage at which urinary growths reach the surgeon, and the consequent difficulty of obtaining good results in these cases. Indeed, if good results are to be obtained, the cases must come up at the first onset of symptoms.

That other urologists find the same trouble I am convinced. Braasch, in an analysis of a series of 83 cases of hypernephroma of the kidney, found that as an average haematuria had existed for more than a year in 77 per cent. before other symptoms precipitated treatment.

As a matter of fact the doctor is frequently not responsible for the delay, for patients often cannot be brought to realize the importance of the condition, so long as it is unaccompanied by pain or discomfort. I have on many occasions been astonished at the complacency with which patients, particularly amongst the uneducated classes, regard it, and have had on several occasions to use considerable pressure to persuade such to submit to a full examination of the urinary tract because they could not understand the importance of the condition. Bransford Lewis records the case of a man suffering from a hypernephroma of the kidney who carried about with him for six years a letter from his medical man to a consultant, in spite of the fact that blood was present in the urine all the time. Similar instances could be multiplied, though the duration in this case was extreme.

I have, however, laid emphasis on the responsibility of the medical attendant, because I consider the importance of an early cystoscopic examination has not been adequately brought home in the past. Had symptomless haematuria been as common as the acute appendix, it would have gone through the same phase that the acute abdomen experienced fifteen years ago, and would now be invariably submitted to immediate cystoscopy, just as the acute abdomen is invariably submitted to immediate laparotomy.

A SEROLOGICAL STUDY OF HAEMOLYTIC STREPTOCOCCI:

DIFFERENTIATION OF STREPTOCOCCUS PYOGENES FROM STREPTOCOCCUS SCARLATINAE.

BY

M. H. GORDON, C.M.G., C.B.E., M.D.,

BACTERIOLOGIST TO ST. BARTHOLOMEW'S HOSPITAL.

(From the Bacteriological Department, St. Bartholomew's Hospital.)

ALTHOUGH definite progress has been made within the last twenty years, knowledge concerning individual races included within the family of bacteria presenting the common morphology of Streptococcus is still at an early stage. It is now fifteen years since streptococci commonly met with in disease were investigated by Andrews and Horder with regard to their biochemical characters (Gordon), their haemolytic power (Schottmüller), and their pathogenicity for laboratory animals, and differentiated into three chief classes of *salivarius*, *faecalis* and *pyogenes*. This classification has stood, and to day the three groups of *salivarius* or *viridans*, *faecalis* or the enterococcus, and *pyogenes* or *haemolyticus* are widely recognized. As scarlet fever is a disease in which streptococci are constantly present, and have been suspected of primary etiological influence, a special study was made independently by Cumpston and myself of the biochemical characters of the streptococci present on the tonsil and fauces at the onset of scarlet fever. It was found that, as regards the characters in question, the particular streptococcus present there with the greatest constancy and in the greatest abundance could not be distinguished from specimens of *Streptococcus pyogenes* recovered from sources other than scarlatinal.

These past studies of streptococci, however, did not include a scrutiny of their serological characters. As recent investigations have shown in case of both the

pneumococcus and meningococcus that among cocci indistinguishable in biochemical or other respects a number of distinct and apparently fixed serological races or types exist which breed true. It was obviously desirable to investigate streptococci again from this point of view, and to attempt to define the degree of antigenic diversity obtaining amongst them. Accordingly, towards the end of 1919, a study of the serological characters of streptococci occurring in hospital cases was begun on behalf of the Medical Research Council. This survey is still in progress; while specimens of all classes of streptococcus have been included in the investigation, the hospital material examined hitherto has yielded so many more specimens of haemolytic streptococci than of the others that the observations with regard to this group are now sufficiently advanced to submit them to publication.

Preliminary Classification of the Streptococci.

Except in case of blood cultures which are made in broth in the ordinary way, the medium employed for primary isolation is blood agar prepared as follows:

Procedure.

An ordinary agar plate is poured and allowed to set, and then a melted slope of tryptic agar is mixed with a little blood from the finger and poured on the top of the agar. The thin surface layer of blood tryptic agar thus superimposed is ample for differentiating haemolytic colonies from others, and the medium is far more transparent, and the differences between colonies more evident than when blood is distributed throughout the medium. After a night's growth at 37° C. the sharply defined halo around colonies of haemolytic streptococci is readily seen on holding the inverted plate against a white background. Colonies of pneumococci at zone of haemolysis time, and both lytic streptococci colonies.

A single colony of the streptococcus is now carefully selected and subcultured on to a slope of tryptic agar the condensation fluid of which contains a drop of blood. In case of the haemolytic streptococci this condensation fluid shows well marked evidence of haemolysis next morning. Streptococci of the *salivarius* and *faecalis* groups as a rule fail to haemolyse the blood even after several days, but when *S. faecalis* is freshly isolated from the blood stream or from pus it not infrequently produces haemolysis; this coccus, however, is readily detected by the tests applied at the next stage.

The purity of the culture having been verified by microscopical inspection and ensured when possible by subculturing from a single colony on the tryptic agar slope, the next step is to test the ability of the streptococcus aerobically to ferment raffinose and mannite, and anaerobically to reduce the colour of neutral red broth. The raffinose and mannite are each in 1 per cent. solution, the solvent being ordinary meat broth with 1 per cent. of Witte peptone and 3 per cent. of salt; this broth is previously freed of its natural sugar content by cultivating *B. coli* in it, and litmus is added as indicator. In case of the neutral red, ordinary meat broth is used with addition of peptone and salt as before, and a suitable depth of colour is obtained by adding 2 c.cm. of a 1 per cent. solution of neutral red (Gruber) per litre. The reactions in these three media can be read off after forty-eight hours at 37° C. In case of some delicate examples of *salivarius* obtained by blood culture in malignant endocarditis, it may be necessary to add a drop of aseptic fluid to each tube in order to obtain growth. The reactions of the three chief classes of streptococcus in these tests is as follows:

Class.	Raffinose.	Mannite.	Neutral Red.
Progenes	—	?	—
Salivarius	+	—	+
Faecalis	—	+	+

While the vast majority of haemolytic streptococci fail to change mannite, a few do so. *S. salivarius* is uniformly negative in mannite, and *S. faecalis* as constantly positive in this test. Both *salivarius* and *faecalis* reduce neutral red under anaerobic conditions, but this test is not absolutely necessary; as its haemolytic power differentiates *pyogenes* from the other groups, and the two fermentation tests distinguish between *salivarius* and *faecalis*. It is important not to mistake the bleaching that *S. faecalis* usually produces in broth tinted with litmus for acid production; if the tubes are shaken and allowed to stand the colour returns, and the neutral tint of the raffinose is then seen to be the acidity of the mannite.

All the serological characters of the streptococcus are submitted to investigation. Owing to the tendency of suspensions of many of the commonest haemolytic streptococci to undergo spontaneous agglutination, the criterion of mere agglutination was abandoned at an early stage of the

inquiry, and recourse had to the absorption of agglutinin test, which has been found to be of no less value in defining the streptococcus group than it proved previously for a similar purpose in case of meningococci.

Procedure when Applying the Absorption of Agglutinin Test to Haemolytic Streptococci.

The method employed was similar to that used when investigating meningococci. So far little or no difficulty has been experienced in applying the absorption test to streptococci of the *salivarius* and *faecalis* groups. In case of the haemolytic streptococci, however, the difficulties at first were considerable and delayed progress for several months. Eventually these difficulties were surmounted, but in its application to the commonest strains of haemolytic streptococci the absorption test is still far from easy, and occasionally calls for considerable patience. For this reason the following details with regard to technique may be useful.

Preparation of Suspensions.—In order to obtain a dense suspension of the streptococcus, surface plates of tryptic agar enriched with aseptic fluid have been employed. After incubation for a night at 37° C., 2 to 3 c.cm. of distilled water is poured over each plate and the growth suspended therein. This suspension is examined microscopically, heated to 65° C. for one hour, and well shaken. One-tenth of a cubic centimetre of the suspension is then diluted and its density determined by a turbidity test similar to that employed when estimating the density of suspensions of meningococci. In the case of the majority of the haemolytic streptococci the sole use of this suspension was for saturation tests; the density required for this purpose being approximately 50,000 million particles per cubic centimetre. When working with the *salivarius* and *faecalis* groups far weaker suspensions than this suffice to remove the specific agglutinin from a serum. By adding the required amount of 85 per cent. saline the cocci used for saturation are suspended in 0.85 per cent. saline.

Selection of Type Strains.—The cocci used as index or type strains must satisfy two requirements: they must possess good agglutinogenic power, and they must make good suspensions, that is, suspensions of uniform turbidity that do not show macroscopically any auto agglutination in twenty hours at 55° C. While haemolytic streptococci vary in agglutinogenic power the selection of a good strain for this purpose is comparatively easy by experiment. The majority of strains of the commonest type of haemolytic streptococcus, however, exhibit a strong tendency to spontaneous agglutination, and for this reason are unsuitable for use as type strains. It was by good fortune that the earliest haemolytic streptococcus selected as a type strain was found to form excellent suspensions that were free from this tendency to auto agglutination. Later on, when another strain was substituted for it, the suspension was not satisfactory until the larger particles had been removed either by filtering the suspension through the thinnest filter paper, or by allowing it to stand in a cylindrical glass (a 100 c.cm. measure) for several hours so as to deposit these heavier particles. Having obtained a satisfactory type strain, it is advisable to make stock cultures of it at once, either on gelatine or egg medium, and to keep them at room temperature, so that should the strain after frequent subculture become supersensitive and take to agglutinating spontaneously, a fresh culture free from this fault can be obtained from the parent culture. This liability to auto agglutination is especially prominent in specimens of the commonest type of *S. pyogenes*. So far, it appears to be much less developed in examples of other types of haemolytic streptococci; and in case of streptococci of the *salivarius* and *faecalis* groups up to the present little or no difficulty has been met with from this cause.

Preparation of Agglutinating Serum.

Rabbits of from 1,000 to 2,000 grams were used, and the injections given intravenously at intervals of forty-eight hours, dosage being controlled by the animal's weight. The primary dose was 500 million of the killed suspension, and the final dose from 10,000 to 20,000 million. Haemolytic streptococci are weaker in agglutinogenic power to the rabbit than specimens of the *salivarius* and *faecalis* groups. In case of the former a titre of 1 in 400 is usually as much as can be obtained, though 1 in 800 is sometimes possible, especially with the rarer types, whereas in case of the non haemolytic streptococci serums with titres of 1 in 1,000 to 1 in 2,000 are easy to prepare.

Example of an Absorption Test.

The following are required: (1) A fresh suspension (50,000 million per c.cm.) in saline of each of the cocci to be tested and similar suspensions of the coccus homologous to the serum, and of a coccus of known heterologous type for use as controls.

(2) Sufficient of a dilution (one thirty-second of its full titre) of the type agglutinating serum to allow of 1 c.cm. for saturation with each of the cocci to be tested, and of 3 c.cm. in addition for the three controls—namely: (a) For dilution with saline only; (b) for saturation with the homologous coccus; and (c) for saturation with the heterologous coccus. (3) A centrifuge tube for each of the cocci to be tested and for the three controls. (4) A water bath at 37° C. for standing the centrifuge tubes in while saturation is in progress. (5) Racks of small tubes (3 in. by 2 in.) plugged with wool. (6) A 55° C. incubator.

Procedure.—One cubic centimetre of the diluted serum is placed in each centrifuge tube. One cubic centimetre of saline is added to the first, and a similar amount of each coccus suspension in turn to the rest. The centrifuge tubes are then shaken, placed in the 37° C. water bath and again shaken from time to time. After two hours at 37° C. the tubes are taken out and centrifuged till clear, after which the supernatant fluid of each is put up in four dilutions against an equal quantity ($\frac{1}{4}$ c.cm.) of a freshly made suspension (2,000 million per cubic centimetre) of the index coccus homologous to the serum. Two controls of this index suspension are also put up, one against saline, the other against normal serum diluted in the same way as the type serum. The racks are placed in the 55° C. incubator and the result read off next morning.

It is essential that the suspension of the index coccus should not be agglutinated in the controls of saline and of normal serum, and that the agglutinin should be removed by saturation with the homologous coccus, but unaffected by saturation with the coccus of known heterologous type. As a rule, cocci of the same type as the coccus homologous to the serum remove the agglutinin quite as completely as the homologous coccus. If there should be any doubt as to this absorption the test is repeated. The following is an example of the result of a saturation test carried out in this manner:

Type Serum and Coccus S.P.T.(1), Strain M.

No.		1:50	1:100	1:200	1:400
1	Normal serum	—	—	—	—
2	Type serum unsaturated ...	+	+	+	(+)
3	Type serum saturated with homologous coccus	—	—	—	—
4	Type serum saturated with heterologous coccus	+	+	+	+
5	Type serum saturated with Coccus A	+	+	+	+
6	Type serum saturated with Coccus B	—	—	—	—
7	Type serum saturated with Coccus C	(+)	—	—	—

+ = Well-marked agglutination.

As regards the controls, No. 1 proves that the index suspension is satisfactory since this has not agglutinated with normal serum; No. 2 shows that the agglutinin of the type serum is active; and No. 3 and No. 4 show that this agglutinin is absorbed by the homologous coccus, while it is unaffected by saturation with the heterologous coccus. Of the remaining three cocci, A fails to remove the agglutinin and is therefore of heterologous type, while both B and C have absorbed it, and therefore are homologues of the type coccus and agglutinin here employed. In the case of Coccus C, the saturation can if desired be repeated, since a trace of agglutinin still remains unabsorbed in the first dilution; but this is hardly necessary, since over three-quarters of type agglutinin has been absorbed; a degree of reduction that no coccus of heterologous type could effect.

Serological Types of Haemolytic Streptococci.

All the haemolytic streptococci submitted to serological investigation had been found to exhibit the cultural and biochemical characters of *S. pyogenes*. By the absorption of agglutinin test these streptococci have been resolved so far into three different types. In considering the frequency and distribution of these types it will be convenient to deal with the streptococci according to the sources from which they were isolated, and to take them in the following order:

1. Haemolytic streptococci from the tissues in ordinary hospital cases.
2. Those from cases of puerperal sepsis.
3. Those from the respiratory tract in various conditions.
4. Those from the tonsil at the onset of scarlet fever.

1. Haemolytic Streptococci from the Tissues of Ordinary Cases.

Either localized streptococcal infections or cases of streptococcal septicaemia or meningitis furnished all of

the 68 streptococci now under review. The actual sources and the number of specimens from each were as follows: Cellulitis 15, erysipelas 3, abscess 9, arthritis 5, meningitis 8, empyema 4, osteitis or osteomyelitis 3, otitis media 2, peritonitis 1, ophthalmitis 1, and impetigo 1. Streptococci were obtained by blood culture during life from one case of pyrexia of uncertain origin, from two cases of cellulitis, from a case of mastoiditis, and from one of pyelitis. Eleven streptococci were recovered *post mortem* from the heart's blood of the following cases: Trauma with septic wounds 2, septicaemia after hysterectomy for cancer 1, terminal septicaemia in pernicious anaemia 1, in secondary anaemia 1, in nephritis 2, in bronchopneumonia 2, in strangulated hernia 1, and in a case of gangrene of the leg.

No fewer than 66 of these 68 haemolytic streptococci were found to absorb the specific agglutinin prepared against one of them, and the group which they form was accordingly designated Type I. The two non-absorbing streptococci were injected into rabbits and agglutinin prepared against each, with the result that the cocci were found to represent two different types. The first of these streptococci, designated Type II, had been obtained in pure culture from the heart's blood of a rapidly fatal case of influenzal pneumonia. The last streptococcus, Type III, had been isolated from an ear discharge developed a few days before death by a girl of 9 in the last stages of rheumatic endocarditis, and was also recovered from the bronchial secretion after death.

2. Haemolytic Streptococci from Cases of Puerperal Sepsis.

Streptococci possessing the cultural and fermentative characters of *S. pyogenes* were isolated from ten cases of puerperal sepsis and examined. The actual sources from which they came were as follows: Cervical secretion 2, blood culture during life 5, blood culture after death 2, and one streptococcus came from the peritoneal pus in a case of abortion. On submitting them to the absorption of agglutinin test all of these ten streptococci proved to be specimens of Type I.

3. Haemolytic Streptococci from the Respiratory Tract.

Streptococci with the characters of *S. pyogenes* were isolated from the following materials: One specimen each from nasal secretion in chronic rhinitis and from laryngeal secretion in Ludwig's angina; two specimens from tuberculous sputum, and two more from the post-nasal secretion in chronic post-nasal catarrh. On submitting them to the absorption of agglutinin test all of these six streptococci proved to be examples of Type I.

Bronchial Secretion.—In order to determine the serological characters of haemolytic streptococci occurring in bronchial secretion this material was obtained *post mortem* at the bifurcation of the trachea and examined in 27 cases. No fewer than eighteen of these specimens of bronchial secretion failed to yield haemolytic streptococci. Although twenty of the cadavers showed pulmonary lesions, haemolytic streptococci were only isolated in nine instances. The positive cases were as follows:

(1) A girl of 9, with rheumatic "pancarditis" and terminal bronchopneumonia; (2) a man of 24 with acute pleurisy and myocarditis, fatal within forty-eight hours; (3) a child of 6 with bronchitis and empyema; (4) two men, one of 57 the other of 53, with septic pneumonia associated with breaking down of carcinoma in the lung; (5) a baby of 1 year and 3 months who had succumbed to acute bronchopneumonia—in this case the bronchial secretion showed chiefly *B. influenzae*, but a haemolytic streptococcus was associated with it, both in the bronchial secretion and in the heart's blood; (6) a man of 35 with tuberculous bronchopneumonia and meningitis; (7) a girl of 24 with morbus cordis and bronchopneumonia; (8) a man of 23 with bronchiectasis and amyloid disease of the kidneys, liver and spleen.

Out of the 9 haemolytic streptococci thus obtained from bronchial secretion no fewer than 8 were found by the absorption of agglutinin test to be examples of Type I. The single exception came from Case (1): It proved to be a specimen of Type III, and identical with a haemolytic streptococcus obtained from the ear discharge of this same patient a few days before death.

Tonsils.—The tonsil has been investigated for haemolytic streptococci by two different procedures—namely, either by direct examination of the freshly excised tonsil, or by swabs taken in the ordinary way. The opportunity of examining the freshly excised tonsils I owe to the

courtesy of Mr. T. H. Just, F.R.C.S., who removed them in course of his routine duties.

The tonsil was held in a piece of clean filter paper and its surface seared with a hot iron, the capsule slit open with a sterile knife, and three loopfuls of the contents distributed in 3 c.cm. of broth. A drop of this broth was then spread over the surface of a blood-tryptagar plate, and any haemolytic colonies isolated and examined. When dealing with swabs, the swab was stood in a tube containing 3 or 4 c.cm. of broth and well shaken; a drop of the broth was then carefully spread over a blood-tryptagar plate. The results were as follows:

Results.

Excised Tonsils.—Out of 24 tonsils removed from children for hypertrophy, and showing no definite naked-eye evidence of sepsis, 8 yielded a growth of haemolytic streptococci. Five of these streptococci proved to be specimens of Type I, one was a specimen of Type II, and two were specimens of Type III. Definitely septic (purulent) tonsils were examined after removal from two patients, the first of whom had developed rheumatic symptoms and endocarditis; in both cases the tonsils were heavily infected with a haemolytic streptococcus of Type I.

Swabs taken of the tonsil in four cases of acute tonsillitis yielded in three instances specimens of *S. haemolyticus* Type I, and in the fourth a haemolytic streptococcus apparently different from all the three defined types and not yet identified. A case of follicular tonsillitis and two cases of early measles accompanied by angina each gave a specimen of *S. haemolyticus* Type I. In three cases of diphtheria a haemolytic streptococcus accompanying the Klebs-Loeffler bacillus was a specimen of Type I. During an outbreak of infectious catarrhal sore throat in a school, six children in the acute stage and twelve convalescent children were swabbed by my colleague Dr. Richard Armstrong, and a special search made for haemolytic streptococci on blood-tryptagar plates. Only one case was positive, and the streptococcus there present proved to be a specimen of Type I.

Summary.—Out of a total of 21 haemolytic streptococci isolated from the tonsil and investigated 17 proved to be specimens of Type I, 1 of Type II, and 2 of Type III; one specimen could not be identified with any of these types. Including the haemolytic streptococci from all parts of the respiratory tract a total of 36 specimens have been investigated, of which 31 proved to be specimens of Type I, 1 of Type II, 3 of Type III, and one could not be identified.

The distribution of serological types among all the haemolytic streptococci examined up to this point is as follows:

Source.	Specimens.	Type I.	Type II.	Type III.
General	63	66	1	1
Puerperal sepsis ...	10	10	0	0
Respiratory tract ...	36	31	1	3
Total	114	107	2	4

The outstanding feature of these results is the pre-dominance of Type I, which undoubtedly represents the commonest form of *Streptococcus pyogenes*. It is of interest to recall that Hammetton examined six specimens of this streptococcus serologically and found them identical, and further, that in a recent monograph Douglas, Fleming, and Colebrook report a similar serological identity among twenty-four specimens of *S. pyogenes* isolated from war wounds. The last observers also found that the mannite-fermenting form of *S. pyogenes* is serologically identical with strains not fermenting mannite—a point which I can confirm, as 3 of my 107 specimens of Type I fermented mannite, while the remaining 104 failed to do so.

A further point calling for notice is that specimens of all the types of haemolytic streptococci were obtained from the respiratory tract. The two specimens of Type II came respectively from the heart's blood of a fatal case of influenzal pneumonia and from a hypertrophied tonsil. The four specimens of Type III came from three patients—two specimens from hypertrophied tonsils, the other two from the ear discharge and bronchial secretion respectively of a girl of 9 who succumbed to rheumatic carditis. It may be mentioned that among 125 haemolytic streptococci obtained chiefly from the respiratory tract during an outbreak of bronchopneumonia, Dochez, Avery, and Lancefield distinguished at least four different types by agglutination and by protection tests, and consider that further types exist in this locality.

4. Haemolytic Streptococci from the Fauces at the Onset of Scarlet Fever.

Having prepared the way by these control observations, I was now in a position to investigate the serological characters of haemolytic streptococci occurring in the tonsillar and faucial secretion at the onset of scarlet fever. From previous observations made on behalf of the Local Government Board it was known that at the earliest stage of scarlet fever a streptococcus indistinguishable from *S. pyogenes* in cultural and biochemical respects and virulent to the mouse occurs there with great constancy and abundance. It was of much interest, therefore, to see if this scarlatinal streptococcus is serologically identical with any of the defined types of haemolytic streptococci, and the present investigation appeared to be the more timely since observations recently published in America by Tunncliffe and Bliss had indicated that this scarlatinal streptococcus is serologically distinct from *S. pyogenes*.

For the present purpose it was indispensable to obtain material from cases of scarlet fever within the first week, and so typically clinically as to be beyond all doubt. Through the courtesy of Dr. Ford Caiger and the assistant medical officers of the South-Western Fever Hospital, I was provided with swabs from ten such early cases of scarlet fever. These swabs were treated in the same way as those described in the preceding section. Nine of them gave a profuse growth of colonies of haemolytic streptococci which in four cases far exceeded all other bacteria in abundance on the plates. From different parts of each positive plate two haemolytic colonies were subcultured and the cultural and biochemical characters of each streptococcus examined, with the result that all were found to be indistinguishable from *S. pyogenes* in these respects. Two of the streptococci that formed the best suspensions—each from a different case—were injected into rabbits and agglutinin prepared against each of them.

It was found that none of these 18 scarlatinal streptococci absorbed the agglutinin of either Type I or Type II *S. haemolyticus*.

On proceeding to carry out absorption tests with the agglutinin prepared against the two selected scarlatinal streptococci it was found that these two streptococci were identical, since each absorbed the agglutinin of the other equally as well as its own. Of the 18 scarlatinal streptococci 16 were found to absorb this agglutinin, and among these 16 was at least one streptococcus from each of the 9 positive cases. Specimens of each of the three defined types of haemolytic streptococci were now put up against the agglutinin of the scarlatinal streptococci, with the result that while Types I and II failed to remove it, Type III absorbed the agglutinin equally as well as the scarlatinal streptococci. It would appear, therefore, that the scarlatinal streptococci are identical with Type III.

Two of the haemolytic streptococci isolated from the scarlatinal throat failed to absorb the agglutinin from the serum prepared against the scarlatinal cocci, and also failed to absorb the agglutinin of the three types of *S. haemolyticus* previously defined. These two streptococci, therefore, are as yet unidentified.

SUMMARY.

1. By the absorption of agglutinin test haemolytic streptococci have been differentiated up to the present into three distinct groups or types.

2. Of these Type I is by far the largest. To this serological group belong the vast majority of specimens of haemolytic streptococci from localized or general streptococcal infections, from cases of puerperal sepsis, and from infections of the respiratory passages other than scarlet fever. Type I, in fact, represents *Streptococcus pyogenes*.

3. So far Type II is rare: only two specimens of it have been obtained.

4. Type III is chiefly to be found in the secretion on the tonsil and fauces in scarlet fever. Serologically this *Streptococcus scarlatinae* is quite distinct from *Streptococcus pyogenes*. The observations of Tunncliffe and Bliss to that effect are confirmed.

In view of this serological individuality of the haemolytic streptococcus present in the angina of scarlet fever it is clear that we must be prepared to revise our views on its significance in that disease. The opinion that this streptococcus represents merely a secondary infection in scarlet fever was based mainly on the view that it is

from specimens of *S. pyogenes* recovered than scarlatinal. This view is now untenable. The possibility, therefore, must be realized that the streptococcus in question may ultimately be established as the essential cause of scarlet fever. Its exact significance, and also its practical application as regards the diagnosis and specific treatment of scarlet fever have still to be decided. As the problem is one of considerable practical interest and importance, it is hoped that the present communication may be of use to others who may have the opportunity and inclination to investigate the matter.

In conclusion, I wish gratefully to acknowledge the help received from my colleagues at St. Bartholomew's and from Dr. Cniger in obtaining material for this investigation, and also to record the valuable assistance of Mr. J. Heagerty, my laboratory assistant, in applying the absorption test to the relatively large number of haemolytic streptococci that it has been necessary to examine.

Remarks

ON

POSTURAL OR SO-CALLED STATIC DEFORMITIES.

BY

A. S. BLUNDELL BANKART, M.Ch.CANTAB.,
F.R.C.S.ENG.,

ORTHOPAEDIC SURGEON, MIDDLESEX HOSPITAL; SURGEON, ROYAL NATIONAL ORTHOPAEDIC HOSPITAL AND HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

(Concluded from page 590.)

II.

In the first part of this paper¹ I gave a brief account of the physiology of posture, based on the work of Sherrington, who has shown that the upright attitude or posture of the body is maintained by continuous tonic reflex muscular activity. It was seen that this "postural activity" is of a special kind, quite different from the muscular contraction which gives rise to movement; that it is capable of being maintained for long periods without fatigue; and that it is controlled by a special nervous mechanism of its own. Attention was directed to the profound influence which the higher parts of the central nervous system exert upon postural activity, both in health and disease, and I endeavoured to show the practical bearing of these observations on the etiology and treatment of curvatures of the spine. Postural deformities are due to deficient postural activity, and the following pages deal with the application of this principle to flat-foot and other deformities hitherto described as "static."

FLAT-FOOT.

There are still some people who believe that the arch of the foot is supported by ligaments, and that the muscles merely serve to move the foot in obedience to the will. This view is utterly opposed to our conception of the function of ligaments and of the physiology of posture.

The natural form of the foot as a whole is determined by the shape of the individual bones, whose articular surfaces are adapted to one another in what may be called the neutral position of the foot.

The ligaments keep the several bones in normal apposition, resisting gross displacements, and helping to restore the bones to their normal resting positions after the slight displacements which continually occur during ordinary use of the foot. To this extent, and to this extent only, the form of the foot is maintained by ligaments.

It is not the function of ligaments to withstand continuous strain; this is a function of muscles. The correct attitude of the feet in standing is a part of the postural reflex which maintains the body as a whole in the upright position. The mechanical force of gravity in the upright position tends to abduct and evert the feet, and this actually happens in a child learning to walk before the postural reflex is established. The postural reflex, in so far as it concerns the feet, consists of adduction and inversion—which does not mean that the feet are visibly held in that position, but that the tendency to passive abduction and eversion by the body weight is continuously resisted. Incidentally, the inner border of the foot is drawn upwards to a greater or less extent, so as to form an arch, and the body weight is taken up by the postural muscles and distributed to the outer border of the foot, the heads of the metatarsal bones and the heel.

From this time onwards the normal attitude of the foot, including the arch, is maintained by continuous reflex muscular activity. This postural activity, as we have seen, is of a special kind, capable of being maintained continuously for long periods without fatigue, and controlled by a special nervous mechanism of its own.

Flat-foot is either caused by, or accompanied by, deficient postural activity. Some of the conditions which may modify or inhibit the postural reflex have been considered in connexion with scoliosis. Mental fatigue or inertia, temperament, occupation (apart from prolonged standing), anaemia, constipation, adenoids, etc., all have a place in the etiology of flat-foot as in that of scoliosis. The deficiency of postural activity may be manifested generally or locally. Some patients develop postural scoliosis or kyphosis, others postural flat-foot, while in many cases scoliosis and flat-foot are associated in the same individual as parts of a general loss of tone. Not infrequently there are accompanying vasomotor disturbances—for example, flushing, profuse sweating, susceptibility to chilblains, oedema, etc., significant of the functional (perhaps sympathetic) origin of the deformity.

But, although postural activity is capable of being maintained for a long time without fatigue, there is a limit to the amount of strain that even a postural muscle can stand, and under modern conditions of civilization the strain thrown on the feet is often far in excess of anything that Nature intended. The result is that in many cases simply by continuous standing the postural reflex is at last tired out, and the body weight, overcoming the resistance of the muscles, passively abducts and everts the feet. Prolonged standing is thus one of the commonest causes of flat-foot in adults. It is hardly necessary to point out that conditions which give rise to a primary deficiency of postural activity may be, and frequently are, combined with occupations which entail long hours of standing, so that both causes may operate together, and no sharp dividing line can be drawn between these two groups of cases.

There is a third class of case in which the postural reflex is inhibited by some local condition. Pain in the foot inhibits the local postural reflex. Flat-foot, therefore, commonly follows sprains, fractures, or other injuries of the foot (traumatic flat-foot) and painful inflammatory conditions, such as gout, rheumatism, gonorrhoea, etc. (inflammatory flat-foot). With regard to the last named affection, it may be said that reflex inhibition from pain has far more to do with the causation of gonorrhoeal flat-foot than has any inflammatory softening of the ligaments, as commonly described in the textbooks.

Cases of flat-foot, therefore, fall roughly into three groups:

1. Those in which the immediate cause is deficient postural activity;
2. Those which are due to continuous strain by which the postural reflex is exhausted; and
3. Those in which the local postural reflex is inhibited by some painful condition of the foot itself.

Pain in the foot not only inhibits the local postural reflex, but it frequently induces an abduction-eversion spasm, which is a fixation of the flexion reflex commonly evoked by painful stimulation of the foot. Spasm, therefore, is

usually present in cases of traumatic and inflammatory flat-foot, and it occurs also in a certain proportion of cases which are due to standing. It never occurs in the cases due to a primary postural deficiency.

It is common knowledge that a very considerable distortion of a joint may be brought about slowly and gradually in the course of time without provoking pain or spasm. But rapid distortion of a joint is painful, and quickly resisted by spasm of the muscles acting on the joint. Thus it happens that, when flat-foot develops slowly and gradually, as it usually does, it is unaccompanied by spasm, but when the deformity develops rapidly, it is likely to be accompanied by spasm. Spasmodic flat-foot is rapid and painful flat-foot. Spasm does not occur in the cases primarily due to deficient postural activity, because in them the deformity develops gradually, and is practically unresisted. It occurs in some of the cases which result from prolonged standing, because in them there is no primary loss of tone, the foot is in fact crushed down against resistance, so that the whole foot is strained, and the rapid distortion which results sets up a reflex protective spasm.

The arch of the foot is, perhaps, the least important thing about this badly named deformity. Some people have naturally high arches, and some have low ones. A very considerable amount of distortion and pain in the foot may occur before there is any apparent sinking of the arch, and some of the severest symptoms of flat-foot are met with in feet which are not flat. On the other hand, the arch may be low or even flat without any other symptom of flat-foot, and it does not follow that such a condition is pathological. Many barefooted savages have absolutely flat feet, yet they are perfectly normal. Their feet are strong and supple, they grip the ground as they walk, and they adapt themselves perfectly to every call that is made upon them.

The only thing that matters is whether the postural muscles take up the strain of the body weight, as they should, and distribute it to the best advantage to the natural points of support of the foot, or whether they are inefficient and allow the body weight to fall continuously unrelieved upon the joints and ligaments of the foot, so as to strain them and distort them and give rise to symptoms.

TREATMENT OF FLAT-FOOT.

The treatment of flat-foot is (1) to restore the natural form of the foot, if necessary; (2) to relieve the postural muscles from strain, or in other words, to keep the foot in the correct position during the period of recovery; and (3) to re-establish the postural reflex.

1.

If the foot is rigid or fixed by spasm, its natural form cannot be restored until it is made supple. Such feet, therefore, may require forcible correction and immobilization as a preliminary measure. I have, however, come to believe that spasmodic flat-feet can be made to yield to the corrective influence of a properly shaped boot, and I very rarely employ forcible correction and plaster now.

2.

Forcible abduction and eversion of the foot by the body weight throws a tremendous strain on the postural adductors, and these muscles cannot recover their function unless they are relieved from strain. It is necessary, therefore, before postural activity can be restored, to keep the foot constantly in a correct position, so that the muscles are relieved from strain. It is true that when the foot is supple this position can be voluntarily assumed. But voluntary muscular action is quite different from postural activity, and it cannot be sustained on account of fatigue. It is necessary, therefore, to employ some artificial means of securing the correct position during the period of recovery.

I have never been able to persuade myself that it is a rational or a scientific procedure to put a rigid support (foot-plate, arch support) under the arch of the foot. In the normal foot the inner border or arch is raised off the ground; there is an empty space beneath it, and obviously it was never meant to rest upon anything. It is also rather a tender part of the foot, and direct pressure upon it is not, as a rule, well borne. A rigid moulded arch support creates quite an artificial condition; it converts the elastic foot

into a rigid system, and I cannot but believe that it prevents that muscular re-education which is essential to true recovery.

Of course, if one starts from the point of view that flat-foot is incurable, it may seem rational to establish an artificial condition in which the arch is mechanically supported from below, as upon a crutch. But as a routine procedure, this seems to me to shirk the real treatment of flat-foot, just as the indiscriminate use of spinal supports in scoliosis is a confession of failure. Our experience is that comparatively few patients can tolerate rigid foot-plates, and that those who do can hardly ever dispense with them.

In the absence of normal muscular control the correct position of the foot is a question of balance rather than of support. The human foot has no true stability of its own. There is a mid position, on one side of which the body weight thrusts downwards and inwards, causing abduction and eversion of the foot, and on the other side of which the body weight flows downwards and outwards, the foot being adducted and inverted. There is no mean resting place, no point of stability in the mid-position. It follows, therefore, that the foot must be kept adducted and inverted to just beyond this mid-position in order that the postural muscles may be relieved from strain. This result can be obtained by giving the foot a tilt in the boot sufficient to throw the body weight definitely over to the outer side of the middle point. Nothing short of this degree of tilt will suffice; anything over it is enough.

To apply this principle in practice the foot must be held in a boot that fits well enough to make the foot follow its movements. It is then common practice to give the whole boot a tilt by raising its inner side. This is the principle of the so-called valgus wedge. A valgus wedge that is not sufficient is as useless as no wedge at all. One frequently sees boots with valgus wedges on patients who nevertheless crush down their arches, because the body weight still falls inwards. It is entirely irrational to prolong the heel in such a case, so as to support the waist of the boot from below. If the waist is crushed down the tilt is insufficient. If the tilt is sufficient the waist of the boot is not crushed down, and a prolonged heel is superfluous.

In my experience the simple valgus wedge commonly fails because the insole of the boot, although tilted, is still a plane surface. Upon an inclined plane surface the foot cannot find its natural points of support, but it slips bodily towards the lower or outer side, where it comes to rest against the "upper" of the boot. The natural points of support of the correctly placed foot are the heads of the metatarsal bones, especially the first, the outer border, and the heel. These parts of the insole must be depressed or "bedded," so that the foot may drop into them, and, if this is correctly done, the foot will adapt itself to the insole and assume its correct position. I have come to regard the moulded insole as the best of the artificial means of controlling the supple flat-foot, and I have found that at least some cases of rigid and spasmodic flat-foot will yield in time to this device.

3.

The only real cure of flat-foot is restoration of the local postural reflex. In cases of primary postural deficiency the treatment of the patient is of first importance. The general treatment of postural deficiency and of the conditions which give rise to it is indicated in postural flat-foot, just as in cases of postural scoliosis.

When the postural deficiency is local and merely incidental to the deformity, the treatment of the foot comes first. If the foot is supple, the patient can voluntarily invert it and stand on its outer border. This action is the same as that of the postural reflex, with this difference—that it is voluntary and phasic and therefore cannot be maintained, whereas the postural reflex is subconscious and tonic and capable of being continued for long periods without fatigue. The postural reflex can, however, be re-educated by voluntary action constantly repeated until it becomes habitual—or in other words, by exercises.

There is only one exercise which need be done for flat-foot, and that is the movement of inversion—getting on to the outer borders of the feet. The patient should be told, not to make a set "exercise" of it, but to do it always, everywhere, whenever he is standing about, to make a

fidget of it, until it becomes a habit and the attitude which it induces becomes habitual.

Set exercises t.d.s. do not make habits. A complicated series of exercises, if ordered, will be done only at certain fixed times, and the patient will not make of them a habit, as he will of a single simple movement which can be done at all times, anywhere, without preparation, and with hardly a thought. As a matter of fact, the majority of exercises are conceived with the totally erroneous idea of strengthening or developing certain muscles. Postural deformities are not due to weak muscles, but to deficient reflex activity. The object of exercises is to re-educate a reflex, and this is done by voluntary effort constantly repeated until the action becomes habitual or reflex.

There is only one person who can cure a flat-foot, and that is the person who has got it. The patient should be made to realize this, and his active co-operation should be secured. I have been accustomed to say that within limits the cure of flat-foot depends more on the patient's head—that is, his intelligence and co-operation—than on the state of his feet.

It is futile to order massage in an ordinary case of flat-foot or scoliosis. The patient who is having massage, and especially the patient who is paying for it, expects to be cured, and gets no further than that.

COXA VARA: GENU VALGUM.

There are certain other deformities which I cannot help thinking will eventually come to be included among postural deformities. They are particularly the coxa vara and the genu valgum of adolescents, hitherto described as constitutional, idiopathic, non-rachitic, non-traumatic—in other words, their pathology is unknown.

I quite agree that the more carefully one goes into the history of cases of coxa vara, the more often will one obtain a history of some preceding injury. But there still remains a group of cases in which injury can be definitely excluded, and I do not think that anyone claims a traumatic origin for adolescent genu valgum.

We have, then, a condition in which a bone or part of a bone which is normally subjected to great stress and strain from weight-bearing in the upright position, for some reason or other fails to resist that stress and strain, and becomes slowly deformed in consequence. All these cases show also flat-foot or other signs of deficient postural activity.

Now, every functional use of a tissue is in a sense an injury, or at least a stress and strain, to which the tissue reacts by calling to itself an increased blood supply. This is a local vascular reflex evoked through the sympathetic, and it is the normal mechanism whereby increased nutrition is secured to every functioning tissue, including bone. It is the explanation of the increased growth and development of a part which results from use, and conversely, the absence of this reflex is the explanation of the atrophy which results from disuse and still more so from paralysis. It may be taken as the physiological basis of Wolff's law, which briefly states that form and structure are determined by function. There is no evidence of the existence of any specific trophic nerves to the tissues of the body.

Now, if we rid ourselves of the idea of the older anatomists and pathologists that bone is a rigid unalterable structure, and if we regard bone as a living plastic material constantly undergoing changes of absorption, new formation and rearrangement, a structure which meets stresses and strains not by merely sitting under them, but by actively responding to them, calling to itself by reflex action increased nutrition, so that it may strengthen itself against them—in short, if we form a physiological and dynamic conception of bone rather than an anatomical and static one—we shall be able to view these deformities in a different light from that which has hitherto been usual.

We can picture to ourselves a bone suffering from the stress and strain of normal weight-bearing, and calling for that increased blood supply and nutrition which is so necessary but does not come, because for some reason or other the vascular reflex is in abeyance. In such circumstances, instead of strengthening itself to meet the stress and strain the bone simply becomes weaker, because function without physiological adjustment of blood supply, that is, nutrition, is pure destruction.

Thus we begin to see how a functional nervous condition might conceivably bring about such a surprising thing as actual structural alteration and deformity of a bone. For structure is the outcome of function; function is inseparable from nutrition; nutrition in functioning tissues is entirely a question of a co-ordinated blood supply, and the normal mechanism for co-ordinating the blood supply to any part is by means of reflex action through the sympathetic nervous system.

This activity of bone may indeed be described as postural. For, just as a postural muscle is called into activity by impulses arising within itself in response to the stimulus of gravity, so is the bone called into a state of physiological activity by impulses arising within it in response to the stimulus of weight-bearing.

A peculiar interest, therefore, attaches to the evidence which has been brought forward as to the sympathetic innervation of skeletal muscle, and to Sherrington's observation that the activity of the muscular walls of the blood vessels (which, of course, are supplied by the sympathetic) is also postural, that is, it exhibits the same features of plastic tonus—adaptability without change of tension, the lengthening and shortening reactions, etc.—as posturally acting skeletal muscle. These observations go to show that there is a close relation between postural activity of skeletal muscle and the weight-bearing capacity of bone, both being under control of the same nervous mechanism, and therefore liable to be affected by the same disturbances, whether functional or organic.

There is also an anatomical relationship between postural activity and weight-bearing. The internal structure of cancellous bone has been described as a "crystallization of lines of force"—that is, the lamellae are arranged in lines corresponding to the principal stresses and strains falling on the bone. In the trunk and lower extremities, at any rate, these lines are determined by the habitual positions of the bones in relation to the force of gravity in the upright position. These habitual positions are determined by postural activity, and any deficiency of the normal postural activity will therefore cause the lamellae of the bones concerned to come out of alignment with the force of gravity.

Anatomists describe certain mechanisms—for example, the Y-shaped ligament of Bigelow at the hip-joint and the locking mechanism of the knee-joint in full extension—whereby it is claimed that the upright position can be maintained without the necessity for continuous muscular action at these joints. But, as a matter of fact, the upright position is maintained by continuous muscular action, and these mechanisms do not come into action in the natural attitude of standing. It is true that when the muscles of the hip and knee are paralysed, stability may be secured by hyper-extending these joints until the checking action of the ligaments comes into action; but this is quite abnormal. In ordinary standing both the hip and knee are slightly flexed, and they can at any moment be extended or hyper-extended by an effort, but the attitude thus assumed is unnatural, irksome and fatiguing.

Deficiency of postural activity brings the lamellar structure of bone out of alignment with the force of gravity. The natural reaction of the bone is to bring about a re-arrangement of the lamellae in accordance with the altered direction of the stress and strain. But this is a slow process involving absorption and new formation of the lamellae, and meanwhile the bone is at a great disadvantage as regards its weight-bearing capacity.

I would put forward the view that lack of resistance, that is, inability to withstand the strain of weight-bearing, in parts of the bony skeleton may equally well be a result of deficient postural activity, as is the corresponding default of the postural skeletal muscles.

Thus, to deficient postural activity of central origin, as already described, we may assign some of the cases of coxa vara, genu valgum, and I may now add the osseous deformity of postural scoliosis, all coming on slowly at about the age of adolescence, and all associated with deficient postural activity of muscle.

CONCLUSIONS.

Postural deformities are due to default of the normal mechanism for maintaining the body in the upright attitude.

This mechanism is a nervous one, for it has been shown by Sherrington that the upright attitude or posture of the

body is maintained by tonic reflex muscular activity (postural activity).

Postural activity is of a special kind, capable of being maintained for long periods without fatigue, and controlled by a special nervous mechanism of its own. It is quite distinct from phasic or voluntary muscular contraction.

There is evidence that the sympathetic nervous system may be directly concerned with the postural activity of skeletal muscle.

The higher parts of the central nervous system—the labyrinth, the cerebellum and the cerebral cortex—have a profound influence on postural activity.

It is suggested that in many cases postural deformity originates as a functional nervous disorder, and that the cause is to be sought in the mental rather than the physical condition of the patient. Attention is drawn to the frequent association of postural deformity with neurasthenia and with a neuropathic family history.

There is a close relationship between the postural activity of skeletal muscle and the vascular reflexes which determine the blood supply, and therefore the nutrition of all functioning tissues, and it is suggested that herein may lie the explanation of the bony changes which occur in postural deformities.

Among postural deformities are included cases of scoliosis, kyphosis, flat-foot, coxa vara, genu valgum, and possibly others—all arising from the same common etiological factor: deficient postural activity in the upright position.

MEDICAL, SURGICAL, OBSTETRICAL.

DIFFERENTIAL STAINING OF CARCINOMATA.

Writing subject to correction, I have not hitherto noted any record of a histological staining method which enables one to pick out scattered carcinoma cells in sections illustrating very early secondary glandular invasion. It is obviously of first importance to be able to identify early carcinoma histologically, whether primary or secondary, and it is often extremely difficult to ascertain early glandular invasion where there are only discrete or scattered groups of two or three carcinoma cells in the section. The ordinary methods, such as haematoxylin and eosin, fail signally in such cases, the cancer cells being usually indistinguishable from the closely packed leucocytes in such sections. If, however, the section (not thicker than 0.03 mm.) is stained for ten minutes at 37° C. with Mayer's haemalum (British Drug Houses), washed in several changes of tap water and counterstained with Van Gieson's stain (Strangeways's formula) for fifteen seconds, and then dehydrated, cleared and mounted in balsam, it is quite easy to pick out the carcinoma cells individually or grouped in early glandular invasion, for they stain characteristically. The cytoplasm stains a dirty light brown colour and the nucleus a much lighter violet than that of the nuclei of the gland cells proper. The contour of the cell is typical and the eccentricity of the nucleus also aids one, but the point I wish to emphasize as so characteristic is the colour and prominence of the cytoplasm, especially with natural illumination.

If a gland with advanced invasion be cut it will be seen that the cells I have described partake of the same features as those of the growth masses. A little practice enables one to pick out carcinoma cells with ease and comfort. It is hardly necessary to add that the method is of as great or greater value in very early primary growths. I have found this method invaluable since I first used it, some two years ago, and I surmise that this record will be of interest to fellow workers.

AN OPERATION FOR RETROFLEXION OF THE UTERUS.

It seems to me that the varied operations on the round ligament which have for their object the cure of persistent retroflexion of the uterus are all open to question with regard to their efficiency. With this idea I have devised

the following method, which, so far as I am aware, has not been described before:

The abdomen is opened just above the pubes a little on either side of the mid-line. At a point on the external surface of the abdominal wall, about two inches from the edge of the wound and a little above the pubes, a ligature carrier of forceps pattern armed with stout silk is made to penetrate. When through the wall the blades are separated a little to widen slightly the aperture made; the carrier is then passed around the round ligament about an inch and a quarter from the uterus. Both ends of the silk are now grasped by the carrier and withdrawn through the aperture at which they entered, taking the silk, which being pulled upon brings out a loop of round ligament. This manoeuvre is repeated on the other side. The uterus will now be found to occupy the normal position. The next step is to dissect up a strip of the aponeurosis parallel with its fibres and at the edge of the aperture made; this strip should be about a quarter of an inch wide and of sufficient length to be passed easily under the loop of round ligament and stitched back in its bed with interrupted sutures. The round ligament is not stripped of its peritoneal covering, which will now line a new canal for the ligament to play in with the movements of the body. The abdomen is closed in the usual way.

With this method the entire length of the ligament is still of use if ever the uterus becomes pregnant. There is no chance of its giving way, and, owing to its proximity to the uterus, its support is permanently maintained. I visited to-day a multipara upon whom I performed this operation in the Gisborne Hospital six months ago, and without any prompting she said: "I have never been so well for years; I do not know myself; I am never irritable." Dr. Bowie, of this town, has since told me that he has performed this operation on four cases with complete success.

Gisborne, New Zealand. Consulting Surgeon, Gisborne Hospital.

DISLOCATION OF THE RADIUS FORWARDS AT THE INFERIOR RADIO-ULNAR JOINT.

ANTERIOR dislocation of the radius at this joint is perhaps of sufficiently rare occurrence to warrant description of a case, particularly as the lesion was produced as a result of a "back fire" when "cranking up" a car, and therefore constitutes one of the many so-called chauffeur's injuries.

The patient, aged 39, complained of pain in the right wrist from having previously received a blow from the starting handle of his car. When seen there was much swelling round the wrist-joint, tenderness on palpation, and pain on movement. In addition to some ligamentous tearing being present, a fractured carpal bone was suspected, and a skiagram was obtained which revealed a forward dislocation of the radius at its ulnar articulation. No evidence of any fracture in the carpus was apparent, and the wrist was carried forwards on the radius. The triangular fibro-cartilage had obviously been loosened and probably some of the lower fibres of the interosseous membrane were torn, in addition to the anterior and posterior inferior radio-ulnar ligaments. Reduction was not difficult, and full pronation was maintained with the wrist dorsiflexed.

It is now six weeks since the accident occurred, and there is full movement at the wrist-joint, with no undue laxity of the inferior radio-ulnar articulation.

I am indebted to Mr. John Murray for giving an opinion on this case.

LAMBERT ROGERS, M.R.C.S.,
House-Surgeon, Middlesex Hospital.

PREVENTION OF INTESTINAL OBSTRUCTION AFTER VENTROFIXATION.

MR. ALEXANDER DON, of Aberdeen, in his article on the prevention of intestinal obstruction after ventrofixation (April 16th, 1921, p. 563), recommends stitching the bladder and peritoneum above to the anterior surface of the uterus after reflexion of a corresponding peritoneal covering of the uterus, thus obliterating the space between uterus and bladder below the fixation stitches.

For years I have simply used a continuous suture to unite the two peritoneal surfaces, uterus and bladder, beginning at the reflexion between uterus and bladder and stitching up to the fixation stitches. The peritoneum is in this position fairly loose, and at the reflexion easily picked up by a pair of forceps. This completely obliterates the space. A number of pregnancies which have followed have been quite normal, as have also the labours, the last woman being delivered before either the nurse or the doctor arrived. There has never been any obstruction, to my knowledge, in any of the cases.

Reports of Societies.

TREATMENT OF LEPROSY AND TUBERCULOSIS WITH SODIUM GYNOCARDATE.

IN the Section of Tuberculosis and Pharmacology of the Royal Society of Medicine, on April 19th, Sir LEONARD ROGERS read a paper, detailing in large part experiences in India, on "The treatment of leprosy and tuberculosis with sodium gynocardate." This substance given subcutaneously, he said, had proved painful and slow in action, and therefore its injection intravenously had been tried, and the results were good. It was given in very slight doses (1/5 c.cm. of a 3 per cent. solution), and severe reactions customarily followed, after which the leprosy lesions tended to clear up. In one patient, an Indian of very high position, who had suffered from leprosy for twenty years, and had enormous thickening of parts of the face, the very minute dose given intravenously brought on a reaction which lasted for a month, and in the course of a year the whole of the thickened nodules disappeared, and altogether the patient showed the most remarkable improvement the speaker had ever witnessed in a case of such long duration. In another case an enormous lesion of the nose began to shrink after treatment and cleared up, a slight pitting only remaining. Attention was then turned to other substances, partly with a view to tackling the acid-fast bacillus of tuberculosis; in this condition, for fear of producing a generalized tuberculosis, he did not feel justified in using sodium gynocardate intravenously. The fatty acids of cod-liver oil were separated out and sodium morrhuate obtained, and experiments were also made with linseed oil (which yielded a product very irritating to the tissues), Japanese sardine oil (which was very toxic), and soya-bean oil (which gave rise to a product quite painless on injection and not toxic). Out of 51 leprosy cases treated with sodium gynocardate, one—the worst case he had ever seen—showed no improvement, 9 showed slight improvement, 20 very great improvement, and 21 complete disappearance of the lesions, with a bacteriologically negative result. With sodium morrhuate, out of 20 cases, 3 showed slight improvement, 12 very great improvement, and 5 the disappearance of the lesions. He made a later investigation, after the lapse of another year, on the earlier cases which had been treated with sodium gynocardate, and found that those traced had remained well or showed further improvement, save in 5 cases which had relapsed. In passing, he mentioned that he had worked out some figures which showed that leprosy had its beginning mainly in the first two decades of life; in 65 per cent. of the cases the original infection must have started before the age of 20. The same liability to infection in early life characterized tuberculosis.

The work on tuberculosis had not gone very far. He and five other medical men in India had tried sodium morrhuate in tuberculous lesions, and five of the six after a year got results showing definite improvement. One experienced civil surgeon had treated 18 cases of tuberculous glands of the neck, and in every case had brought about their disappearance, though in one case there was relapse. The speaker had treated one case of lupus with a new preparation—mercury morrhuate—rubbed in locally, and the case cleared up, and three similar cases by other observers were reported. The treatment promised better for chronic local tuberculosis than for pulmonary tuberculosis. Sodium gynocardate had been shown by some workers to have an action on acid-fast bacilli and sodium morrhuate to have no action, but even if sodium morrhuate had no action *in vitro*, undoubtedly in the human body it induced febrile reactions with breaking down of the bacillus. He thought that the success attending sodium morrhuate in lupus was hopeful, but he would not advise its use in pulmonary tuberculosis except by experts under carefully controlled conditions.

Dr. SHAW MACKENZIE suggested that lipoids would be of considerable use, and in tuberculosis preparations of the bacillus itself should yield fruitful results.

Sir LEONARD ROGERS replied that he had not used lipoids; he had all along preferred to use something foreign to the tissues—a substance not normally present in them—to one which could be isolated therefrom.

Kaolin in the Treatment of Cholera.

Dr. R. R. WALKER read a paper on "The action and uses of kaolin in the treatment of Asiatic cholera." He said that when hypertonic saline—as recommended by Sir Leonard Rogers—was used, the mortality was 22 per cent., and convalescents were discharged on the eighth day. With kaolin and hypertonic saline, the mortality was 29 per cent., and convalescents were discharged on the sixth day. In all the cases rectal lavage with kaolin solution was carried out. He found the combined treatment with kaolin and hypertonic saline was not as successful as that with kaolin alone. The latter brought about calm sleep, early cessation of the suppression of urine, and absence of relapses. He detailed the bacteriological and chemical researches he had undertaken, and demonstrated that the lethal alkaline fluid which resulted from the activity of the vibrio was rendered innocuous by mixture with kaolin. He expressed a wish that the substance should be tried in typhoid.

Sir LEONARD ROGERS pointed out that in order to get reliable statistics cases should be taken uniformly through a whole epidemic, as it was well known that towards the end of an outbreak the mortality was only half what it was at the beginning. With the hypertonic saline treatment he had had 20 cases without a death, but following such a series he might have one or two fatalities. He said it would be interesting to test the effect of injecting the toxic fluid and the kaolin together, for such a mixture would approximate to the conditions in the intestine when kaolin was injected. He agreed that the treatment now set out was worthy of further trial.

PLAGUE ON SHIPBOARD.

At the meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine held on April 10th, Dr. W. M. WILLOUGHBY, medical officer of the Port of London, read a paper on plague on shipboard. His chief point was to indicate the danger of the storeroom and its vicinity in relation to the origin and spread of plague from rat infection. He analysed the conditions obtaining in eight ships which, during the period 1917-20, came into the Port of London with cases of plague on board. In these eight ships, with a total complement of 1,715 persons, there were thirty-nine cases of plague. In five of the eight outbreaks the first person to be attacked was the storekeeper, and in three of these five the assistant storekeeper was also attacked. In other cases lascars, who were the first to be attacked, had been concerned with the issue of stores. Dr. Willoughby showed plans of the ships, indicating the position of the storeroom in relation to the berth of the men infected, and also the situation of the lavatory, which was an important consideration, because, if there was rat infection on board, the vicinity of the water supply was always a danger zone. Every hold of one of the ships contained rats which had died of plague, but the storeroom was the only focus of the human infection. It was possible for rat infection to exist for a long time without giving rise to human infection until some disturbance of the rat community took place. The first case of human plague occurred on one of the ships thirty-five days after leaving Bombay; this ship had called at Marseilles, where it was fumigated, and the human infection occurred subsequently. The rat infection had probably been simmering in the hold for weeks, but the fumigation, by interfering with the rats, precipitated the human infection. It was very important while fumigation of a ship was in progress that an effective rat hunt should be instituted on deck. By searching with canes in every possible recess he had caused to be captured nearly fifty rats on the deck of a ship after all the holds had been closed up. The disturbance of infected rats by cargo discharge was similarly dangerous, first to the ship's complement and then to the people at the port of discharge. In examining the history of any occurrence of plague on shipboard it was not sufficient to take into account the homeward voyage only, but the outward voyage should also be borne in mind, and perhaps even the previous voyage. The number of rats appeared to have no particular relation to the extent of the outbreak. The known rat history of one of the infected vessels only included 28 rats; in other cases, where the infection was no greater, the rats were numbered by the hundred.

In the course of a brief discussion, Dr. W. D. BETENSON, assistant medical officer of the Port of London, said that the cat history of one or two of the infected vessels was interesting. More than one of the animals—who were the pets of the storekeeper—had glandular swellings of the neck, but on the cats being killed, bacteriologists failed to find plague, although there were suspicious signs; it was a question whether cats, and also dogs, had not a certain degree of immunity which defeated the bacteriologist.

Dr. WILLOUGHBY, in replying on the discussion, gave some account of the steps taken in the Port of London to deal with suspected ships or ships from an infected port. Every parcel or box as it went over the side was watched, and if it was a well-packed bale or an unboxed box, which could contain no rat, it went on to its destination. But more difficult cargo, such as feathers, was put in a rat-proof storehouse for fourteen days. The passengers went ashore under a system of surveillance, whereby every name and address was taken and a notification sent to the medical officer of health for the district in which they intended to reside. In 85 per cent. of the cases the addresses so given were trustworthy. Answering another question, he said that in the tideway of the Thames, if a ship was four hundred yards out, a rat could have small chance of swimming ashore, but in slack water the case was different, and there a matter of another hundred yards might be important.

THE BLOOD GROUP IN MOTHER AND CHILD.

A MEETING of the Pathological Section of the Liverpool Medical Institution was held on April 14th, with the President, Dr. J. E. GEMMELL, in the chair, when Dr. FRANCIS B. CHAVASSE read a paper on "The blood group in infants and their mothers." He stated that a series of experiments upon this subject in the summer of 1919 showed that the blood group was determinable at birth by macroscopic test of the infant blood against stock serums. The incidence of the four blood groups in the newly born was identical with their incidence in adults. The rapid macroscopic test for the blood group yielded incidences of the various groups which were identical with the incidences obtained by more complicated methods; it might therefore be regarded as an accurate test (both for adults and infants). The blood group of the infant frequently differed from that of its mother, and twins might differ in this respect both from each other and from the mother. Where by reason of a difference in the blood group a condition which might be termed "maternal threat" to the child arose, the child's blood was invariably agglutinated by the serum of its own mother. But while the agglutinophilic receptors of the infant's corpuscles were thus invariably present at birth and enabled the blood group to be identified, the agglutinins themselves which were appropriate to the group thus identified were fully developed at birth in about 30 per cent. of cases, so that in cases of "foetal threat" to the mother the infant's serum agglutinated the blood of the mother (and of the other individuals of the mother's group) in 30 per cent. of such cases only. There was no obvious relationship between maternal threat and sterility or between foetal threat and eclampsia and the toxæmias of pregnancy. The fact, however, that agglutination *in vitro* was invariable in the former case and common in the latter showed that no immunity was acquired, the protective mechanism *in vivo* being referable therefore to the fact that dialysis of agglutinins via the placenta was not permitted by the intervening cells, at all events during life. The incidence of the blood group in lying-in women was identical with the normal adult incidence, nor was there any relation between the relative blood group of mother and child on the one hand and the sex of the child on the other. The transfusion of maternal blood into her infant as performed in cases of melaena neonatorum ought not to take place unless it had been previously demonstrated that both mother and child belonged to the same blood group. If they differed, as they did in one-third of all cases, another donor should be selected. The apparatus (made by Hawkesley) used in these experiments for performing the macroscopic test for the blood group was shown.

Professor E. E. GLYNN gave a demonstration of mechanical apparatus for use in the Wassermann reaction.

CAESAREAN SECTION.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow, on April 1st, Dr. JAMES H. MARTIN made a communication on a series of fifty consecutive Caesarean sections without fatality. Dr. Martin, in describing his technique at length, said it was a modification of that introduced by Professor Murdoch Cameron. His incisions were made about an inch and a half to the right of the middle line, two-thirds being above the level of the umbilicus. This utilization of the rectus and its sheath prevented subsequent hernia. There was the further advantage that as a rule this abdominal incision brought the operator right down on the middle line of the uterus. In making the uterine incision Dr. Martin always used a metal pessary, oval in shape and slightly concave, as suggested by Professor Cameron. In removing the placenta and membranes he turned the uterus inside out. Thus the uterine arteries were linked and the loss of blood was infinitesimal. The wall of the cavity of the uterus was now rubbed thoroughly with gauze, which might be termed a curettage. The difficulty in removing the membranes in the region of the os was lessened by sweeping the finger round beyond the internal os while the patient was being prepared for operation. In suturing the uterine wound the lowest suture was inserted and tied before the uterus was turned inside-in again, and this seemed to lessen the haemorrhage while the other sutures were being inserted and tied, particularly if the uterine arteries were not well compressed. The sutures were of silk, and interrupted. If the patient was not sterilized, mattress sutures of catgut were usually inserted along the uterine incision, the peritoneum and to some degree the superficial muscle being included in these mattress sutures. The peritoneum and posterior sheath of the rectus muscle were sutured together with a fine continuous catgut suture, and five or six silkworm gut sutures were inserted through the skin and the anterior sheath of the rectus, but not tied. The anterior sheath of the rectus muscle was now sutured with a continuous catgut suture, and the skin approximated by another similar suture. After cleansing the wound and the surrounding skin, a gauze pad was applied and anchored by tying the five or six silkworm gut sutures referred to above. Gavage tissue was applied and fixed with six-inch bandages. After the operation the patient was propped up in the sitting posture before being completely out of the anaesthetic. The advantage of this posture was that the lochia when shed flowed through the cervical canal into the vagina, and on to the pad, and was not retained in the uterus. Further, micturition and defaecation were not difficult in this position. With these modifications Dr. Martin had performed fifty consecutive Caesarean sections without fatality to mother or child.

At a meeting of the London Association of the Medical Women's Federation on April 12th, with Lady BARNETT in the chair, Dr. JANE WALKER read a paper on "Tuberculosis in children of school age." She said that great difference of opinion still prevailed as to when tuberculosis was acquired, but most people agreed that it was usually acquired in childhood, though its exact prevalence was still unknown, and percentages of incidence given by different competent authorities varied from 2 in 300 to 15 per cent. Her statistics showed that out of 800 children treated at the East Anglian Sanatorium, 1.5 per cent. gave a history of haemoptysis at the onset, and 20 per cent. a history of cough. A small number dated the onset from an attack of whooping-cough, and a still smaller number from measles. Usually the onset was insidious, with malaise or, more rarely, loss of flesh. The fact that a child came from a home where there was definite tuberculous disease apparently did not make its prospects any worse. Infection by contact appeared to be a far more important factor than infection due to hereditary predisposition. Where tubercle bacilli were present in the sputum the seriousness of the case was enormously increased in children, but the results of treatment in cases where tubercle bacilli did not occur in sputum were very good. Dr. Walker pointed out the importance of training the medical profession in the recognition of early signs of the disease, and suggested that a linking up of hospitals and tuberculosis dispensaries would be of much value to this end. A keen discussion followed.

the paper, in which Dr. R. Gordon, Dr. King, Mrs. Hogarth, Dr. Flora Sheppard, Dr. Mary Gordon, and Dr. Parsons took part.

A MEETING of the Manchester Medical Society was held in the Library of the Medical School on April 6th. The President, Dr. Goodfellow, was in the chair, and about sixty members were present. Dr. Goodfellow gave his presidential address, entitled, "Some aspects of preventive medicine." After giving a short historical account of the rise and present position of preventive medicine, he referred to the wide field still open for work in this direction and drew especial attention to the unsatisfactory position in this country of puerperal mortality, and to the need for increased knowledge in subjects such as infant welfare, health during the "pre-school" period, disorders of the heart, and tuberculosis. He emphasized the existing difficulties associated with the supply of pure milk and briefly discussed some methods of dealing therewith. After pointing out the essential factors in the organization of modern methods of preventive medicine, he urged the establishment of greater facilities for post-graduate study and for research work, emphasizing particularly the necessity for a large increase in resident institutional posts. With reference to administrative machinery Dr. Goodfellow put in a strong plea for the establishment of new local health authorities constituted *ad hoc*.

Reviews.

ORTHOPAEDIC SURGERY.

Surgeons generally, and orthopaedic surgeons in particular, will welcome the publication of *Orthopaedic Surgery of Injuries*,¹ edited by Sir Robert Jones. It seems a pity that this very important work could not have been published earlier, for the two volumes comprise a number of articles written by a variety of workers in the special surgical military hospitals, and embody the results of their experience during and since the war. Though injuries resulting from war wounds rather dominate the pages, the accidents common both to the soldier and the civilian are by no means neglected. The influence of the editor's teaching is evident in almost every page, but the writers of the various chapters have been given a free hand to express their personal views. Some overlapping must, we suppose, be inevitable in such a work, but the repetition of general considerations is rather apparent in the earlier chapters.

The first volume opens with an interesting article by Professor Keith on the principles and practice of H. O. Thomas, whose work is rightly considered to have had an immense influence on the later development of orthopaedic surgery. This is followed by a chapter on "Prevention of Deformity," which is sound enough on shock and sepsis as experienced among the recently wounded.

Lieut.-Colonel Joel E. Goldthwait, whose work is so well known in this country, contributes a chapter on the principles of orthopaedic surgery as they apply to the military need. In it he points out how much can be done to increase the number of efficient available for a fighting force by careful attention to posture and the care of the feet in the early stages of a recruit's training.

The bulk of the first volume is devoted to injuries of the bones and joints. Simple fractures are dealt with in an excellent article by Mr. W. H. Trethowan, which, however, would be much improved by illustrations, in which it is entirely lacking. The splinting of war fractures is dealt with by Captain H. G. Carlisle in an extremely well illustrated article. The choice of Mr. E. W. Hey Groves to write the chapter on ununited fractures is particularly happy; in it the causes of delayed union and non-union are fully discussed, as well as the principles involved in the operative treatment of fractures. It is of interest to note that light work is recommended early (five to six weeks) after bone graft operations, provided that the graft has been firmly fixed by splint pins or other metal fastening. Sir Robert Jones's chapter on malunion of the femur is, it need hardly be said, full of sound advice; while Mr. R. C. Elmslie on chronic osteomyelitis is equally sound. Mr.

Naughton Dunn and Mr. S. W. Daw write a thoroughly good chapter on disabilities of joints above the wrist. On the vexed question of the best position for ankylosis of the forearm there is some difference of opinion among the writers in this book. Dunn and Daw recommend the mid-position—that is, midway between full pronation and full supination, with a few degrees of pronation in a clerk's right forearm; later on Sir Robert Jones advises the mid-position, and Mr. W. I. Baldwin (Lieutenant-Colonel U.S.A.), in the next chapter, advises 35 degrees of pronation from the mid-position. The last position would certainly be considered too extreme by most surgeons, whatever their opinions as to the best position. It is apt to be forgotten that many, probably most, men, when seated at an ordinary table in a chair of moderate height, write with the forearm in a position of slight supination. The lower the chair the greater the supination. Moreover, by elevation of the elbow and internal rotation of the arm, lack of pronation can be compensated for, while no contortion can make up for lack of supination.

A carefully written article on the knee-joint is contributed by Mr. S. Alwyn Smith; in it internal derangement of the knee, including injuries of the crucial ligaments, are very fully discussed. Ankylosis and stiff joints generally are dealt with by the master himself, Sir Robert Jones. The chapter is full of useful tips and suggestions drawn from the writer's vast experience; though, as usual, he refers often and generously to the work of others. The same may be said of his chapter on flail joints. Mr. R. C. Elmslie contributes a relatively brief chapter on amputations and artificial limbs, and Sir J. Lynn-Thomas follows with a most interesting account of the centre for the limbless at Cardiff. Dr. F. C. Kidner, an American writer, deals with disturbances of the lumbar spine and pelvic girdle. In this excellent volume the hip is the only joint which does not perhaps receive all the attention it deserves.

The second volume is largely devoted to the injuries of the peripheral nerves. Every possible aspect of the problems involved is adequately dealt with in a series of excellent chapters. The illustrations in this volume are admirable. The anatomy is dealt with by the late Professor A. M. Paterson, diagnosis by Dr. T. Grainger Stewart and Dr. Rowley Bristow, and prognosis by Dr. E. Farquhar Buzzard; Sir Harold Stiles has written a chapter on the operative treatment, which is admirably clear and should be of the greatest service to the young surgeon. The illustrations of this chapter are partly coloured and are reproductions of drawings made during the course of actual operations. Mr. Rowley Bristow gives clear directions as to the post-operative treatment, and also, in a later chapter, details the requirements of an electrical department. The end-results of operations are dealt with by Captain C. Beresford Alexander, of Alder Hey, and Miss M. Forrester Brown, M.S., M.D., of Bangour Special Military Hospital.

The problems that arise when all hope of recovery of function after a nerve lesion has been abandoned are discussed by Mr. T. P. McMurray. Opinions differ widely as to the best muscles to select for tendon transplantation—in a case of musculo-spiral paralysis, for instance. It is, however, rather surprising to see that the radial flexor of the wrist, and not the ulnar flexor, is selected for attachment to the long extensor tendon of the thumb. His contention that the thumb and index finger work together and are therefore best moved by the same transplanted muscle, can, for the most part at any rate, be fulfilled by inserting the flexor carpi ulnaris into both—as well as into the tendons to the other fingers—the radial tendon being fixed to the two remaining tendons of the thumb; this plan seems to be preferable when considered with regard to the line of action of the transplanted tendon. He rightly insists on the importance of suturing a transplanted tendon with sufficient tension to avoid leaving any slack to be taken up by the muscle when it contracts, and advises "slight tension." Many surgeons would go further and advise "considerable tension." Most readers will wonder why the next two short chapters, admirable though they are, on injuries of the head and spine respectively, are inserted at all. Written by Dr. E. Farquhar Buzzard and Mr. Percy Sargent, they deal with the diagnosis and treatment rather than with any early or late results which might concern the orthopaedic surgeon.

¹*Orthopaedic Surgery of Injuries*. By Various Authors. Edited by Sir Robert Jones, K.B.E., CH., F.R.C.S. London: H. Frowde, and Hodder and Stoughton, 1921. In two volumes. (Roy. 8vo; vol. i, pp. 555, 206 figures; vol. ii, pp. 700, 268 figures. £4 4s. net two volumes.)

Functional and reflex disabilities, by Drs. Burrows and Morton, and trick movements by Professor F. Wood Jones, are the subjects of the next two articles; both are well illustrated. As many know, Professor Wood Jones, armed with his great knowledge of anatomy, has made a careful study of the muscles a patient may call into action in his efforts to imitate a movement that is normally produced by one or more of his paralysed muscles. He has collected a beautiful set of photographs.

The succeeding chapters deal with splints and plaster (Dr. D. McCrae Aitken), plain metal splints (Mr. R. Lane Joynst), massage (Dr. J. B. Mennell), the Ling system of exercises (Dr. G. Murray Levick), hydrotherapy (Dr. R. F. Fox), and x-ray work (Mr. C. Thurstan Holland). Finally, H.M. King Manuel, who gave so much of his time during the war to the organization and equipment of curative workshops, contributes an article on this subject, while the last chapter is written by Lieut.-Colonel Walter de M. Hill, on the organization and administration of a military orthopaedic hospital.

Some of the chapters in this volume are not, perhaps, quite up to the high standard of the rest, but the few faults to be found do not seriously detract from the excellence of the work as a whole. An enormous amount of useful information is contained in it, and every surgeon will undoubtedly turn to it for guidance in the classes of cases with which it deals. The illustrations on the whole are excellent. The editor and publishers are to be congratulated on the production of an epoch-making work.

THE INSTITUTES OF MEDICINE.

PROFESSOR J. J. R. MACLEOD and his collaborators in their admirable work on *Physiology and Biochemistry in Modern Medicine*² have achieved well-deserved success. It is a great tribute both to the authors and the medical profession that so large and expensive a book should have reached a third edition in the space of three years; it is a most cheering augury for the future.

Although all sections are not equally good and although no one would pretend to be in whole-hearted agreement with every line in the book, it gives a very fair and a very sane account of applied physiology and biochemistry, and it fills the place it was designed to take as "an advanced textbook in physiology for those about to enter upon their clinical instruction." It will be of even greater value as a reference book for those of more mature clinical experience who desire to understand the physiological facts underlying pathological conditions. After all, physiology and biochemistry are the basis of all true medical practice—of the interpretation of symptoms as well as the application of therapeutic agents. The study of the heart and the circulation and the factors which influence them is physiology pure and simple. In the laboratory the technique may be difficult and complicated, but the results obtained are more or less readily interpreted and, if necessary, new and drastic lines of experiment may be devised to elucidate the problem. At the bedside the methods available are strictly limited, the investigator is confined to one or two simple lines of experiment, and the interpretation is correspondingly more difficult. Careful and repeated observations on the patient based on sound physiology, such as is given in this book, will greatly help towards the solution of many of the outstanding problems. *Experientia docet*—provided we know what to look for. The modern clinician is, indeed, to be congratulated in having this work as his guide.

The changes made in the present edition are numerous, but they do not essentially alter the character of the book. The section on the nervous system has been recast and rewritten, and the chapters on respiration have been rearranged, the much discussed subject of anoxaemia being dealt with in some detail with special reference to its clinical aspects. Other sections of the book, such as those dealing with the endocrine organs, accessory food substances, ventilation, etc., contain much new matter.

The publishers are again to be congratulated on the get-up of the book.

² *Physiology and Biochemistry in Modern Medicine*. By J. J. R. Macleod, M.B., and others. Third edition. London: H. Kimpton, 1920. (Roy. 8vo, pp. 1074; 245 figures. 42s. net.)

DIATHERMY.

In *Diathermy, its Production and Uses in Medicine and Surgery*,³ Dr. CUMBERBATCH, the medical officer in charge of the Electrical Department of St. Bartholomew's Hospital, has produced a volume which traces the history of the subject from the time when the late Dr. Lewis Jones introduced the method into England in 1909. Nagelschmidt demonstrated its use on three surgical cases in St. Bartholomew's Hospital in October, 1910. One of these was a case of enlarged tonsils, in which diathermy was used to remove one and the guillotine the other; the contrast between a bloodless operation and the reverse was striking.

After an introduction and a historical note Dr. Cumberbatch deals, in the first place, with the principles on which high-frequency currents are produced; the next chapter is devoted to a description of various models of diathermy machines. Many diagrams illustrate this portion and make the letterpress clear to the reader. A short but practical note on the care of the apparatus follows. The physiological effects of diathermy are next discussed, with especial reference to arterial blood pressure, the pulse rate and the respiratory exchange. An interesting chapter is that describing some original experiments on the living subject in order to ascertain the effect of diathermy on temperature.

The main portion of the book consists of two parts, the first dealing with the medical, and the second with the surgical applications of diathermy; both are illustrated by photographs of cases before and after treatment, by diagrams of various kinds of electrodes, and by photographs of tissues which have been treated. The methods to be adopted in applying the current for medical purposes are accurately described; the electrodes, their application and situation, the regulation of the strength of the current, and the condenser couch all come under review. Sections follow dealing with the maladies for which this treatment is suitable, and indicating the methods to be used for each condition. Thus sciatica, neuritis, arterio-sclerosis, metatarsalgia, paralysis agitans, and so on, are all dealt with under separate headings. The chapter on the uses of diathermy in surgery commences with a description of the local effects produced by "diathermic coagulation," and a discussion of the actions of different methods of cauterization. The important point is that diathermy raises the temperature of a part till its coagulation occurs *in situ*; the blood and lymph are coagulated and the vessels sealed, whilst infective organisms are destroyed. The essential points of many cases of malignant disease are narrated, and the method employed, dangers to be avoided, and the results obtained, described; cases illustrating the complications which may occur are reported.

The author has produced a book which is a valuable addition to the literature of his subject. It has the advantage of being based almost entirely upon his own work and experience, and sets out very fully the scope of diathermy both in medicine and surgery. Its general construction, the meticulous care for detail, the easy style in which it is written, together with its comprehensive character, should ensure its success as a textbook. Those who practise this treatment should read it carefully, and keep it at hand for reference.

CLINICAL MICROBIOLOGY.

A NEW edition of BEZANÇON'S⁴ well-known work on clinical microbiology will be welcomed by those who desire to improve their bacteriological methods, and especially by those who look to France for guidance and help in such matters. The ingenuity and originality of the French is always refreshing, and those who desire a synopsis of recent developments will not be disappointed in the present book.

As a preface Bezançon reproduces an inaugural lecture given by him in Paris in March, 1919, wherein he outlines the progress of bacteriology during recent years, and traces the stages by which it has developed from the

³ *Diathermy, its Production and Uses in Medicine and Surgery*. By Elkin P. Cumberbatch, M.A., B.M., M.R.C.P. London: William Heinemann (Medical Books), Ltd. 1921. (Demy 8vo, pp. 205; 44 figures. 21s. net.)

⁴ *Précis de Microbiologie Clinique*. By F. Bezançon. Third edition. Paris: Masson et Cie. 1920. (Post 8vo, pp. 931; 7 plates, 200 figures. Limp covers, 30 fr. net; boards, 35 fr. net.)

simple examination of a film or culture, or an animal inoculation, until it has come to touch upon some of the most delicate problems in physiology. He ends by emphasizing the need of constant daily co-operation between physician and bacteriologist in order to interpret the phenomena observed by each.

The book is divided into five portions. Part I deals with the general characters of bacteria, and also includes a synopsis of current knowledge of immunity. Part II is devoted to technique, including the preparation of culture media, special culture methods, methods of isolating bacteria in pure culture, and methods of estimating the various antibodies. In Part III the pathogenic bacteria are described in turn. Part IV is devoted to a description of the bacteria of the normal human body; and Part V deals with the bacteriological analysis of blood, sputum, urine and pus, including the examination of water and air.

The scope of the book is wide, and it is not surprising that the author takes nearly 900 pages to cover the ground. It is practically impossible for one man to maintain a uniform standard of excellence in all the fields here attempted, and perhaps the chief merit of the present work is to be found in the account of particular infections such as sporotrichosis and spirochaetal jaundice, which are both dealt with in considerable detail and with much success. It is surprising to find no reference to the work of the Lister or the Rockefeller observers on the serological types of pneumococcus, to the work of Tulloch on the types of tetanus, or to the apparatus of McIntosh and Fildes for the culture of anaerobes. It would seem that there is considerable scope for someone who will undertake to evangelize the French with regard to British work! But if the present book ignores the contributions of British workers, these can be studied elsewhere. The chief merit of Bezançon's monograph lies in the fact that it is a compendium of current French methods and views on a subject of growing complexity and importance.

MANIC-DEPRESSIVE INSANITY.

THE volume entitled *Manic-Depressive Insanity and Paranoia*⁶ is a translation from the eighth German edition of Professor EMIL KRAEPELIN'S *Lehrbuch für Psychiatrie*. Miss MARY BARCLAY, who is responsible for rendering this book into English, has already translated *Dementia Praecox and Paraphrenia*, by the same author, so that the most important clinical publications of the celebrated German psychiatrist are now accessible to the English reader. The conception of manic-depressive insanity as a separate morbid entity has been evolved entirely upon a basis of symptoms and outcome, and Professor Kraepelin is unable to throw any light on the nature of the disease. In view of the great amount of research which has been devoted to this and other forms of mental disorder at the Munich clinic, it is somewhat disconcerting to read that we are still in a state of complete uncertainty as to the meaning and significance of the symptoms they exhibit. In respect to manic-depressive insanity the principal causal factor is to be found in a morbid predisposition, and an hereditary taint was demonstrated in about 80 per cent. of the Heidelberg series of cases.

The description of symptoms and the delineations of the various forms which this disorder assumes alone render this book worthy of the most careful study, but many psychiatrists will be inclined to doubt how far it is justifiable to regard this type of morbid reaction as a definite disease entity. There can be no disputing the fact that this conception is a most convenient clinical generalization in so far as it serves to bring a number of cases with certain symptoms in common under one heading. While, however, the recognition of these symptoms in a given case has undoubtedly a certain prognostic value, so many atypical cases are met with in actual practice that the diagnosis between dementia praecox, manic-depressive insanity and other forms of disorder is often a matter of extreme difficulty. It is almost true to say that if a case gets well we call it manic-depressive insanity, and if not, dementia praecox. Especially is this the case in the hallucinatory and mixed forms of manic-depressive insanity to which Professor Kraepelin devotes so much attention in his book. It

is probable that many who read the life-like descriptions of the four forms of disorder included in these two volumes will be inclined to feel that they shade so imperceptibly into one another that no definite boundary lines can be drawn between them. In the future we shall perhaps tend to take a much wider biological, dynamic view of the psychoses, and in this way obtain a much greater insight into and understanding of the significance and meaning of mental disorder. Professor George M. Robertson seems to imply some such view in his brief editorial preface to this volume. We agree with him also when he writes that the medical profession is under a debt of gratitude to Dr. Mary Barclay for her faithful rendering into English of these classical studies.

NOTES ON BOOKS.

WE had occasion not long ago to review the first edition of Dr. GUILLAUME'S work on the sympathetic nervous system.⁶ That a second edition has so soon been called for is sufficient testimony to its interest and value. Much new material has been embodied, particularly in the sections dealing with the morphology and physiology. Fresh chapters deal more completely with the clinical and pathological aspects as well as with diagnosis. A full and excellent bibliography is added. In its enlarged form this book should find a wide circle of readers, constituting as it does a comprehensive survey of a subject which is now attracting so much study and attention.

Under the title of *The Story of the Horton* (Co. of London) *War Hospital: Epsom*,⁷ Lieut.-Colonel J. R. LORD, C.B.E., M.B., has published an account of the history of the transformation of the civil institution now known as the Horton Mental Hospital into a very different form of activity, which is very interesting, and the immense amount of labour and the fertility of the schemes which it entailed reflect great credit on Dr. Lord and his colleagues. In addition to the general history of the hospital during the war there are chapters giving an account of the detailed work of the special sections of the hospital. In the section on the mental department of the hospital there are some interesting conclusions by Dr. Lord, who, although his time was fully taken up with administration duties as officer commanding, naturally had a considerable interest in war psychiatry. He considers that the war did not occasion any new form of mental disorder, and that in pre-cases of mental breakdown there was probably a predisposition not to all, but to one of the generally recognized forms of mental disease, excluding, of course, definite brain lesions. The form the individual is predisposed to is settled by constitution, conditions of early life—pre- and post-natal—adolescence, early sex and emotional experience, and education. The stress of war would appear to have been more potent in hurrying on mental symptoms, causing them to appear at an earlier stage in the development of the predisposition than ordinary civil causes of mental breakdown would have effected. Dr. Lord must be congratulated not only on the interesting volume which he has produced, but on the valuable work which, in face of many difficulties, he and his hospital achieved during the war.

Of the bound volumes of *Transactions* that have come to us recently for review one is published in this country and two in the United States. The forty-third volume of the *Transactions of the Medical Society of London*⁸ records the scientific proceedings of that Society during its 147th session. The longest contributions are the three Lettsomian Lectures by Dr. Herbert Spencer "On Tumours Complicating Pregnancy, Labour, and the Puerperium," which were printed a year ago in our own columns; the Annual Oration by Sir D'Arcy Power on "The Rev. John Ward and Medicine"; and the Presidential Address by Mr. V. Warren Low "On Surgery during the War."

The forty-fourth volume of *Transactions of the American Gynecological Society*⁹ is in large part devoted to a

⁶ *Le Sympathique et les Systèmes Associés*. By A. C. Guillaume. Preface by Professor Pierre Marie. Second edition. Paris: Masson et Cie. 1921. (Demy 8vo, pp. 419; 49 figures, 18 francs net.)

⁷ *The Story of the Horton (Co. of London) War Hospital*. By Lieut.-Colonel J. R. Lord, C.B.E., M.B. London: W. Heinemann (Medical Books), Ltd. 1920. (Demy 8vo, pp. 264; 7 plates, 1 p. illus., 12s. 6d. net.)

⁸ *Transactions of the Medical Society of London*. Forty-third volume. Edited by Donald Armour, C.M.G., F.R.C.S., and William Henry Wilcox, C.B., C.M.G., M.D., F.R.C.P. London: Printed for the Society by Harrison and Sons. 1922. (Demy 8vo, pp. 245, illustrated.)

⁹ *Transactions of the American Gynecological Society*. Volume 44 for the year 1919. Edited by George Gray Ward, Jan. M.D. Philadelphia: Wm. J. Dornan. 1919. (Demy 8vo, pp. 427; illustrated.)

⁶ *Manic-Depressive Insanity and Paranoia*. By Professor Emil Kraepelin, of Munich. Translated by R. Mary Barclay, M.A., M.B. Edited by George M. Robertson, M.D., F.R.C.P. Edin. Edinburgh: J. and S. Livingstone. 1921. (Demy 8vo, pp. xv+280; 49 figures, 21s. net.)

record of the proceedings of the annual meeting held in the summer of 1919 at Atlantic City, under the presidency of Dr. Franklin H. Martin of Chicago, whose introductory address on "Gynecology as a Specialty" forms the first item. The discussion on radium treatment of uterine cancer which took place in the previous year at Philadelphia, was resumed by Dr. Harold Bailey of New York, whose paper is freely illustrated. In his conclusions Dr. Bailey stated that "so great has been the palliation from the radium that it may be said that no uterine cancer case receives proper treatment without thorough radiation of the tissues of the pelvis."

The thirty-second volume of *Transactions of the American Pediatric Society*¹⁰ contains the papers read during the annual meeting at Highland Park, Illinois, last summer under the presidency of Dr. Thomas S. Southworth of New York, who in his opening address argued in favour of the segregation of cases of pneumonia. An interesting paper on the food requirements of children, estimated in calories, was contributed by Dr. L. Emmett Holt in conjunction with Miss Helen L. Fales. They maintain that the total daily calorie requirement of children of either sex during adolescence exceeds by nearly 1,000 calories the requirements of the adult man or woman of moderate activity.

Messrs. H. K. Lewis and Co., Ltd., have just published a Supplement (1918-20) to the Catalogue of their Medical and Scientific Library,¹¹ with a list of additions to March, 1921.

¹¹ *Supplement 1918-20 to the Catalogue of Lewis's Medical and Scientific Circulating Library* London. H. K. Lewis and Co., Ltd. 1921 (Demy 8vo, pp. 65, 1s net.)

APPLIANCES AND PREPARATIONS.

A Direct Record Scotometer.

MR. N. BISHOP HARMAN, F.R.C.S. (London), writes: In recent years much attention has been paid to the mapping out of the central fields of vision. The chief difficulties in this kind of perimetry have been due to the slowness of the means of taking the observations, so that the patient got tired, vitating the results, and, secondly, there was no satisfactory means of making a direct and permanent record of the observations. For the past two years I have been using an instrument which overcomes these difficulties. It consists of a rigid iron stand to which is fitted a frame carrying the screen against which the observations are to be made. The screen is of grey cloth, fixed into it in the central position is a small white metal stud; this is the fixation point. Behind the screen is a sheet of carbon and a paper chart ruled into the usual degree circles and radii. Red and blue tracing papers are also supplied, which enable three records to be taken, at intervals, on the same chart. The object is carried on a suitable object-holder and held in the surgeon's hand, which is obscured from the patient's view by a grey cloth bag glove. At the back of the frame knobs are fixed in the usual positions of the blind spots, so that the surgeon has a reliable guide from which to work. In taking observations the patient's face at the naso-buccal groove is pressed against the knob on the free upright of the stand. One eye is covered, the other looks at the fixation spot. The surgeon moves the object over those parts of the field he desires, and notes when the patient sees it and when he does not. The records of the observations are made by pressing the small style on the back of the object holder against the screen, when the impress is conveyed by the carbon sheet to the chart. The whole of the movements of the object over the screen may be traced in this fashion by a light continuous pressure, and salient points marked by deeper pressure. The method is so simple that the surgeon has no need to watch his own movements, so can concentrate his attention on his patient's face and secure that his fixation is constant. The real advantage of this recording instrument is the speed and accuracy with which observations may be made. The instrument has been made for me by Messrs. John Weiss and Son, Ltd., of 287, Oxford Street, London, W. 1.

A Urethral Drainage Bougie.

DR. HENRY DUTCH (London, W.) writes: The treatment of gonorrhoea, as practised by the Austrian medical officers at Colford Camp, was described in the *BRITISH MEDICAL JOURNAL* of March 1st, 1919, p. 245, by Major Foxart, M.C. Believing the method to be sound, but crude and painful in its application,

I have had made for me a drainage bougie of the following character. It is simply a tubular mesh of white silk closed at one end, through the centre of which runs a thin vegetable fibre. Its length is about 8 in.; the central core, being several inches longer and being flexible, allows easy insertion. The urethra having been cleared by urination, a sterilized urethroscope tube with a pilot is introduced. The pilot is then with-

drawn and the drainage bougie, saturated with any desired solution, such as permanganate of potash, protargol, acriflavine, is introduced. The urethroscope tube is now withdrawn, leaving the drain in situ. Finally, the central core is pulled out, leaving the drainage tube in the urethra. The drain gives no discomfort and is well tolerated. The advantage of this method is that all parts of the mucous lining come into contact with the antiseptic employed, and there is no risk, as in syringing, of driving the pus into the posterior urethra, which I believe is a common cause of cystitis, prostatitis, and orchitis. This method might also be employed for the drainage of small sinuses, fistulae, etc. The silk bougies, and a glass introducer, have been made for me by the Victoria Scape Company, Ltd., 1 Wood House, Fulwood Place, Holborn, W.C.1.

TUMOUR OF THE BLADDER AMONG WORKERS IN ANILINE FACTORIES.

AMONG the duties imposed on the International Labour Office, set up as part of the organization of the League of Nations, is the protection of the worker against sickness, disease and injury arising out of his employment. In order the better to carry out this duty, a special Industrial Hygiene Department has been formed and placed in the charge of Dr. Carozzi. It has recently produced a report in which a historical account is given of the observations by which a relation was established between the occurrence of tumour of the bladder and work in aniline factories, and the prophylactic precautions which have been taken, seemingly with success, are enumerated.

In 1895 Rehn published three cases of tumour of the bladder in workers in an aniline factory in Frankfurt-on-Maine, and since that time a number of similar cases have been reported. The first cases occurred among workers engaged in the preparation of fuchsine and aniline. Inquiries were carried out in a number of factories over a series of years, but no definite conclusions were reached. In 1912 Leuenberger published 18 cases observed among the workers at Basle handling aniline dyes, and a commission was then appointed. The total number of cases reported to it was 177; it is questionable whether some of the cases should have been included. The figures given by Leuenberger of the frequency of this condition in Basle are very striking. From 1901 to 1910 the population of the city included approximately 55,500 male workers, and the number of workers employed in the aniline factories was 840. During that period six workers in aniline dyes died as a result of tumour of the bladder. During the same period there were twelve deaths from the same affection among the rest of the male population. Six cases of tumour of the bladder were observed at the surgical clinic at Basle from 1861 to 1900 before the development of the chemical industry; from 1901 to 1910, after the development of the chemical industry, 16 cases of tumour of the bladder were seen; 10 of these occurred in aniline workers and 2 in dyers.

A large proportion of the tumours noticed have been malignant. They appear especially after the age of 40, and particularly in individuals who have been working in contact with the materials for many years. A large number of products, either singly or in association with others, have been held responsible by various observers. All the suspected products, such as aniline, toluidine, naphthylamine, etc., are amino compounds. Leuenberger enumerates the following as capable of provoking tumour growths: Safranine, dianisidine, dihydrothoxyline, Congo red and benzo purpurine. Benzidine and beta naphthylamine are considered particularly dangerous.

Experience proves that, while there is no immunity, predisposition plays a great part. There are many factors that favour poisoning—lack of cleanliness, malnutrition, alcoholism, and excesses of every kind. Workers new to the trade, and consequently working without precaution, with whom large skin surfaces come in contact with the

poisonous products, are specially liable. On the other hand, workers remaining a long time in the workshops are more exposed to the danger of introducing by deglutition the products floating in the air. Although the permeability of the skin by the products in question is remarkable, older workers, who take great care of the skin, yield a smaller number of cases of poisoning.

The poisonous products enter the body by various routes—aniline, which is volatile, by the respiratory organs; others by the alimentary canal and the skin and mucous membranes. At present it is not possible to say exactly which is the toxic substance that produces the growth of these tumours. The tumours are met with almost anywhere in the bladder, most often on the inferior segment and near the neck. They are said to have been rarely seen below the ureteral orifice. Profuse and dangerous haematuria is a common symptom. Carcinoma is met with, either as a primary tumour infiltrating the bladder wall or as a secondary development following a papilloma. At an early stage the tumours are frequently accompanied by cystitis and nephritis. Lymphatic metastases are found but visceral metastases are uncommon.

The provisional conclusions which the facts are considered to warrant are as follows:

1. There is a close connexion between the manipulation of certain amino-compound products and tumours of the bladder.
2. The number of cases of tumour of the bladder proved to have occurred among workers in contact with amino-compounds is small, and it must therefore be concluded that the individual factor plays a great part in the pathology of the disease.
3. Though no direct relation can be traced between their occurrence and the duration of employment, action of long duration is necessary to produce tumours of the bladder.
4. It is not possible to determine the substance capable of engendering tumours. It can only be said that the amino-compounds, and particularly benzidine and beta-naphthylamine are incriminated.
5. The same substance may produce either simple cystitis or benignant or malignant tumours.
6. Hygienic precautions, strictly applied for a few years, will ensure the diminution and even the disappearance of the disease.
7. It is therefore necessary in factories in which workers are exposed to the action of aromatic bases that hygienic precautions should be rigorously applied.
8. Meanwhile, it is desirable that the industries concerned should continue to carry on researches with a view to ascertaining the dangerous substance, and that the particulars of every case should be precisely recorded by a uniform method.

In the report now before us the importance of early diagnosis by cystoscopic examination is urged. Experience in Germany has shown that repeated cystoscopic examination in suspicious cases is welcomed by the workers when the danger of the disease is pointed out to them.

Kuchenbecker has elaborated a method of examining the urine to demonstrate the presence of amino-compounds; by the periodical examination of the urine of workers dealing with fuchsine, and particularly those preparing benzidine and naphthylamine the presence of the substances named has by this method been traced in large quantities among workers exposed to the inhalation of dust in the factories. The efficacy of the means of prevention adopted has been confirmed by such examination; the quantity of the products in the urine has been observed to diminish and even to disappear after their application.

The precautions taken in certain German factories producing amino-compounds during recent years are believed to have yielded good results. These may be summarized as follows:

Well-ventilated workrooms with extraction of vitiated air and introduction of fresh, and, if necessary, cooled air; rigorous cleanliness of floors and walls; absorption of dust.

Well-closed apparatus, including the apparatus for the mechanical transport of materials; local absorption of dusts and vapours.

Reducing working hours; adoption of shifts, in view of the fact that a very short stay in the incriminating section is sufficient to produce tumours.

Working clothes, always strictly clean, closed at the neck and wrists; gloves and shoes.

Daily bath; careful washing before going to the refectory or leaving the factory.

Medical examination of workers, both on engagement and periodically; selection of healthy workers; periodical instruction by the medical officer and director of the section. The periodical examination includes examination of urine as previously indicated.

Compulsory notification of haematuria and tumours of the bladder among workers in factories producing amino compounds.

Routine cystoscopic examination in cases presenting suspicious symptoms.

In this country regulations have been in force since the end of 1908 laying down the precautions to be observed in the manufacture of certain nitro- and amido-derivatives of benzene and the manufacture of explosives. They apply to dinitrobenzol, dinitrotoluol, trinitrotoluol, paranitrochlorbenzol, aniline oil and aniline hydrochloride. The regulations provide for the extraction of vapour from covered apparatus and for the removal of fumes from rooms by through ventilation by a fan or other efficient means. In crushing materials or filling cartridges with them, an efficient exhaust draught must be so arranged as to carry away the dust as near as possible to the point of origin. An employer must supply suitable overalls, which must be washed every week, or suits of working clothes, a room for changing, another for the storage of overalls, and a messroom. All persons handling the substances are to be supplied with india-rubber gloves, and a suitable scoop must be used in filling cartridges by hand. The workers are required to use the protective appliances, and to clean their hands before partaking of food. Every person employed must be examined by the certifying factory surgeon of the district once a month. The surgeon has power to suspend any person from work. These general regulations are based on the well recognized toxic character of these substances, and the risk of absorption through the skin and subsequent effect on the blood, and though they have no special reference to the prevention of tumour of the bladder are of a nature calculated to attain this end.

Mr. J. F. Dobson, surgeon to the Leeds General Infirmary, has been good enough to make some general inquiries in the North of England, where large dye factories have been established in recent years. At one large factory near Huddersfield the medical man who had had charge of the employees for some years stated that he had seen some cases of haematuria, but had looked upon them as of renal origin; so far as he knew, none of the cases had developed tumour, but none had been examined with the cystoscope. Mr. Dobson, after an examination of the records of the large number of cases of bladder tumour he has seen in recent years, tells us that he is unable to satisfy himself that such tumours occur more frequently in individuals employed in the dye industry than in others; at the same time, of the last two cases he has seen, one was employed in the manufacture of benzol and the other was a dyer. He points out, however, that the workers in the North of England have probably not yet been exposed to the poisons for a length of time sufficient to produce the lesion, and suggests that Kuchenbecker's test mentioned above might be of use in ascertaining whether the urinary condition is prevalent.

Papilloma of the bladder develops so slowly that the slight initial haematuria would not be regarded seriously either by the worker or the medical man if they were not aware of the danger. The evidence shows that tumours of the bladder due to this cause do not develop until the individual has been exposed to the action of the injurious compounds for many years. The condition can only be diagnosed at a stage when satisfactory treatment is possible if routine examination of cases presenting suspicious symptoms is carried out. This will involve the use of the cystoscope—not an easy instrument to manipulate. Early diagnosis is, Mr. Dobson points out, of extreme importance, for in its early stage papilloma of the bladder can be satisfactorily treated by endovesical diathermy; operation for papilloma gives less satisfactory results. Primary malignant disease of the bladder is very rarely suitable for operative treatment.

A NEW monthly journal, *The Japan Medical World* (Nippon-No-Ikai), has been founded by Dr. S. Tsachiya in Tokyo, with the assistance of many eminent members of the Japanese profession desirous of making medical progress in Japan better known. The journal, which is written in English, will contain original articles, notes of current Japanese literature, reports of medical societies, and medical news. The annual subscription is 6 dollars, post free. The offices are at No. 10 Omotejinbocho, Kanda, Tokyo.

British Medical Journal.

SATURDAY, APRIL 30TH, 1921.

A CONSTITUTIONAL PROBLEM.

A body one of whose two main objects is "to maintain the honour and interests of the medical profession" must find itself periodically under the necessity of modifying its constitution and machinery to meet the needs of the times. The British Medical Association, in its history of nearly ninety years, has never hesitated to make adjustments of this kind even when they entailed considerable departures from custom and tradition. Notably in 1903 radical changes were made in order to create smaller local units and to bring into existence a Representative Body which should be able to ascertain and formulate the desires of a profession organized on modern democratic lines.

The time has come to make possible another step, the necessity for which has arisen from the Empire-wide scope of the Association. Just as British colonies and dependencies have in the course of their growth demanded greater freedom in dealing with their own affairs and have brought about, with the consent and goodwill of the mother country, the necessary changes in their forms of government and their relations with the Home Government, so it has happened with the Branches of the Association in the great Dominions. Gradually, over a period of many years, changes desired by them have been effected by a liberal interpretation of the Articles and By-laws of the Association, and, with very few exceptions, the Central Council has always been able to meet their wishes for greater freedom. The overseas Branches have, in fact, almost unlimited autonomy. But there have been demands which the legal advisers of the Association have ruled could not be met by anything less than a radical revision of the constitution. For example, the right to hold property, to sue and be sued as separate entities, to provide medical defence facilities, and to invest and otherwise deal with money, have been held to be powers that could not legally be exercised by Branches as such. These difficulties can be and have been got over in the overseas communities, as well as in England, by the formation of trusts. That method is still available, but it is an indirect and somewhat cumbersome method. In order that the Branches in Australia, where the problem has arisen most acutely, should understand that no efforts would be spared to meet every legitimate demand on the Association, the Annual Representative Meeting at Cambridge last year approved the proposal that steps should be taken whereby any overseas Branch or collection of Branches feeling such a step to be necessary should be able to leave the Association, form themselves into a separate body with all the powers they desired, and affiliate themselves in their new form to the Association. In the consideration of this matter the Council was greatly aided by Dr. W. T. Hayward, C.M.G., formerly and now again Chairman of the Federal Committee of the British Medical Association in Australia, and Dr. H. S. Newland, C.B.E., D.S.O., of Adelaide, both of whom were in this country on military service.

The methods by which this new departure can be brought about were fully described in the SUPPLEMENT to the JOURNAL of March 5th last, and it will be for the Representative Body at Newcastle-upon-Tyne next July to accept or decline the new Articles and By-laws in which the proposals are embodied. They need and deserve the careful study of every member of the Association interested in the evolution of its constitution. They are, we know, receiving anxious consideration by the overseas Branches specially interested, and we are glad to learn that Australia is sending a special envoy to Newcastle in the person of Dr. R. H. Todd, the Honorary Secretary of the Australian Federal Committee, who has been very prominently concerned in the progress of the Association in Australia for many years. New Zealand is sending Dr. W. Irving of Christchurch to act in a like capacity for that Branch. Both are assured of a hearty welcome. The attitude of the Representative Body will, of course, be influenced greatly by the spokesmen from overseas.

But while the Association at home is making provision for such means of affiliation, it must not be supposed that it looks upon this as anything but a regrettable necessity. If, indeed, the overseas Branches should ultimately believe it to be a necessity. We are sure that all the home members would much rather preserve the present relationship if possible. It is for the overseas Branches to decide whether they really need this complete independence. If they can see their way we would much rather have them as Branches of the old Association than as a new Association, with another name, affiliated to the British Medical Association. We would rather have them as brothers than as cousins, but it is for them to decide.

There is another aspect of this question which the Representative Body will be called upon to consider. Is affiliation to be open to other Branches besides those overseas? The question has arisen in Ireland, where there has for some time been a desire on the part of the Branches of the British Medical Association and the Irish Medical Association to fuse themselves into one association which, while composed of both bodies, will be neither, but a new body which, it has been proposed, may affiliate itself to the British Medical Association. If the new Articles and By-laws are carried it would be open to the proposed new body to apply for, and for the Representative Body to receive it in, this new relationship. More than this, the resolutions carried at Cambridge contemplated the possible affiliation of bodies in this country formed to safeguard the interests of special sections of the profession, or even bodies not wholly medical but dealing with the interests of some allied profession. The new Articles and By-laws as set out in the SUPPLEMENT of March 5th make provision for all these developments, and it will be for the Divisions in the next few weeks to decide how widely they wish the door to be thrown open. The conditions on which affiliation is to be offered are to be decided in each particular case by the Representative Body itself. In the Annual Report of Council published in this week's SUPPLEMENT (pp 105-159), will be found a series of memoranda or rules setting out in skeleton form the kinds of agreement that might be made with any bodies admitted to affiliation. The whole subject is of great difficulty and delicacy: we hope we have said enough to convince members that they should study it thoroughly and make up their minds how far the new proposals are for the good of the Association as a whole, and therefore to be accepted.

PHYSIOLOGY AND CLINICAL MEDICINE
IN SHEFFIELD.

THE Panel Committee of Sheffield has given £1,000 to the University of Sheffield to promote the policy of bringing physiology into closer relation with the practice and teaching of clinical medicine. The new departure is interesting from both points of view—that of the University and that of the Panel Committee. The aim of the University authorities and of its medical faculty is to break down the barrier which has been allowed to grow up between physiological and clinical studies. Physiology derives directly from medicine, and it was necessary that the younger discipline should pursue its own way until it had reached a certain standard of accurate and established knowledge. It is apparent by many signs that this stage has been reached. An instance is afforded by recent work in dietetics, and especially as to vitamins, which has yielded important results on the border-line of physiology and pathology.

It will be remembered that a short time ago Dr. Edward Mellanby, a physiologist who had recently given much attention to vitamins, especially in connexion with rickets, was appointed professor of pharmacology in the University of Sheffield. At the same time the board of the Royal Infirmary, in order that the new professor and his department might not be divorced from clinical work, appointed him to a vacant post of honorary physician to that great teaching hospital. In pursuance of this policy of securing for the patients of the infirmary and the students of the medical faculty the benefits of expert physiological advice and teaching, the Board, with the consent of the University, also appointed Professor J. B. Leathes, M.B., F.R.S., the present incumbent of the chair of physiology, to be consultant physiologist to the Infirmary. Another development of the same policy is seen in the appointment, through a joint arrangement with the Royal Hospital and with the approval of the University, of Dr. Imrie to be full-time clinical physiologist to both hospitals. Dr. Imrie had previously been deputy professor of biochemistry at Toronto.

These appointments have vastly strengthened the medical work in the city, both on the educational and technical side, and by the generous assistance they have given to the Department of Pharmacology and its field laboratory the panel practitioners of Sheffield have not only afforded most valuable support to the University of their city but are helping research work which promises to yield fruitful results in therapeutics; it will be interesting to explain how it has come about that they are in a position to do so.

By the exercise of strict economy and the use of the voluntary labour of its members during the war years, the Panel Committee was able to save from its funds enough money to invest £1,000 in War Loan. It was felt at the time by the Committee that it was very necessary to have some accumulated funds for use in any acute emergency which might arise, and the fact that the Sheffield Panel Committee was financed by a purely voluntary scheme rendered this possible. When the financial situation was reviewed at the beginning of this year, it was seen that the economies had resulted in a considerable surplus; so much so that the voluntary levy could be suspended for at least six months, and that a sum of about £1,000 could be disposed of. The matter was fully considered at several meetings of the Panel Committee, and legal opinion was taken. Finally a meeting of practitioners on the panel was called, and at it a resolution was passed directing that War Stock to the amount

mentioned should be transferred to the University with a request that it should be earmarked for the equipment of a Field Research Laboratory in the Department of Pharmacology under Professor Mellanby. This has now been done.

Professor Mellanby's department will consist of a laboratory at the University, and of a fully equipped field laboratory for experimental work, on the lines of his field laboratory at Cambridge, which many members visited during the Annual Meeting last year. Professor Mellanby's work on rickets in relation to fats and vitamins has, as is well known, revealed many hitherto unsuspected aspects of this vexed problem; whilst Mrs. Mellanby's brilliant proof that the problem of dental caries is largely a matter of biochemistry, rather than of mechanics or bacteriology, is closely related to her husband's work. Professor Mellanby's association with clinical medicine has already produced some other results which promise to bear valuable fruit, for we are told that, in a preliminary communication recently made to the Physiological Society, he was able to announce that if patients with Graves's disease were put on to a relatively low diet, almost free from fat, with small doses of cod-liver oil and potassium iodide, they gained weight rapidly and the symptoms were ameliorated.

The action of the Sheffield Panel Committee may help the public to an understanding of the medical point of view, about which there is a good deal of misapprehension. The representatives of Approved Societies too often seem to believe that the medical profession is always thinking of schemes to get higher rates of pay, and medical correspondents of newspapers that it is ready to be the dupe of anyone who with sufficient drum-beating proclaims a new specific remedy for some intractable disease, or alternatively to be superciliously sceptical. The gift to the Pharmacological Department of the University of Sheffield is evidence of the real orientation of medical opinion towards the discovery of fundamental facts as to the functions of the organs of the body, and the causes, prevention and remedy of their disorders.

SECURITY OF TENURE FOR PUBLIC HEALTH
OFFICERS.

THE efforts which have been made by the British Medical Association for many years past to obtain security against unfair dismissal are at length bearing fruit. After a deputation to the Government in June, 1914, a promise was made by the then President of the Local Government Board, Mr. Herbert Samuel, that if it proved within its power to do so the Board would make an Order giving security of tenure to whole-time medical officers of health and inspectors of nuisances. The issuing of this Order was deferred owing to the disorganization of the medical services of local authorities due to the war, but in May, 1920, Dr. Addison, upon being reminded of Mr. Samuel's promise, stated that he would have the Order proceeded with, and would go as far as he could in giving security to whole-time medical officers of health and inspectors of nuisances. The Order, dated April 12th, 1921, has now been issued. It applies to whole-time medical officers of health and sanitary inspectors (inspectors of nuisances) appointed by the council of a county borough or county district, or by a port sanitary authority. The council of a county district includes a municipal corporation or an urban or rural district council. Appointments of these officials made after May 1st next will be without limit of time, after a probationary period of twelve months, at the expiration of which the appointment must be confirmed by the Minister of Health. The definition of a whole-time officer is one who is required by the terms

of his appointment to devote the whole of his time to the duties of his office or of any other office or offices held by him under any local or other public authority. The effect of the Order is that all whole-time medical officers of health will have security of tenure, except those appointed before May 1st, 1921. In order to put them in the same position as their colleagues, Sir Philip Magnus, at the instigation of the Association, introduced the Public Health (Officers) Bill in the House of Commons on April 12th, and he had the good fortune to secure its second reading on April 14th.

THE UNIVERSITY OF BRISTOL

The University of Bristol, like most of the other English universities, is making a public appeal for general endowment—a course it is well entitled to take in view of the substantial support the University is receiving from local education authorities in the West of England. In explaining recently the grounds of the appeal, the Vice-Chancellor, Sir Isambard Owen, D.C.L., M.D., made it plain that the needs of the Faculty of Medicine are to be accorded a distinctive place in it, the endowment of professorships in the faculty being put forward as an urgent matter. The Bristol Medical School, now incorporated in the University, has a long and honourable history, illustrated by many distinguished names; and under the aegis of the University (founded in 1909) has achieved a reputation which we hope will make a powerful appeal to the public spirit and generosity of the West of England. The number of medical students in Bristol is at present 155, and the faculty includes also a flourishing school of dental surgery, with 75 students.

SECRET REMEDIES AND THE GERMAN MEDICAL PRESS.

It would appear that the sale of quack remedies has greatly increased in Germany under the new order, and many bitter things are said in the medical journals about democracy in its relation to the control of unqualified practitioners and their remedies. Three periods during which the fortunes of the quack oscillated violently can, it is said, be distinguished. In the first, the pre-war period, there was a neck-and-neck race between the enterprising quack and the paternal Government, which, by new regulations, was constantly heading off new devices for exploiting the credulous. At one stage in this period it was calculated that of seventy-five secret remedies analysed, as many as forty-eight were directly dangerous to life, and another eleven were calculated to be injurious. In the year 1898-99, the turnover of secret remedies in Germany amounted to 30 million marks, and 500,000 kilograms of secret remedies were imported yearly.¹ In the second period, which corresponds with the great war, the lot of the vendor of quack remedies was hard. Though he might attempt to distribute his goods among the troops as more or less authorized gifts from Hindenburg or Zeppelin, his campaign was soon cut short by the military authorities, whose regulations ultimately became very stringent. The third, or post-war period, would seem to have afforded brilliant openings for nimble-witted adventurers, who have found in the sudden political change unrivalled opportunities for avoiding punishment. Recently a circular signed by Professors Heffter, Klenperer, Lennhoff, and Schwalbe, and the chairman, Dr. Herzau, has been addressed by the Association of the German Medical Press to the editors of medical periodicals, pointing out that the impudence of advertisements of all kinds of quack remedies is increasing, and asking the editors that they should arrange with the publishers to have a controlling share in the acceptance or refusal of advertisements, if they already do not possess such power. The manifesto recommends that only such advertisements of remedies should be accepted as state the

composition of the remedy, and that advertisements should on principle be refused which appear in the daily press and in form and matter are bombastic, extravagant, untrue, or misleading.

ACUTE BENIGN LYMPHOBLASTOSIS.

DISEASES of the lymphatic glands present a number of problems awaiting solution, and among these the influence of acute adenitis on the blood picture is of considerable interest. The tendency of glandular inflammation and irritation to produce a lymphocytosis is fully recognized, but the degree of this reaction may vary considerably, and in some instances the blood count may strongly suggest acute lymphoid leukaemia, and indeed doubt as to the correctness of this diagnosis may only arise when the patient recovers. In glandular fever, originally described in 1839 and lately rather forgotten, though Drs. H. L. Tidy and Morley recently gave a full clinical account of it in our columns,² there are very few blood counts available, but in some examples of acute lymphadenitis the diagnosis from acute lymphoid leukaemia in an early aleukaemic stage—that is, with little increase in the total white count—may cause much anxiety. Thus T. P. Sprunt and F. A. Evans recently described, under the name of infectious mononucleosis, a fairly definite group of 6 cases with fever, enlarged glands, a leucocytosis up to 20,000 per c.mm., a slight increase in the large mononuclear-transitional cells, and many pathological lymphoid forms.³ A very similar, if not identical, series of cases has just been recorded by W. A. Bloodorn and J. E. Houghton⁴ at the United States Naval Hospital, Annapolis, Maryland, as acute benign lymphoblastosis; all the four patients were young adults and showed febrile enlargement of the lymphatic glands, particularly the cervical and submaxillary, and sometimes of the spleen, usually after infection of the tonsils or upper respiratory tract; leucocytosis was not constant, but the striking change was a mononuclear increase with lymphoblasts predominating, and often the presence of cells with the clover-leaf or bilobed Rieder nucleus. Three out of the four cases showed Vincent's organisms in throat smears taken during the acute phase, but examination of several cases of Vincent's angina proved that lymphoblasts are not a common feature in this form of infection. All the patients recovered, but the differentiation of this condition from acute lymphoid leukaemia may be very difficult; the absence of degenerated and fragile cells in the blood smears, the early fall of temperature, the mild course, and the absence of haemorrhages and of high leucocyte counts, are the distinguishing features.

EFFECTS OF CARBON MONOXIDE ON THE EYE.

THE effects of carbon monoxide upon the eye, about which very little can be found in the textbooks of ophthalmology, form the basis of an interesting paper by W. H. Wilmer of Washington in the *American Journal of Ophthalmology* for February, 1921. He gives a general survey of the subject and deals with the nutritional effects of carbon monoxide poisoning, as well as the eye complications. The paper reads like a ghost story in places, and certainly throws light on the question of haunted houses. Wilmer gives the notes of two cases: in the first a whole family was subjected to the slow poisonous effects of the gas fumes escaping from a faultily constructed furnace into the house instead of going up the chimney; the member of the family who suffered most was a small boy aged 4 years. The general symptoms were noticed by all members of the household, and consisted in listlessness, delusions, and hallucinations. Wilmer saw the little boy some four years after he had been taken from the poisoned house; his general health had been much upset, he was anaemic, and suffered from gastric

⁴ *Deut. med. Woch.*, January 20th, 1921.

disturbances; though intelligent for his age, he was slow in reading. The chief change found was a contraction of the visual fields. The fundus did not present any obvious abnormality, but the disc is stated to have been high-coloured; charts of the fields of vision taken at this time show a general contraction down to within 20 degrees of the fixation point. As time went by this contraction for white gradually improved, and after two years the field for white was shown to be very nearly full, but an enlargement of the blind spot and a large paracentral scotoma remained. The second case occurred in a man, aged 35, who was at work in a closed room removing paint from a mantelpiece by means of a gasoline torch. After about two hours' work faintness, giddiness, nausea, and headache came on, but quickly disappeared on ceasing work, when he noticed some mistiness of sight. On resuming work a similar train of symptoms occurred, but the visual defect, which had quickly cleared up after the first bout, now persisted. The man saw several oculists, who diagnosed optic atrophy; the fields show a slight general contraction for white, and it is stated that the colour sense is defective, while central vision is reduced. We agree with the author as to the importance of having household furnaces of this kind, as well as all gas fixtures, properly inspected in order to obviate such domestic calamities; in Wilmer's first case it appears that the small boy was not far off the point of death when he was taken from the poisoned house. It would be well to bear this cause in mind when dealing with unexplained cases of optic atrophy.

BILHARZIASIS AND ITS TREATMENT.

At the annual meeting of the British Medical Association at Cambridge last year Dr. P. Manson-Bahr, as reported in the *Journal* on August 14th, p. 235, related some encouraging experiences he had had in the treatment of human trypanosomiasis and kala-azar by intravenous injections of the acetyl-para-aminophenyl stibiate of soda, called for convenience "stibenyl" by the manufacturers, Messrs. Allen and Hanburys. It contains 34.3 per cent. of antimony. He found, however, that this preparation was of no value in bilharziasis, and a patient on whom it had no effect was cured of the disease after 16 grains of tartar emetic. The toxicity of tartar emetic is a great disadvantage, as extremely small doses only can be tolerated by man, and the treatment is necessarily protracted. Dr. F. G. Cawston, of Durban, who for some considerable time has been carrying on researches into the treatment of bilharziasis and allied conditions, has therefore sought to obtain a therapeutic agent of less toxicity than tartar emetic, for which purpose he received last year a grant from the British Medical Association on the advice of the Science Committee. Articles by Dr. Cawston have been published in our columns (November 20th, 1915; July 29th, 1916) in which he stated that the best treatment of bilharziasis at that time was by means of diuretics and urinary antiseptics; hexamine, which is a slight diuretic as well as a powerful urinary antiseptic, being considered the most valuable. He pointed out also that too much reliance should not be placed on remedies that had been recommended as cures unless microscopical examination of the urine of the persons said to have been cured had been made. We have now received a communication from Dr. Cawston containing the results of his tests of the efficacy in the treatment of bilharziasis of two new and untried preparations of antimony, which like stibenyl have been made by Messrs. Allen and Hanburys—acetyl para-phenylene diamine antimony tartrate (antimony 26 per cent.) and para-phenylene diamine antimony tartrate (antimony 28 per cent.). Dr. A. Wallace, of Broken Hill, tested for Dr. Cawston the effect of stibenyl on a case of trypanosomiasis, but did not consider that it acted so well as tartar emetic, so, in view of the opinion also of Dr. Manson-Bahr, Dr. Cawston did not test that

preparation on bilharziasis. The other two preparations he did not find less toxic than an equivalent quantity of potassium tartrate of antimony (tartar emetic), but the first of the two was in one case at least effective in curing bilharzia disease of long standing. As antimonyl sodium tartrate is definitely less toxic than either of the two preparations, and is apparently equally effective, Dr. Cawston does not consider there is any advantage in employing the new preparations of antimony on further cases of bilharziasis in South Africa.

MIDHURST SANATORIUM.

THE report for 1920 of the King Edward VII Sanatorium, Midhurst, of which Dr. H. O. Blanford is superintendent, contains many points of interest. Treatment by graduated labour, combined with adequate rest, was more systematized during the year, the work being carried out in the grounds and gardens of the institution; the treatment had a good effect both on the physical and mental conditions of the patients. In April, 1920, an x-ray department was opened, which has already proved of great assistance in the diagnosis of indefinite cases. In the pathological laboratory, which was reopened after having been closed during the war, a considerable amount of research work has been carried out. The routine examinations of sputum has been modified to some extent; positive cases are examined less frequently, and more attention is being devoted to repeated examinations of negative cases. This procedure was adopted owing to the fact that a considerable number of negative tests were found to be requisite to justify the presumption that tubercle bacilli were no longer present. In most of the positive cases the bacilli were usually easily found, but repeated examinations were necessary in some cases before their presence could be demonstrated. Up to the present both sedimentation methods and guinea-pig inoculation have proved negative in cases in which tubercle bacilli were not found after repeated careful examination of films stained by the Ziehl-Neelsen method. An investigation was carried out to ascertain whether Pfeiffer's bacillus commonly infected the lungs of tuberculous patients, and whether phthisical patients were commonly chronic carriers of the bacillus. In only one case, however, was the impression given that Pfeiffer's bacillus was playing a part different from that of the other apparently innocuous organisms usually found in the respiratory tract. An investigation is being carried out also on the acid-fastness of tubercle bacilli, and it is hoped to establish definite figures as to the acid-fastness of tubercle bacilli which will serve as a basis for comparison of the various decolorizers; they will also serve as a basis for an investigation upon the variability of acid-fastness in different strains of tubercle bacilli found in the sputum. Statistics are given of the 275 cases discharged from the sanatorium during the year, which show the value of the early recognition and treatment of pulmonary tuberculosis. Excluding one patient in whom no definite evidence of disease was found, the condition on discharge was as follows: of 79 slight cases in 50 the disease was arrested, 21 were "much improved," 7 were "improved," and one was "stationary or worse"; of 89 cases in which the disease was more extensive than in the first group, but affected at most the whole of one lobe, the note in 21 was "disease arrested," 51 were "much improved," 15 "improved," and 2 were "stationary or worse"; but of the 106 more severe cases, including all those with considerable cavities, 4 only had "disease arrested," 44 were "much improved," 39 were "improved," and 19 were "stationary or worse." Sir StClair Thomson examined 268 cases laryngoscopically, and in 32 of these local lesions were found; 25 were in the group of advanced disease. In regard to prognosis the statistics of ultimate results are rather striking. The table in which are grouped all cases discharged since 1906 in the sputum of which tubercle bacilli were demonstrated in the

sanatorium, shows that while after five years the number alive was only between one third and one half of the original number discharged, yet after ten years the number of deaths had been very little, if at all, increased.

GOATS AND GOAT'S MILK.

WHILE all the world comes to Britain to buy horses, bulls, sheep, and pigs, comparatively little interest has until recently been taken in goats. Their number in proportion to the population has been very small as compared with such countries as Switzerland, where goat-breeding has been studied for centuries. There has, however, long been a band of goat-keepers in this country, faithful though small, and information as to the choice of goats and the method of keeping them was available when, owing to the high price of milk and milk products during the war, public attention was turned to possible alternatives. Another circumstance which may lead to greater use of the goat in this country is the increase in the number of small holdings which is taking place in some parts of Great Britain, and especially, perhaps, in Wales. It has always been difficult for the small holder to get cow's milk; at the best he may have to send a long way for it, and at the worst none may be available, all being sent away to towns or converted into butter or cheese. For the small holder the goat is the ideal milk-yielding animal, and if skilfully managed is easy and economical to keep. It is true that to the unaccustomed palate the flavour of goat's milk is less agreeable than that of cow's milk, and, owing to its white colour, it has not the creamy rich appearance of cow's milk. Notwithstanding the colour, the percentage of fat in goat's milk is about the same as in cow's milk. We cannot agree with those enthusiasts who state that the goat is immune from tuberculosis, but it seems to be true that goats rarely suffer from that disease. It has also been stated that the milk of the goat is more nearly similar to mother's milk than the milk of the cow; but it differs so slightly from cow's milk that it has no advantage as a food for infants from that particular point of view. Yet the milk of the goat has valuable qualities, and goat-keeping and goat-breeding deserve every encouragement in this country. In this direction much useful spadework has been done for some years, and is being done to-day, by the British Goat Society, which has just published its first *Year Book*.¹ In this are included a large number of articles dealing with the goat, goat-breeding, and milk production. Prospective goat-keepers and goat-breeders will find the volume full of information, and it is well illustrated. The *Year Book* has been edited by the honorary secretary of the society, Mr. T. W. Palmer, and is published from the office at 5, Fenchurch Street, E.C.

BENVENUTO CELLINI'S MEDICAL EXPERIENCES.

CLOSELY allied to the psychological interest aroused by the history and trials of detected criminals is that derived from the candid confessions and diaries of J. J. Rousseau, Samuel Pepys, and Benvenuto Cellini. The last, though a thorough-paced rogue, has long had a fascination for the general reader and has been fortunate in his English biographers—John Addington Symonds and Augustin Birrell. Cellini (1500-1571) lived in eventful and lawless times, and as a highly artistic designer of jewellery and metal work played a prominent part in the Renaissance. During this period of the reformation and the revival of learning, medical practice was still hand-in-hand with quackery and superstition; the great epidemic of syphilis extended to Italy by 1494, and poisoning was a fine art in that country. It is therefore interesting to glance at Benvenuto Cellini's impressions and experiences of medicine as recently set forth by Dr. Jacob Rosen-

bloom,¹ of New York, and to compare and supplement them with Sir D'Arcy Power's² paper on the same subject written in 1893. Cellini had plague at the age of 23, malaria more than once, and on one of these occasions drank freely of water against medical advice and promptly improved; he describes an illness lasting two months, and ascribed to the bad air of Pisa, which may have been enteric fever; he was the victim of gont in his later years, and had several surgical accidents, such as fracture of the leg and a splinter of steel in the eye. But perhaps the most interesting of his remarks are on the subject of his attack of syphilis—or as it was then called in Italy, the French disease—which remained dormant for four months and then suddenly broke out all over his body. After following for some time medical advice without any benefit, he took guaiac (introduced from America about the year 1508) against the orders of the first physicians in Rome, and after fifty days was "cured and as sound as a fish in water." But from exposure he fell into a slow (syphilitic) fever, and in spite of the medical dictum that if he took guaiac with fever on him he would be dead in a week, he disobeyed and was well in four days' time. Later on he had a painful inflammation of the eyes, cured by a simple eyewash prescribed by the Pope; this is considered by Rosenbloom to have been a functional affection, whereas Sir D'Arcy Power thinks it was iritis. The practice of mercurial fumigation and inunction carried out by Giacomo da Carpi, who amassed a large fortune thereby, is mentioned by Cellini, with the sneer that the so called French disease is very partial to priests and especially to the richest of them. He alleges that at least three attempts were made to poison him; in one pounded diamond was to be administered in his food, with the object of setting up acute enteritis in the way that pounded glass acts, but the man entrusted with the grinding substituted a soft stone—a greenish beryl—so enriching himself and incidentally, as Cellini believed, saving him from a painful death. When he was about 48, corrosive sublimate, or as Power suggests, arsenic, was put in his sauce and caused acute colitis, but, to quote his own words, "the poison worked so well that whereas, before I took it, I had but perhaps three or four years to live, I verily now believe that it has helped me more than twenty years by bettering my constitution." It would indeed be an irony of fate if an attempted criminal poisoning really benefited the intended victim by curing an existing disease, but Cellini's conclusions are often based on very insecure grounds. His comments on his numerous medical advisers are, as a rule, highly critical.

THE STATISTICS OF TYPHOID VACCINATION.

REFERENCE was incidentally made a short time ago to French statistics which it was thought showed the value of antityphoid vaccination from an unexpected angle. The evidence was presented by Professor Chauffard to the Académie de Médecine, and the argument was so ingenious that it is worth while to reproduce it. He ascertained the age and sex incidence of the disease at his clinic at the St. Antoine Hospital (Paris) before and after the war. During the years 1912-13 there were 11 men and 42 women, the mean age being 24 for the former and 27 for the latter. Under the age of 20 the percentage was 27.5 for men and 19 for women; after 20 years of age it was 72.5 for men and 81 for women. During the years 1918-19-20 there were 10 cases in men and 23 women. For the latter the mean age remained at 27, and the percentage under 20 years was 24.5, while after 20 it was 75.5. These proportions are virtually the same as in the pre-war statistics. But on the male side things have greatly changed, for while the mean age was 17.5 years, the percentage under 20 years of age was 90, and after 20 only 10. As a matter of fact all the male typhoid patients

¹ *The British Goat Society's Year Book for 1921*. Price 1s. 3d. 5, Fenchurch Street, London, E.C.3.

² J. Rosenbloom, *Ann. Med. History*, New York, 1919, ii, 342-366. (Published 1920.)

³ D'Arcy Power, *Quart. Med. Journ.*, Sheffield, 1893, vi, 199-218.

in his clinic, with the exception of a man of 45 taken prisoner early in the war and unvaccinated, were between 16 and 18 years of age. The salient fact, then, is that there were no male typhoid patients except the very young who, not having been in the army, had not been vaccinated, while the female figures remained unchanged. This, Professor Chaffard contended, is an argument for applying this protective measure on a large scale among the civil population—a proposal which is receiving attention in France at the present time.

The King has been pleased to approve that the honour of knighthood be conferred upon Dr. James Craig. Sir James Craig, who was elected President of the Royal College of Physicians of Ireland in October, 1919, is King's Professor of the Practice of Medicine in the School of Physic, Trinity College, Dublin, Physician to Sir Patrick Dun's Hospital, and Physician in Ordinary to the Lord Lieutenant. He was at one time President of the Leinster Branch of the British Medical Association, and is a member of the Irish Committee of the Association.

We regret to announce the death, on April 23rd, of Mr. Henry Edward Juler, F.R.C.S., consulting ophthalmic surgeon to St. Mary's Hospital, London.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Budget.

THE budget statement made by Mr. Chamberlain (for Sir Robert Horne, the new Chancellor of the Exchequer), on April 25th, had no surprise except the announcement of the National War Bonds conversion scheme whereby such loans maturing in the next five years may be funded on terms which appear to be advantageous to investors.

The balance sheet for 1920-21 showed an actual revenue of £1,425,985,000, against an estimate of £1,418,300,000, and an actual expenditure of £1,195,428,000, against an estimate of £1,184,182,000, thus affording a surplus of £230,557,900, which, with sums statutorily provided for debt reduction and Exchequer balances, gave a total sum of £259,500,000 for debt reduction within the year. The actual reduction was less by £3,000,000, owing to the influence of the exchanges in the redemption of foreign debt.

Under a change now made for the first time, the estimates for 1921-22 are divided into ordinary and extraordinary accounts. The ordinary revenue is forecasted to be £1,058,150,000, and the expenditure £974,023,000, leaving a surplus of £84,127,000, which, however, is subject to expenditure and losses due to the coal strike. The extraordinary receipts and expenditure accounts show an estimated revenue of £158,500,000 from the realization of war assets and a debt of £65,705,000 for liquidation of war commitments, giving a surplus of £92,795,000, subject to a liability on termination of railway agreements. The full surplus, subject to these two liabilities, is thus put at £176,922,000. Mr. Chamberlain reckons that there may be an ultimate surplus of £80,000,000 for the reduction of the National Debt; which, with sinking fund allowances, may afford a total cash provision of £103,500,000 for this purpose, which is very different from the sum of £259,500,000 in the year just ended.

These figures are based on the maintenance of the taxation of last year in all respects, save that the Excess Profits Duty is abolished, and that the higher charges on cigars and sparkling wines, having proved unproductive, are ended. The surtax on cigars is abandoned; and instead of 7s. per gallon tax and 33½ per cent. *ad valorem* duty on sparkling wines, the duty is made 15s. per gallon.

In connexion with the income tax, Mr. Chamberlain referred to the fact that a number of claims were being received under provisions which operated to relieve falling incomes during the war; it was clear that the intention of Parliament last year was to cancel those provisions for 1920-21 and future years, and his advisers were of opinion that that intention had been effected; but, to put the matter beyond doubt and to dispose of it quickly, it was proposed to insert declaratory provisions in this year's Finance Act to clear up the questions that were being raised.

It should be noted that the estimates for the current year (1921-22) include £120,000,000 to come from arrears of Excess Profits Duty. Mr. Chamberlain stated that the assessment standing amounts to £300,000,000, and a large addition has to be made; but, on the other side, there will have to be allowances for adjustments and relief, and that is why the estimate for the current year is comparatively small. A further sum will be available under this heading next year, but this will be very much less. Mr. Chamberlain added significantly he could not expect that the ordinary revenue for next year, 1922-23, would be more than £950,000,000; and the Chancellor of the Exchequer is taking steps for further retrenchment by Government departments next year.

In the course of the debate some doubt was expressed by several private members whether the estimate for revenue was not sanguine. It has to be remembered, however, as regards income-tax yield that the returns on business are taken on a three-years' average; and there the Chancellor of the Exchequer, whatever the depression in the past year, will be greatly helped by the figures of the two preceding years in assessing his demand. But that fact will not assist taxpayers in finding the requisite money, and the burden for them will be serious.

Tuberculosis Bill.

Measure through Grand Committee.

The Public Health (Tuberculosis) Bill was taken in Grand Committee on April 22nd. Sir Watson Rutherford was in the chair, and about forty members were present. The first discussion took place on Clause 1, the text of which was as follows:

(1) Where the council of any county or county borough has, before the passing of this Act, made arrangements for the treatment of persons suffering from tuberculosis (including persons insured under the National Health Insurance Acts, 1911 to 1920) at or in dispensaries, sanatoria, and other institutions in accordance with a scheme or under an agreement approved by the Local Government Board, the Minister of Health, or the Welsh Insurance Commissioners, as the case may be, that council shall, for the purposes of this Act, be deemed to have made adequate arrangement for the treatment of tuberculosis so long as such scheme or agreement, with such modifications, if any, as the Minister may on the application of the council from time to time approve, continues in operation.

(2) Where the council of any county or county borough fails to make adequate arrangements for the treatment of tuberculosis at or in dispensaries, sanatoria, and other institutions approved by the Minister, the Minister may, after giving the council an opportunity of being heard, make such arrangements as he may think necessary for the purpose of such treatment.

Any expenses incurred by the Minister in arranging for such treatment may be paid in the first instance by the Minister out of moneys provided by Parliament, and the amount of any expenses certified by the Minister to have been so incurred shall be paid to the Minister on demand by the council and shall be recoverable as a debt due to the Crown.

Mr. Grundy proposed in Subsection (1) to leave out the word "where" and to insert "it shall be the duty of." As the clause stood it appeared to him that schemes already approved, whether adequate or inadequate, would be deemed quite sufficient, and he urged that there ought to be a review of all these schemes, and especially of those with respect to county boroughs. The amount of rate levied in the county boroughs varied from a farthing to fourpence in the £.

Sir Alfred Mond said it was impossible to accept the amendment, as it would change entirely the drafting arrangement of the bill without adding anything very material. The arrangements of the county and county borough councils were not continued under the clause. The schemes were considered adequate so long as they were satisfactory. Subsection (2) covered materially the point of the amendment. The bill was the result of very careful and lengthy negotiations with the councils and its passage into law at the earliest possible moment was of urgent importance. Sanatorium benefit expired at the end of a month. It was impossible to accept in Committee an amendment which changed entirely the character of an agreed bill and did not forward matters, but would really make obscure what was now clearer.

Mr. R. Richardson regretted that the Minister would not accept the amendment. It was known to many administering the measures with regard to tuberculosis that up to now the minimum has been aimed at. He believed that money spent by authorities to do the minimum, so that they might say they were doing something, was wasted money. Without such power of review it would be very hard for the Ministry of Health to ask councils whose measures had been approved to do more than they had already done. Yet the experience of those connected with National Insurance and friendly societies was that before anything could be done in 50 per cent. of the cases the disease had proved fatal.

Sir H. Nield, on behalf of the Middlesex County Council and the County Councils Association, supported the bill as it stood. This was not the time to suggest to local authorities that they must spend more and more rates.

Mr. Thomson challenged Sir A. Mond's assertion that the bill should be taken as agreed because the local authorities had generally accepted it through their associations. He submitted that Insurance Committees and their Sanatorium Committees

National Health Insurance: Medical Benefit.—In reply to Sir Croydon Marks, Sir A. Mond said that the number of persons in England and Wales entitled to medical benefit under National

Health Insurance was approximately 12,750,000. Figures were not available of the number of insured persons actually receiving (a) medical treatment, (b) cash benefits in particular weeks. The total number of insured persons in England and Wales who were receiving treatment for tuberculosis in sanatoriums or other institutions was 8,922 on March 1st, 1921, and 8,754 on March 1st, 1920. The number of non-insured persons receiving such treatment on those dates was not available, but the number of beds available for non-insured and insured persons in approved institutions for the treatment of tuberculosis was 17,894 on March 1st, 1921, and 16,432 on March 1st, 1920.

University Grants for Scotland and Wales.—Sir R. Thomas asked, on April 19th, whether the President of the Board of Education was aware that the total increase in the annual grants to the Scottish universities for the year 1920-21 amounted to £81,000, and in the case of the three constituent colleges of the University of Wales to £16,000, and that, taking population as the basis of comparison, the increase in the case of Scotland was about 96 per cent., and in the case of Wales only 44 per cent.; and that in the case of Scotland the increase was unconditional, but in the case of Wales was an advance by the Treasury equivalent to a penny rate to be raised by the Welsh county councils; whether the Minister was aware that the university building grant in the case of Scotland was £248,000, and in the case of Wales £50,000, and that on population basis Wales was entitled to £89,200. Sir H. Craik asked whether the Minister for Education knew that the grants for the Scottish universities were to a very large extent statutory grants made in return for revenues belonging to the university and commuted under the Act. Lieutenant Commander Young replied that the increased grants were as stated, but a further sum of about £24,500 was due to the University of Wales, under the pound for pound arrangement, and would be paid on certification of the levy of the penny rate. The percentage increase over the previous year would then be: Scotland 96 per cent. and Wales 111 per cent. He was not sure Sir R. Thomas calculated the university building grant in Scotland as £248,000. No building grants had been made since the present University Grants Committee was appointed in 1919, and returns relating to earlier dates suggested a figure very much lower. As regards the suggestion of injustice to Wales, Lieutenant Commander Young said the assistance given appeared to be, if anything, more favourable than that given to Scotland. On the basis of the number of full-time students in residence, the grant for students in Wales was more than twice the Scottish figure.

The Registration of Nurses.—Mr. Grundy asked the Minister of Health, on April 19th, whether the important work of the General Nursing Council for England and Wales was in charge of a junior official of the Ministry of Health who knew nothing of medicine or nursing, and who could not appreciate professional points which had to be adjusted between the three statutory authorities in the United Kingdom; and whether he would take whatever steps were necessary to avoid rules being forced on the English Council which might result in the boycott of the register when opened. Sir Alfred Mond replied that Mr. Grundy was misinformed. Questions relating to nurses' registration were dealt with in the ordinary course of departmental business by administrative and medical officers of appropriate standing, and subject to the Minister's instructions. The General Nursing Council had only been required to bring them such alterations in the rules as were necessary to bring them into conformity with the Act or to give effect to the intention of Parliament. Mr. F. Hall, on April 20th, asked whether the English Act for the registration of nurses, passed in December, 1919, had not been carried into effect, and that efforts were being made departmentally to coerce the General Nursing Council of England and Wales to agree to provisions incorporated in the rules framed under the Scottish Act of which the Council did not approve; and whether such provisions would have the effect of reducing its authority in certain important directions to that of a recording body under the Scottish Board of Health. Sir A. Mond said that Mr. Hall was under a misapprehension. The General Nursing Council was under a rule purporting to give them a discretion to refuse to admit to their register nurses already on the Scottish and Irish Registers. He was advised on the highest authority that this was *ultra vires*, and he was bound to ask the Council to amend the rule; subject to the submission of an amended rule affording reciprocity provisions he would sanction at once the rules for the admission of existing nurses.

Medical Needs of the Auxiliary Division in Ireland.—The Irish Attorney-General stated, on April 14th, that the Auxiliary Division was not provided with its own special medical transport and that ambulance and other necessities of medical equipment were borrowed from the regular forces, and when required, an arrangement which the authorities deemed satisfactory. Lieut.-Colonel W. Guinness asked whether notice had been taken of the sufferings of many of the auxiliaries who had been wounded in the Longford Camp, and whether the Chief Secretary would consult the Director of Army Medical Services in Ireland as to what steps had been taken so that men suffering from grievous wounds should not be left lying in the open without proper attention, as had often happened. Mr. Dennis Henry promised to bring the matter before the authorities. Earl Winterton said that at Longford Camp men had been left lying about for twenty-four hours, because no proper provision was made for them, and because it was not the duty of the army authorities to convey them to the hospital. Mr. Henry repeated that the matter was receiving attention.

Pensions Appeal Tribunals.—Sir Gordon Hewart, in reply to Mr. T. Griffiths, said that the Act of 1919 provided that a Pensions Appeal Tribunal should consist of one legal representative, a disabled officer or a disabled man, and a duly qualified medical practitioner. He was informed that an ex-commissioned officer never sat as service member on a tribunal to hear appeals of ex-service men and non-commissioned officers. Representations as to the desirability of including industrial women in the membership had been received, but it was not considered desirable to increase the personnel as suggested.

Permanent Pensions for Disabled Men.—Mr. McLean asked, on April 14th, whether the Pensions Minister had received any representation from any Local Pensions Committee to the effect that when a man had been under treatment for two years he should be granted a permanent pension (or sooner) if the decision of the medical man was that the disability or disease was likely to be permanent. Mr. Macpherson said that under existing practice award of pension was made permanent when the medical advisers of the Department were able to certify that the disablement had reached the final and stationary condition. Of late he had received many representations in favour of the award of permanent pensions within specified periods, and he was now having the question thoroughly examined. The matter was one of great complexity, which required very careful consideration in the interests both of the State and of the disabled men.

Disability Pensions.—Sir T. Bramsdon asked, on April 22nd, whether the Pensions Minister was aware that, up to June, 1917, many disabilities were looked upon as not attributable to the service, but subsequently medical opinion modified, and these disabilities were now considered in some cases to be attributable to or aggravated by the service, and whether, as a matter of equitable treatment, all pensions could be reviewed according to the present policy of the Ministry. Mr. Macpherson said that pensions appeal tribunals had been established to deal with appeals against the decision that a man's disability was neither caused nor aggravated by his service. Any man invalided in the earlier years of the war with a disability held to be not attributable to service, and who had not yet appealed, might now put forward his claim through the Local Pensions Committee, and it would be reconsidered by the Ministry before submission to the tribunal.

Pensions Appeals Delay.—Sir Gordon Hewart, in answer to Mr. Davies, on April 21st, said that there were about 8,500 appeals waiting to be dealt with by the Pensions Appeal Tribunals established by the War Pensions Act of 1919. The twelve tribunals now sitting dealt with over six hundred appeals per week. Additional tribunals were being set up.

Light Metal Limbs.—Major Cohen, on April 21st, asked the Minister of Pensions the price of the Government's new light metal limb, both as supplied by Messrs. Vickers and also when completely fitted with buckets, etc. Mr. Macpherson said it would not be expedient at this stage to publish details of the contracts placed with the limb makers in connexion with the light metal limb. He could state, however, that for the first issue of five hundred the total cost per limb would not exceed £30; the limbs were provided free to the pensioners.

Pneumonia Attributable to Naval Service.—Sir T. Bramsdon asked, on April 20th, whether, in view of the stringent medical examination applied to new entries to the Navy in peace time, which should make attributability more pronounced in the case of death or invaliding, some form of independent appeal board would be substituted to deal with any post-war cases in dispute, inasmuch as pneumonia, for instance, might be clearly due to the naval service, but there was no machinery for recording the circumstances attending each case, nor for bringing them to the notice of the medical officers who had to decide this important matter. Mr. Amery replied that it was not considered that such a board was necessary. From the time that a man entered the Navy until he left it a careful record was kept of his medical history, and before he was invalided for injury or disease all the details were fully known to the Board of Survey, who definitely gave their opinion as to attributability. Such a disease as pneumonia might well, in exceptional circumstances, be definitely given as attributable to service.

Anatomical Studies.—Sir H. Brittain asked, on April 20th, whether the Minister was aware that there was the greatest difficulty with regard to the proper prosecution of anatomical study in this country, and that a large number of British medical students were forced to prosecute or complete their studies in foreign hospitals or universities; whether this difficulty was mainly due to the inadequate supply of dead bodies for anatomical studies; and whether he would appoint a Select Committee to inquire into the matter. Sir A. Mond replied that, although it was the case that students had occasionally gone abroad to seek facilities to study anatomy, the difficulty at home had been remedied now by action taken by his predecessor; there was still a shortage in the case of certain provincial schools, but this was being remedied.

A Caravan Settlement.—Mr. Stuart asked, on April 13th, as to the reply of the Minister of Health to the petition of the Moreton District Council upon the subject of the caravan settlement in that and adjoining parishes; whether an expert in the Ministry of Health has reported upon the settlement; whether it contains about 1,100 caravans, many of which had merely bogus wheels and pretended to be movable residences, whereas they were not so; whether many tents were added

during the summer months, increasing the population by many thousands; and whether the conditions (as alleged in detail by Mr. Stuart) were such as to create a great danger. Sir A. Mond said he had received the report from a medical officer of the Ministry of Health, which was substantially in accordance with the statements of fact in the question. He was advised that the local authority had already sufficient powers to deal with the serious factors in the situation and he was in touch with them. Mr. Stuart inquired whether there was any way of limiting this evil in view of its alarming increase every year. The Minister repeated that the local authorities had full powers to deal with the matter. Mr. Stuart put it that an epidemic of typhoid fever was almost certain to arise, but Sir A. Mond said that it was the business of local authorities to see that these did not occur. Mr. Stuart said he was informed that the occupiers of caravans came to these places only in summer, and that the local authorities said they had no power to deal with them. Sir A. Mond rejoined that his advisers held to the contrary, but that if he found that the powers were inadequate he would go into the matter.

Harrow Medical Officer's Salary.—Mr. Mosley asked, on April 20th, whether the Minister of Health had requested the Harrow Urban District Council to raise the salary of their medical officer from the agreed sum of £180 per annum plus £20 allowances, to the sum of £230 per annum, plus £20 allowances. Sir A. Mond said that the approval of the Minister of Health had been asked for the appointment of a new medical officer of health at Harrow at the pre-war salary of £180 per annum plus allowances. The Urban District Council were informed that the salary was too low. The appointment and rate of salary were, however, sanctioned, as the council themselves contemplated three months. On the application of to £230, plus £20 allowances, was

THE BUDGET.

SELDOM during the past few years has a Budget been so effectively shorn of interest by anticipation or previous official announcement. Mr. Chamberlain publicly stated in Birmingham last February that the excess profits duty would be terminated and that no considerable change would be proposed in the income tax; and, as few would be sufficiently optimistic to expect any reduction in such duties as those on tea, tobacco, or spirits, in present circumstances, the main features of the new Budget have since then been regarded in the light of foregone conclusions.

The only surprise in his speech was that relating to the issue of a new loan to induce holders of bonds, the redemption of which is impending in the near future, to convert them into long-dated securities instead of claiming the redemption of their bonds, and thereby driving the Government to the money market for temporary loans, which would add to the already too heavy floating loans, aggravate the serious difficulty of the money market, and delay the hoped-for return to a lower bank rate and healthier conditions of industrial credit. The terms of the conversion loan seem to be sufficiently generous to ensure the attainment of its object.

Most of the fiscal controversies of the past few years have centred round the excess profits duty. The professional man, as such, is not directly concerned with that tax, but there is something to be said from his standpoint, for it is clearer than it ever was that a burden taken from the shoulder of one taxpayer implies either an additional burden on another taxpayer, or, as in the present instance, the retention of his burden without the relief that otherwise might have been afforded. A system of taxation should, if possible, comply with two main conditions: it should be fair as between one citizen and another, and it should inflict the minimum of harm on the citizens as a whole. The excess profits duty—or some modified form of it—is justifiable on grounds of equity in many cases, where an income greatly in excess of the pre-war income is still being enjoyed, but most if not all of the authorities seem to be agreed that its effect on the nation's industrial and commercial well-being is so harmful that it must go. Unfortunately, in this imperfect world, the two conditions are impossible of simultaneous fulfilment, and the man who is now enjoying an income which the war has helped him to double or more, is now freed from the special burden of the excess profits duty, not merely, or mainly, because that burden is unfair, but because the unfettered investment of his surplus income is desirable for the building up of industrial enterprises.

In this connexion the remarks of the Chancellor with regard to the operation of the three years' average are of interest. During the war provisions were very properly

inserted in the Acts to give relief to those taxpayers whose incomes had fallen owing to the war. That relief operated by suspending the three years' average, and it now appears that there is some doubt as to whether the law officers of the Crown are right in holding that that relief was abolished for 1920-21 and future years. The point is important, because if the relief does still operate the result would be that concerns which made large profits during the war would now escape their fair payment of income tax by substituting for the three years' average the profits of the comparatively unprofitable year 1920. For these reasons the course proposed—namely, to deal with the question by Act of Parliament instead of leaving it to the protracted and uncertain arbitrament of the courts, appears right and proper.

The Budget has taken precedence of the second reading of the Revenue Bill, the intention of which is to effect certain changes in administration and in the average basis of assessment as for the financial year 1922-23 and future years. There has been considerable discussion in the daily press as to the wisdom or unwisdom of the administrative changes proposed. On the one hand the proposals are supported as merely giving legal sanction to the existing practice in accordance with which the greater part of the assessing work is performed in most places by the inspector of taxes, on the other hand the proposals are attacked as giving that official an authority and opportunity for harassing the taxpayer which he should not be allowed to obtain. A reference to the report of the Royal Commission on Income Tax shows that the Revenue Bill is in the main intended to embody the unanimous views of the members of that Commission, and it is perhaps wise to suspend judgement until the bill has been discussed in Parliament.

After all, the dominating factor in the situation is that the standard rate of income tax remains at 6s. in the £, and a close scrutiny of the Budget figures suggests little hope of its early reduction. At the moment the demand for economy is loud and insistent, and it is well that it should be so; but there is a constant parliamentary pressure for schemes of social betterment which goes far to nullify efforts to secure a smaller national expenditure. On the revenue side, Mr. Chamberlain deliberately omitted from his anticipations any receipts from the German Indemnity, which is earmarked against repayment of national debt; but taking into account, on the other hand, the fact that before long some arrangement must be arrived at with the United States as to the accrued but postponed interest on our debt to that Government, it requires more optimism than we can summon to our aid to anticipate much relief in taxation through Germany meeting her obligations to this country, and thereby reducing the interest payable on our own National Debt.

To the professional man the Budget appears to be without any very distinctive features, and leaves him very much as it found him, thankful that it is no worse, but with little hope for any early relief from a burden of taxation which can be borne only by great personal sacrifice.

THE Committee of Livingstone College recently accepted with much regret the resignation of Dr. Loftus E. Wigram of his post as principal of the college, and appointed as his successor Dr. Tom Jays, who has served since October, 1919, as vice-principal.

THE report of the Carnegie United Kingdom Trust for 1920 contains an account of the many-sided activities of this body, which range from the publishing of music to the provision of play centres for children. In connexion with the valuable work which is being continued in regard to the provision of public libraries, £500 was given to the College of Nursing for the formation of a nurses' library in their new headquarters in Cavendish Square. A grant of £40,000 is to cover the lease, equipment, and sinking fund charges of No. 117, Piccadilly, which is the house of the London Central Institute for Infant and Child Welfare and its constituent child welfare societies. Of the six model infant and child welfare centres for which grants had been promised, the Motherwell centre, the report states, was the only one actually in course of erection. Among the miscellaneous grants was one of £1,000 a year for five years to the National Institute of Industrial Psychology, which is complementary to the official body, the Industrial Fatigue Research Board, and is under the direction of Dr. C. S. Myers, F.R.S.

England and Wales.

DINNER TO MR. R. A. BICKERSTETH, LIVERPOOL.

A LARGE number of his professional colleagues and friends assembled on April 20th to do honour to Mr. Robert A. Bickersteth, M.A., M.B., F.R.C.S., on the occasion of his resignation from the position of senior surgeon to the Liverpool Royal Infirmary. The success of the dinner was due to the efforts of Mr. Frank Jeans. Mr. H. Wade Deacon, chairman of the committee of the Royal Infirmary, presided, and after the loyal toasts had been honoured, Dr. Richard Caton, senior consulting physician, proposed the health of the guest. Dr. Caton said that the name of Bickersteth was a household one in the annals of the Royal Infirmary, and he hoped that in the future the name would again appear among those of the surgeons of the infirmary. He trusted that their guest would enjoy many years of happiness in his retirement to the north of England. Mr. Frank T. Paul, consulting surgeon, mentioned especially Mr. Bickersteth's work in urinary surgery, and that, as a major during the great war, Mr. Bickersteth devoted his attention to the wounded at Fazakerley Hospital, relinquishing his private practice in order to do so. Mr. F. Jeans, assistant surgeon to the Royal Infirmary, who worked with Mr. Bickersteth, gave a delightful account of the harmonious relationship of his staff. Mr. Keith Monsarrat (Liverpool Northern Hospital), Mr. G. P. Newbolt and Mr. Douglas Crawford (Royal Southern Hospital) testified to the character and skill of their colleague, and congratulated him on his retirement at an age when he could look forward to many years of healthful activity. The chairman of the infirmary emphasized especially the great value of the tact and judgement that Mr. Bickersteth was able to render in the management of hospital affairs. Mr. Bickersteth, in reply, said that he was gratified beyond expression to know that in leaving Liverpool he had left behind him a secure place in the esteem of his professional brethren.

THE LATE DR. ARNOLD JOHNSTON OF LEICESTER.

Many professional and social friends of the late Dr. Thomas Arnold Johnston, assistant physician and pathologist to the Leicester Royal Infirmary, were present on April 21st at the unveiling of a memorial tablet commemorating his work at the infirmary. Mr. N. C. Ridley, M.B., F.R.C.S. (ophthalmic surgeon), senior member of the honorary medical and surgical staff of the institution, who performed the ceremony, said that the tablet commemorated the sacrifice of a life freely given in the sacred cause of humanity, offered at the call of duty, in fighting a subtle and insidious foe in the laboratory, so that knowledge might be gained to enable the human race more effectively to withstand the attacks of disease. "Arnold Johnston," Mr. Ridley continued, "was a quiet modest man, albeit of a cheery and lovable disposition, who never spared himself when there was work to be done. He knew quite well the risks he was running, but although on two previous occasions he had been laid up with the same infection, he returned to his work and unfortunately contracted the disease a third time; he eventually succumbed after two years of great suffering, mitigated indeed by the faithful care and attention of a devoted wife and loving mother. As the senior member of the staff and also because possibly I knew him best, I have been asked to unveil this tablet to his memory, to show to future generations that the Leicester Royal Infirmary appreciates her sons and laments a young and promising life cut untimely short. As Horace most aptly expresses it:—

Quis desiderio sit pudor aut modus
Tam cari capitis!"

The inscription on the tablet is as follows: "To the memory of Thomas Arnold Johnston, M.D., Honorary Assistant Physician and First Pathologist to this Infirmary. Obiit 4th February, 1918."

VITAL STATISTICS.

The Registrar-General announces that the provisional figures of births registered during the first quarter of 1921 show a decline of over 61,000 when compared with those of the corresponding period of 1920. Compared with the

first quarter of 1914, however, the drop in numbers is under 8,000. Excluding the war years the births are the fewest recorded in the first quarter of any year since 1872. The provisional rate per 1,000 living is, with the exception of the war years 1916-19, the lowest ever recorded for any first quarter. The deaths registered also show a decline in numbers from the very low record of 1920, and are the smallest in number registered in the first quarter of any year since 1868. The provisional rate is the lowest ever recorded for any first quarter. The natural increase by excess of births over deaths was over 80,000, as compared with 133,000 in the March quarter of 1920 and 73,000 in 1914. The infant mortality was 101 per 1,000 births.

Ireland.

THE NEW ULSTER PARLIAMENT.

Selection of Unionist Candidates for Queen's University of Belfast.

At a meeting of the Queen's University Unionist Voters' Association, held on April 20th, in the Minor Hall, Y.M.C.A., Belfast, the following four candidates were selected: John Campbell, M.A., M.D., F.R.C.S.Eng., LL.D.(Hon.); R. J. Johnstone, B.A., M.B., F.R.C.S.Eng., Professor of Gynaecology in the Queen's University; H. S. Morrison, M.D., L.R.C.S.I., H.M. Coroner Coleraine District; and John H. Robb, B.A., B.L., a member of the North-East Circuit, author of some legal works, and well known in the North of Ireland.

Mr. Campbell is senior surgeon to the Samaritan Hospital for Diseases of Women, Belfast, and is well known as a consulting and operating gynaecologist; he was chairman of the old Royal University Graduates' Association, and is Chairman of Convocation of the Queen's University; he served in France for a time as chief surgeon of No. 5 British Red Cross Hospital, and was adjutant and second in command of the Queen's University Veterans Volunteer Corps. Professor R. J. Johnstone is gynaecologist to the Royal Victoria Hospital, Belfast; he has been for twelve years a member of the Council of the British Medical Association, and was actively engaged in the negotiations between the Government and the profession in connexion with the Insurance Act; he has been chairman of the Irish Medical Committee for the past six years; he is a member of the Council of the British Hospitals Association and was chairman for two years of the Hospitals Committee of the British Medical Association, and is one of the three medical members of the Nursing Council for Ireland. He served during the war as one of the surgeons of the U.V.F. Hospital. Dr. H. S. Morrison was put forward by the Medical Association of the County of Londonderry, and his nomination was heartily approved of by the Queen's University Unionist Voters' Association. For thirty years he has been an active supporter of the Ulster Unionist policy, and he is chairman of the South Londonderry Unionist Association, and of the County Londonderry Branch of the Irish Union Alliance; he is secretary of the Irish Medical Association of County Derry and has held many posts of public utility; he has retired from medical practice but still holds the coronership. Mr. Robb is a member of a medical family; his personal qualifications entitled him to the selection of the association; his claims were strengthened by his family record; his father (the Rev. J. Gardner Robb, D.D., LL.D.) was one of the early scholars of the old Queen's University, and his three brothers and himself have all passed through the portals of its successors: Dr. Gardner Robb, Medical Superintendent, Purdy's Barrn Fever Hospital; Lieut.-Colonel J. J. Robb, I.M.S.; and Captain Campbell Robb, R.A.M.C., P.M.O., Egyptian State Railways. All were well-known athletes in their day.

POOR LAW MEDICAL OFFICERS AND LOCAL GOVERNMENT RETURNS.

The "department of local government, Dáil Éireann" over twelve months ago ordered Irish Poor Law medical officers to discontinue sending, amongst other returns, Form L to the Local Government Board (Ireland). Dr. L. Rowan, Kildare, one of the medical officers, who has carried out the instructions of the Dáil Éireann local

government has written to the board of guardians, stating:

"I should be glad if you will communicate to the Board the fact that on the 10th inst. I received a communication from the Local Government Board (Ireland) in which they repeated the statement that the directions of your Board (re the September report) was illegal and invalid. They also express the opinion that resignation by me of my position as medical officer would have been in the circumstances 'the honourable way out.' They added that they had now decided to take a less drastic course than dismissal, and had directed their solicitor to apply in the High Court of Justice for a writ of mandamus to compel me to send in my report, all costs to be payable by me. I shall be glad to learn of and to follow any suggestion or procedure your Board may desire to adopt at this stage."

The board of guardians (Naas, co. Kildare) made an order that they would stand by Dr. Rowan and would indemnify him against any loss he may sustain arising out of any action taken by the "English" Local Government Board.

In connexion with this matter deputations from the Irish Medical Association and Irish Committee of the British Medical Association waited on the Vice Chairman and Medical Commissioners of the Local Government Board to point out the difficulties in which medical officers in many unions were placed by receiving contradictory orders from the Local Government Board and their boards of guardians. In some instances they were placed in actual danger if they continued to obey the regulations of the Local Government Board. It appeared to the deputation that it was unreasonable to expect medical officers to jeopardize their salaries, or possibly their personal safety, by obeying the regulations of the Local Government Board in cases in which the Government no longer contributed to their salaries. The deputation failed to see why medical officers had been singled out of the whole class of officials with threats of dismissal for failure to obey the orders of the Board. The deputations also drew the attention of the Local Government Board to the fact that in several unions medical officers had received no salaries for over twelve months. Members of the deputation expressed the opinion that there was very little hope of such doctors being paid their salaries until legislation was introduced amending the Criminal Injuries (Ireland) Act, 1920, which provided for the attachment of Poor Law medical officers' salaries to meet the awards made for malicious injuries, including those committed by the Crown Forces. It was also pointed out that the Government had made no effort to provide medical treatment for the necessitous poor whose plight would be infinitely worse had not the Irish medical profession tried to place its services gratuitously at their disposal.

At a meeting of the County Limerick Medical Committee, held on April 16th, the following resolution was unanimously adopted:

That the order, regarding Form L, of our Board of Guardians be complied with, and that in future it be sent to them alone. That the Honorary Secretary is directed to send copies of this resolution to secretaries of County Borough and Local Medical Committees.

NATIONAL UNIVERSITY OF IRELAND.

At a special meeting of the Senate of the National University of Ireland, held on April 19th, with Dr. Denis J. Coffey, Pro Vice Chancellor, in the chair, Dr. Michael F. Cox proposed a motion recording the loss sustained by the university in the death of the Most Rev. William J. Walsh, D.D., Archbishop of Dublin, the first Chancellor of the University. The resolution, which was unanimously adopted, recorded that it was in the main to the efforts of Dr. Walsh that the university owed its foundation, and that its success in surmounting the difficulties of its early years was largely due to his wise guidance.

Scotland.

GLASGOW POST GRADUATE MEDICAL ASSOCIATION.

A COMPREHENSIVE course of instruction for medical practitioners, extending from May to October, 1921, has been arranged under the auspices of this association. The hospitals taking part in the scheme include the Glasgow Royal Infirmary, the Western Infirmary, the Royal Hospital for Sick Children, the Royal Maternity Hospital and most of the other hospitals in Glasgow, the Glasgow Royal

Asylum, and the consumption sanatoriums for Scotland, Bridge of Weir. The classes have been arranged so that a practitioner may, if he so desires, occupy the greater part of each day in attending the classes and demonstrations of the course. In order to meet the needs of young graduates and others who may wish to obtain a closer acquaintance with hospital work in one or other of its branches, arrangements have been made by which a limited number may become attached to wards or outpatient departments as clinical assistants for definite periods, working under the direct supervision of the physician or surgeon in charge, and carrying out such detailed investigations as directed. A young graduate who wishes to obtain special knowledge of children's diseases, mental diseases, tuberculosis, venereal diseases, or other subjects, would find such training valuable. The post-graduate courses are conducted quite independently of the undergraduate courses, and a practitioner may enrol for one or other of several classes, and may attend for one or more months as he desires. Any further information may be obtained on application to Dr. A. M. Kennedy, secretary, Post Graduate Medical Association, The University, Glasgow.

ADVISORY COMMITTEE ON THE WELFARE OF THE BLIND.

The Scottish Board of Health has appointed a committee to advise it on matters connected with the care and supervision of the blind, including any question which may be specially referred to the committee by the Board. There are fifteen members of this advisory committee, and it is rather surprising to find that only one of them is a medical man—Dr. George Mackay, P.R.C.S. Edin., than whom, of course, no better single selection could have been made. The secretary to the committee, to whom all communications should be forwarded, is Mr. W. R. H. Johnston, Scottish Board of Health, 125, George Street, Edinburgh.

Correspondence.

THE SITE OF OPERATION FOR EMPYEMA.

SIR,—May I venture to raise the question of the point of election in operation for empyema?

At a V.A.D. hospital during the war I was very much struck with the number of cases of lingering empyema. They were practically all alike in one respect, showing scars of successive operations of which the earliest was at the back.

Lately there has come under my care another case in which intermittent discharge is still taking place from the last operation wound. It is like all the others, presenting three scars, the first well to the back, the second about the mid-axillary line, and the last—where I think the first should have been—between the mid axillary and nipple lines.

I am convinced that if the first operation had been performed at the last named point this man would have been spared weeks of protracted suppuration together with two further operations.

In my student days in the eighties we were taught that the compressed lung lay at the back, and that in expanding after operation it gradually covered the inner surface of the ribs from behind forwards, the last portion to come in contact with the chest wall being towards the front. A posterior opening was therefore covered by the advancing lung while pus still remained in front, and drainage was thus interfered with, or if the opening were made too low the rising diaphragm might cover and obstruct it. Of course there are many cases in which the presence of adhesions may localize the collection of pus in any direction, but this was the teaching in respect of ordinary uncomplicated empyema, especially in children.

It is well summarized in Erichsen's *Surgery*, eighth edition, vol. ii, p. 701, where John Marshall is fully quoted in support of the anterior opening, the conclusion being:

"The space between the fifth and sixth ribs, an inch to an inch and a half in front of the mid axillary line, will probably be the best in most cases."

I remember well the almost uniformly successful results of operation at this point both at St Thomas's and at the Victoria Hospital for Children, Chelsea.

I was surprised to see these cases of posterior opening, until, in a modern *System of Surgery*—Burghard's, 1914—I found the posterior opening strongly supported (vol. iii, p. 711) by Sir Rickman Godlee, who says:

"I have no hesitation in recommending a posterior opening both on theoretical grounds and as a result of experience, the best place being, in my opinion, the region of the ninth or tenth rib, not far from the scapular line," and goes so far as to add: "I have often had to make a posterior incision when a lateral one has failed to effect a cure, but never to make a lateral one when a posterior one has proved inefficient." (The italics are mine.)

An old teacher of mine used to say that the opening of an empyema behind the mid-axillary line should be made a criminal offence.

Which of these teachings should we follow? It is a point which experience should have decided, and I shall be glad to learn what the decision is.—I am, etc.,

Bromsgrove, April 22nd.

H. CAMERON KIDD.

THE SCIENCE OF ETIOLOGY, OR THE NEW EPIDEMIOLOGY.

SIR,—It is very good-natured of your correspondent to remind me that the "problem of causation" is of interest to clinicians and bacteriologists; a little point like that might so easily be overlooked. One good turn deserves another, so I will "venture to remind" him that zeal on behalf of the problem of causation is an insufficient excuse for roundly asserting that epidemiologists, whether new or old, renounce the laborious accumulation of facts, and for hinting that some other persons have a monopoly of "persistent endeavour," of "well-controlled and repeated observation," in short, of all the qualities which go to make up genuine scientific work in any field.

In normal times these exaggerations are merely amusing; in times like ours, when all men seem to wish to believe that $2+2$ is any number you like except 4, they are mischievous. To become a genuine bacteriologist is as hard as to acquire any other intellectual discipline; the mere patter of the subject is easily picked up. But the dullest man in the street perceives that to become familiar with the A B C of general epidemiology (quite apart from any special mathematical or statistical technique) is a laborious undertaking not to be completed in a few days. Nearly a hundred years ago Macaulay said that there were many persons "who, having read little, or nothing, are delighted to be rescued from the sense of their own inferiority by some teacher who assures them that the studies which they have neglected are of no value, puts five or six phrases into their mouths, lends them an old number of the *Westminster Review*, and in a month transforms them into philosophers."

Many of these people now seek to instruct the public in preventive medicine. What they want to be able to say is that the whole problem of disease as a mass phenomenon is reducible to the chasing of a "germ" and the discovery of a "vaccine," that the laborious accumulation—with apologies to your correspondent—of epidemiological facts and the statistical analysis of such facts are waste of energy. Of course these things will be said whatever we may do; nothing short of an earthquake will prevent the "medical correspondent" of at least one daily paper from announcing to the world that some old wife's tale or piece of laboratory tea-table gossip is the latest discovery of science. But for our own credit's sake we should give this "home chat" science no quarter in professional circles. It is simply not true that any particular school of medical investigators has a monopoly of wisdom or patent rights in the discovery of truth.

If bacteriologists have a fault—mind, I say if—it is that they have been a shade too complacent in accepting the homage of the man in the street or newspaper office on the look-out for a new Witch Doctor.—I am, etc.,

Loughton, April 23rd.

MAJOR GREENWOOD.

THE VALUE OF THE WASSERMANN REACTION.

SIR,—Three months ago a patient came under my care with a history of having contracted syphilis in March, 1920. He had no treatment until May, when he developed

a rash and a sore throat. The Wassermann reaction was then "strong positive." During the next eight months he was treated with seven injections of novarsenobenzol, combined with mercury in pill form.

In November last, he stated, the Wassermann reaction was still "strong positive." When I saw him there were no clinical signs of syphilis, but the blood serum when tested for the third time gave the same result.

Since January I have given him over four grams of novarsenobenzol with continuous mercurial treatment, and as I considered that this was a case in which the return of either a positive or a negative reaction was possible I decided to obtain the opinion of two pathologists independently. Even if they did not agree absolutely I hoped at least that they would not markedly differ. When, however, the first (1) report was "negative" and the second (2) was "doubtful strong positive," results not only dissimilar but even aggressively antagonistic, I sent further samples of the serum to three other pathologists. These reported (3) "negative," (4) "strong positive," and (5) "doubtful negative." Incidentally, I may state, I obtained a negative result by the new formalin reaction of Gaté and Papacostas. The five pathologists to whom I sent serum are all well-recognized and experienced authorities on the subject.

While one fully recognizes the value of the test, its advantages and its limitations, returns of the above kind with such divergent opinions are somewhat startling; and one wonders how often an unjust verdict is given upon an individual, and treatment or the lack of it advised, when his fate is settled solely by the report from the laboratory.

In view of these results it would be interesting to hear the views of other workers on this subject, whether clinicians or pathologists.—I am, etc.,

London, W.1., April 25th.

KENNETH DICKSON.

ETHANESAL ANAESTHESIA.

SIR,—I have used this new anaesthetic, "ethanesal," in several cases since attending the meeting of the Royal Society of Medicine at which its claims to recognition were publicly advanced, and I am bound to say that so far my limited experience in its use leads me to speak favourably of it. I have not, except in the case of children, used it by the "open method." I induce with ethyl chloride, or with nitrous oxide gas (the patient having received a preliminary injection of atropine sulphate gr. 1/100), followed by ethanesal in a wide-bore Clover inhaler, and when induction is complete I pass on to ethanesal given by a "Shipway" outfit and warmed. I have found that by this method rather more anaesthetic is used than was formerly used of ether, but there are distinct advantages in respect of its after-effects to the patient.

I have on two occasions had to repeat the anaesthetization of patients who had been anaesthetized by me with similar methods by ether.

In one case the patient, a very obese lady, was anaesthetized by me for the removal of breast tumour. I used the same methods as stated above, except that ether was the anaesthetic used; she was very sick after the operation and also on the day following, and was nauseated by the taste of stale ether for several days. She was anaesthetized by me three weeks later for the complete removal of the breast, and this time ethanesal was used in place of ether. The second operation lasted more than twice as long as the first, but she was hardly sick at all afterwards; there was no prolonged nausea, and she was able to eat her breakfast next morning. When questioned as to the merits of the two anaesthetics, she was emphatic in her opinion as to the preferability of the new anaesthetic.

In the other case the patient was a boy, who was being operated upon for hypospadias. The boy was very sick after "open ether" administered by me with ordinary ether. On the second occasion I gave him ethanesal, also by the open method, and this time he was hardly sick at all, merely bringing up a little swallowed mucus.

I have given the new anaesthetic in two difficult abdominal cases, one a case of obstruction of the intestines by a band, the other a hysterectomy for fibroids complicated by multiple ovarian cysts in a patient of 62; in each case perfect relaxation was obtained, and in neither case was there any post-anaesthetic vomiting. I have administered the new mixture in two cases of piles, and in each the anaesthesia was satisfactory and resulted in good relaxation.

I think that ethauesal acts more thoroughly when administered warm, and for that reason, in the case of adults, and especially when the operation is likely to be prolonged, I use some form of "Shipway" apparatus. I have found that ethauesal is very apt to freeze on the guazo mask when administered by "open" or "perilational" methods, and this probably accounts for Dr. Charnock Smith's inability to get good relaxation in the case he cites in your issue of April 23rd. My limited experience, in fine, does not bear out his contentious therein expressed, except in so far as the cost of the "ethauesal" is concerned, but this is of small moment where the after-comfort of the patient is concerned.—I am, etc.,

H. PINTO-LEITE,

Hon Assistant Administrator of Anaesthetics,
London, W., April 23rd. the Westminster Hospital, etc.

SIR,—Dr. Charnock Smith, in your issue of April 23rd, says that he has had difficulty with ethauesal as an anaesthetic, but as he only cites one case, and that one induced on a CE mixture, I venture to suggest that the conclusions he draws are not quite justified. This anaesthetic requires practice just as any other, and is quite different from ether in its effects. For instance, Dr. Smith mentions using 1 oz. in five minutes. I have never used anything approaching this quantity, and nearly always find that considerably less is required than with ether. This is because the liquid is more analgesic than ether, and patients can be kept lightly under. Dr. Smith also says that ethauesal anaesthesia is too light for abdominal or rectal work. It has been given in this hospital for practically every well-known abdominal and rectal operation, including hysterectomy, cholecystectomy, colectomy, gastro-enterostomy, gastrectomy, and ileo-sigmoidostomy, and no difficulty has been experienced in obtaining absolute relaxation. I personally have known of about 500 cases which have been anaesthetized with ethauesal by myself and other anaesthetists, and have not heard of one which could not be kept under with this anaesthetic only.—I am, etc.,

C. LANGTON HEWER, M.B., B.S.

St. Bartholomew's Hospital, London, E.C.
April 22nd.

SIR,—After reading Dr. C. Charnock Smith's experience in the use of ethauesal in one case, I should like to give mine in twenty-one cases. The operations have been for tonsils and adenoids, mammary and other abscesses, varicose veins, multiple extractions of teeth, fistula in ano, etc.; in the last case a little chloroform, just before the operation started, was given with the ethauesal, 1 in 32.

In all the cases I have found ethauesal less irritating than ordinary ether; there was very little mucus and salivation, and the after effects were practically nil—no headache, vomiting, nausea, smell or taste of the anaesthetic. Patients who have had both ether and ethauesal say they do not mind the latter, but they do not want ether any more.—I am, etc.,

ALBERT B. COCKER, M.R.C.S., L.R.C.P.

Palmer's Green, N.,
April 23rd.

SIR,—It is interesting, when so many investigators are engaged in working in the straight but very long road of science, that, as a report of the recent meeting of the Royal Society of Medicine shows, someone has had time and opportunity to go on a mission of discovery in the side lane of anaesthesia. The report suggests that this was not a blind alley, and that ethauesal has to a certain extent passed through the fire of use, and come out, if not pure gold, anyway a glowing piece of colour in the "anaesthetic rag bag." As an uninterested anaesthetist, I wish to bear testimony to its value. Induction, which I obtained by the use of my percentage inhaler, was rapid when an extra strength was obtained by dropping the anaesthetic on gauze over the air pipe, and anaesthesia was easily maintained by bubbling oxygen at first through, but mostly over, jacketed ethauesal.—I am, etc.,

CHARLES T. W. HIRSCH,
Anaesthetist, Samaritan, London
Temperance Hospitals.

London, S.W., April 21st.

PRURITUS ANI.

SIR,—I am in agreement with much that was said at the discussion on April 13th on pruritus ani by the Subsection of Proctology of the Royal Society of Medicine (reported in the JOURNAL of April 23rd), more especially with the statement that in the local treatment attention to cleanliness and dryness and avoiding the use of ointments and greasy preparations is of the first importance.

A point, however, which seems to have been overlooked by all who spoke on treatment is the important one of shaving away all hairs found growing around the anus and between the opposing surfaces of the hips. In some cases no hairs are found in that region, but in many where the disease exists I have found that the hairs, by occasioning irritation of the skin, were the *primo* cause of the itching. I instruct the patient to wash the parts with warm water and soap after defaecation; then to use a safety razor in removing all hairs, finally to douche the parts with either boric lotion or plain water or both, hot or cold, and dry carefully with a soft towel. This washing is to be carried out after every movement of the bowel, and again before retiring to rest. The shaving will require to be repeated about every ten days, and does not occasion any inconvenience. By attention to these details cures may be quickly effected in cases that have given trouble for years and after the failure of varied treatment.—I am, etc.,

Londonderry, April 25th.

D. A. MCCURDY, F.R.C.S.I.

IRRITABLE BLADDER.

SIR,—There is little doubt that in certain cases the chemical and physical properties of the urine play an important part in the causation of increased frequency of micturition. One of your recent correspondents refers to alkalinity of the urine, and I would point out that unless the indicator used be stated, or some other means of denoting ionic concentration be employed, the terms acid and alkaline are very vague. During the past two years I have titrated a considerable number of specimens of urine from various sources, and using phenolphthalein as an indicator have only on one occasion found an alkaline reaction, even after the patients had been treated with bicarbonates and citrates of sodium, although such treatment may rapidly reduce the acidity as shown by titration.

It is probable that the osmotic pressure of the urine is at least as important a factor in causation of frequency of micturition as the reaction to indicators, since the ingestion of large amounts of sodium chloride may produce irritability of the bladder. A method of treatment worthy of consideration is to impress upon patients the necessity of drinking larger amounts of water than they have previously been taking; this will frequently produce satisfactory results.

In certain cases the administration of methylene blue capsules in addition has a beneficial effect, not only on account of the medicinal properties of this drug, but also by reason of the psychological influence of the coloured urine, which makes patients realize that something is being done for them.—I am, etc.,

Bristol, April 19th.

OLIVER C. M. DAVIS.

Universities and Colleges.

UNIVERSITY OF MANCHESTER.

THE following appointments have been made: *Reader in Electro-chemistry*, Mr. A. G. Lobley. *Lecturer in Practical Surgery*, Mr. E. D. Telford. *Clinical Lecturer in Mental Diseases*, Dr. John Sutcliffe. *Lecturer in Mental Diseases*, Dr. David Orr.

A large number of French books presented by the French Government have been placed in the University library.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

At the first summer commencements in Trinity Term, held on April 19th, the following degrees in medicine, surgery, and midwifery were conferred:

M.B., B.Ch., B.A.O.—J. A. Acheson, D. J. Browne, T. F. L. Cary, B. S. Chapman, R. H. J. M. Corbett, P. J. Healy, L. Herzenberg, Mary Horan, D. V. Leatham, J. D. Leahy, P. I. Levitt, R. W. Power, E. C. Smith (B.Ch. sub cond.), J. A. Smith, Elmor D. Stoford. *In absentia*: D. de Bruyn, F. X. Pratt, R. H. Satchwell, J. B. Taylor (antea lic).
M.D.—H. Muller.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Honour for American Surgeons.

At a meeting of the President, Vice-President and Council, it was unanimously resolved to confer the Honorary Fellowship of the College upon the following distinguished American surgeons: W. J. Mayo, Mayo Clinic, Rochester, U.S.A.; C. H. Mayo, Mayo Clinic, Rochester, U.S.A.; Geo. E. Brewer, New York; Geo. W. Crile, Cleveland, Ohio; Richard H. Harte, Philadelphia; W. W. Keen, Philadelphia; John M. T. Finney, Baltimore; A. J. Ochsner, Chicago. It is hoped that the ceremony will take place in the early autumn.

Obituary.

ARTHUR F. DOBBS, M.B., T.C.D.,
Athlone.

DR. ARTHUR FRANCIS DOBBS died unexpectedly on April 20th. As usual with him, he was early at work in the Military Barracks, where he complained of not feeling well and was brought home. Late in the day he became unconscious, and before the evening sun had set he had gone to his reward.

He entered Trinity College, Dublin, in the early seventies, and had had a brilliant career in the arts school before entering the medical, from which he graduated M.B., Ch.B. in 1877. After practising for some years in the Federated Malay States he started in private practice in Athlone, where in a short time he acquired a large and widely-spread practice, becoming successively civil surgeon to the military, medical attendant on the police, the post office, the Great Southern and Western Railway and to the Incorporated Society's schools. His opinion was much sought after by his colleagues, who warmly appreciated the unerring rectitude of his ethical sense, his wide knowledge of professional matters and accuracy of diagnosis, coupled with an intimate knowledge of the newer developments.

Those who knew Arthur Dobbs and who were his friends will miss much more than a genial colleague. He was descended from a race which has helped to mould the history of the country in the Irish Parliament, and which had an hereditary appanage in the borough of Carrickfergus, of whom perhaps the most distinguished member was that Francis Dobbs who occupied no small place in the ranks of the county members during Grattan's Parliament, and who is frequently spoken of in the records of the period as "Millennium" Dobbs, from a pamphlet he wrote proving the immediate imminence of the millennium, which was one of the reasons he adduced against the Union in the closing stages of Grattan's Parliament. Lecky records of him that "He was a man of respectable family and private means, of an eminently pure, gentle, honourable, and benevolent character." The words apply with equal force to his descendant, except as to the private means. Arthur Dobbs was hospitable, kindly, courteous, and benevolent, placed his best services at the disposal of the poor and needy as readily as at those of his richest clients.

J. M.

Sir ARTHUR BALL, F.R.C.S.I., writes: The death of Dr. Arthur Dobbs, of Athlone, will be felt as a personal sorrow by many medical men in Ireland, and all classes, particularly the poor over a wide area in the Midlands, will truly mourn his loss. Dr. Dobbs was of the type of practitioner that is unfortunately dying out in this country—a man able to get on well with those of all classes, creeds and politics. Although working away from modern hospital facilities, he kept himself up to date by post-graduate classes and books in a wonderful manner. He was a man of considerable resources in emergencies—he had operated on a strangulated hernia successfully in a dirty cottage, with no assistance and by the light of a candle. Another instance: Called to see a poor woman far out in the country, he found her enormously distended, apparently dying from intestinal obstruction; it was impossible to get her moved to a hospital and no surgical aid was available. Instead of leaving her to die, Dobbs followed what I believe is a method sometimes carried out in cattle, and punctured the obstructed bowel through the abdominal wall in several places with a hypodermic needle and allowed the flatus to escape, with the result that the patient improved and he was able to get her moved to Dublin the following day, where the obstruction was successfully dealt with by operation. A life saved by taking a risk which most of us would have hesitated to

take. Military duties during the war and the tragic state of the country since prevented him taking any rest from his work. He had on several occasions during the past year intended taking a few days' rest, but something always turned up to prevent him. Want of rest, the strain of the present troubled times caused the end, but he died, as I am sure he would have wished, at the post of duty.

DR. DAVID VALENTINE REES died at his residence at Brecon, on April 13th, aged 67. He was educated at Llandovery College and the London Hospital, and took the diplomas of M.R.C.S. in 1875 and that of L.R.C.P. Lond. in 1876. After serving as house-surgeon and house-physician at the London Hospital and junior house-surgeon to the Poplar Hospital, he commenced practice forty years ago in Brecon, where he built up a wide and influential connexion. At the time of his death he was senior surgeon to the Brecknock Infirmary, M.O.H. to the Urban District Council, and a member of the War Pensions Medical Board. During the war he served at the Penoyre (Brecon) and Bulth Wells Red Cross Hospitals and did a great deal of work at the Brecon barracks in addition to serving on the local medical board. He was awarded the O.B.E. in 1919. For twenty-six years he held a combatant officer's commission in the local volunteers and their successors, the Territorials, and had attained the rank of major. He was a J.P. for the county and a member of the North Glamorgan and Brecknock Division of the British Medical Association. He is survived by his widow and one son.

DR. FREDERICK J. BURMAN of Wath-on-Dearne, whose death from injuries caused by a motor-car occurred on April 15th, was educated at Leeds. He took the diploma of M.R.C.S. in 1883, and L.R.C.P. Edin. and L.M. in 1886. He had resided in Wath-on-Dearne, and ultimately succeeded to the practice established by his grandfather and afterwards carried on by his father. He was medical officer of the Wath, Rotherham, etc., Joint Hospital, M.O.H. and medical officer and public vaccinator for Wath-on-Dearne, certifying factory surgeon, and a member of the Barnsley Division of the British Medical Association. He was also an examiner for the St. John Ambulance Association and a vice-president of the Yorkshire Branch of the Society of Medical Officers of Health. For the last two years Dr. Burman had held the position of vicar's warden at the Wath parish church. He leaves a widow and one daughter.

DR. SAMUEL WALKER, one of the oldest medical practitioners in Middlesbrough, died on April 17th, aged 77. He received his medical education at Guy's Hospital, and took the diplomas of M.R.C.S. Eng. and L.S.A. in 1870. After serving as house-surgeon at the West London Hospital and the Northampton Infirmary he commenced practice in Middlesbrough. He was a J.P. for Middlesbrough, and an ex-President of the North of England Branch of the British Medical Association. He had been a Freemason for forty years, and was the oldest past-master of the Ferrum Lodge, and in addition held high degrees in another lodge. His wife died about two years ago, but he leaves three daughters and two sons.

THE death is reported of Dr. ALFRED ERNEST W. RAMSBOTTOM, of Heilbron, Orange Free State, aged 60. He was born at Grahamstown, the son of Mr. William Ramsbottom. He received his medical education in Dublin, and took the diplomas of L.R.C.S.I. in 1882, L.R.C.P.I. and L.M. in 1883, and F.R.C.S.I. in 1896, and graduated M.D. Durh. in 1902. He practised at Fauresmith and Bloemfontein, and acted as chief medical officer of the Orange Free State forces during the Boer war. On the conclusion of peace he resumed his practice at Bloemfontein, but in recent years carried on his medical work at Heilbron. He was a member of the Orange Free State and Basutoland Branch of the British Medical Association, and held the portfolio of treasurer of the Orange River Colony from 1907 to 1910, when he was appointed the first administrator of the Orange Free State on the formation of the Union of South Africa. It was while on a visit to London with reference to post-graduate study that he was seized with illness which proved fatal.

Medical News.

THE course of lectures on pathological research in its relation to medicine commenced at the Institute of Pathology and Research, St. Mary's Hospital, Paddington, on April 28th, when Sir Almroth Wright dealt with acidosis and acidæmia, with special reference to gas gangrene, shock and scurvy. Professor Leonard Hill will lecture on May 5th, at 4.30 p.m., on capillary blood pressure and oedema. The lecture on May 12th will be given by Sir James Mackenzie, who will urge that the opportunities of the general practitioner are essential for the investigation of disease and for the progress of medicine.

THE next course of lectures by the Gresham Professor of Physic will be delivered by Sir Robert Armstrong-Jones, M.D., on May 2nd, May 3rd, May 4th, May 6th, at 6 o'clock, at Gresham College, Basinghall Street, E.C. The subject will be "Our Drinks: water, milk, wines, ales, and spirits." The lectures are free to the public.

THE number published on April 15th of the *Periodical*, a circular issued by the Oxford Press, announces that "the *Lancet* has come under the control of Henry Frowde and Hodder and Stoughton (Oxford Medical Publications), but there will be no change in the editor or the policy of the paper."

AT the meeting of the Röntgen Society in Manchester next Friday (May 6th), the afternoon session will begin in the Physics department of the University at 4.30, when a series of demonstrations will be given. There will be a dinner in the Refectory at 6.30, and the evening session, when the application of radiology to the examination of metals will be explained by Professor W. L. Bragg and the Director of Radiological Research, Royal Arsenal, Woolwich, will begin at 7.30. Saturday will be spent in visiting the x-ray and electrical departments of the Royal Infirmary and Radium Institute, and various works will be open to inspection. The meeting is open to non-members, who can obtain further particulars from the honorary secretary, Dr. R. W. A. Salmond, 51, Welbeck Street, London, W.1.

THE annual dinner of the Indian Medical Service will be held at the Trocadero on Wednesday, June 15th, Major-General Sir R. Harlock, Charles, G.C.V.O., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S.(ret.), 63, Addison Road, Kensington, W.14.

DR. WILLIAM HUNTER will give a course of three Chadwick public lectures on the prevention and control of fevers in England, with special reference to the effect of the Public Health Acts (1848-1918). This review of a century's progress will be illustrated by maps and epidiascope pictures and diagrams. The lectures will be given at the house of the Medical Society of London (11, Chandos Street, W.1) on Thursdays, May 5th, 12th, and 19th, at 5.15 p.m.

THE Executive Council of the National Association of Insurance Committees, at a meeting held on April 15th, adopted a resolution placing on record its appreciation of the great service rendered by the Right Hon. Christopher Addison, M.D., M.P., in the cause of public health, and its grateful recognition of the prominent part he took in the establishment of National Health Insurance and his work as first Minister of Health. They expressed the hope that the policy initiated by him at the Ministry of Health will be vigorously pursued.

AN agreement has been made between Sweden, Norway, and Denmark to draw up a common pharmacopoeia.

THE celebrated anatomist and anthropologist Professor Heinrich Wilhelm von Waldeyer has recently died in Berlin in his 85th year.

THE first number of the *American Journal of Tropical Medicine*, bearing date January, 1921, has now reached this country. It is described as the official organ of the American Society of Tropical Medicine, and this first number contains the address of the president, and a report of the secretary for 1919-20, together with a list of members. The first paper consists of medical notes on the Dominican Republic and Haiti, and another deals with the carriers of *Entamoeba dysenteriae* among soldiers returned from overseas. Among the conclusions of this paper are that the number of carriers in the United States has been greatly increased by infections in soldiers returning from overseas, and that a larger number of carriers than has hitherto been suspected exists in the normal population. The annual subscription to British subscribers is 25s., and the publishers are Williams and Williams Company, Baltimore, U.S.A.

AT a meeting of the Naval, Military and Air Force Hygiene Group of the Society of Medical Officers of Health, to be held, with the kind permission of the Commandant of the College, at the Royal Army Medical College, Grosvenor Road, S.W.1, on Friday, May 6th, at 4 p.m., Lieutenant-Colonel P. S. Lelcan, C.B., Professor of Hygiene, will give a demonstration of "Sanitary appliances of interest to all health officers." The demonstration is open to all members of the society.

WE are asked to state that there is no foundation for the rumour that the baths at Harrogate are closing down owing to the coal strike.

THE Scottish Board of Health has issued regulations extending the period in which chicken-pox is compulsorily notifiable until October 1st, 1921.

SIR ARTHUR N. WISHON, K.C.B., arrived at Liverpool on April 25th, after completion of his engagement at Johns Hopkins University.

THE second annual dinner and reunion of officers of No. 20 General Hospital, B.E.F., will be held at the Florence Restaurant, Rupert Street, W.1, on Saturday, May 14th, at 7 for 7.30. Those who wish to be present are asked to apply on or before May 2nd to the Honorary Secretary, Mr. Harold Drinkwater, 7, Cavendish Place, W.1.

MAJOR J. H. DOUGLASS, O.B.E., M.D., R.A.M.C., of Lincoln's Inn, and Dr. T. M. Davie, M.C., of the Inner Temple, have been called to the Bar.

A COURSE of ten lectures on elementary psychotherapy will be given by Dr. H. Crichton Miller at the Kingsway Hall, Kingsway, W.C.1, on Fridays, beginning May 6th, at 5.15 p.m. The fee for the course is £2 2s. for medical practitioners and £1 1s. for medical students. Tickets can be obtained from the honorary lecture secretary, 51, Tavistock Square, W.C.1.

REUTER'S agent, telegraphing from Alexandria on April 21st, stated that plague had broken out in Egypt, a daily average of 35 cases being reported. Vessels are detained in quarantine at Alexandria. Three hundred and forty two cases of plague occurred in Java during January, and 333 in February, all of which were fatal.

THE New York Institute of Radium has recently acquired 500 mg. of radium.

ABOUT a year ago we published a short note by Dr. D. W. Samways of Mentone about Brides les Bains, sometimes called the French Carlsbad, because the water very closely resembles the Sprudel source at Carlsbad, the total mineralization being about the same, the constituents very similar, and the quantity of free carbonic acid gas identical. Dr. Jean Leray, who practises at Brides, informs us that the establishment and baths have been greatly improved, as has also the hotel accommodation. The place is reached through Aix-les-Bains, the nearest station being Moutiers.

ON June 18th next will be celebrated the octocentenary of the founding of Reading Abbey by King Henry Beaucherc. In honour of the occasion Mr. Elliot Stock will publish an illustrated memorial volume by Dr. J. B. Hurry.

A SPECIAL meeting of the Fellows of the Royal Society of Medicine was held on April 25th to consider the recommendation of the Council that the subscription of all the Fellows in the London postal area should be raised to five guineas, and that of Fellows residing elsewhere in the United Kingdom to four guineas; to this recommendation an amendment was moved by Dr. H. H. Dale and seconded by Dr. W. Bulloch, to the effect that while the subscription for Fellows with an address within a mile of the Society's house should remain at five guineas as at present, and the subscription for Fellows residing elsewhere should be raised to four guineas, one guinea should be remitted from the subscription of any Fellow who did not desire to receive the *Proceedings*. In the discussion which ensued it became evident that the majority of those present were in favour of drastic reduction in the size and circulation of the *Proceedings*. It was pointed out that the proposal might have a serious effect on the original agreement for the amalgamation of the societies whereby the Royal Society of Medicine was formed. The amendment, however, was pressed on two grounds. First, that the vote would afford evidence of the general feeling regarding the *Proceedings*, and secondly, that it would avoid resignations, especially from the "laboratory" sections. When put to the meeting, 84 voted for the amendment and 53 against. As a two-thirds majority was requisite, the amendment is not operative as it stands, but the suggestion it contains will be considered by the Council of the Society, and the matter brought before a future meeting of Fellows.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ACTIONS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attitology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"HEALTH OFFICER ABROAD" inquires for any official pamphlet on lethargic encephalitis.

* * The Ministry of Health, as recorded in our issue of March 5th, p. 357, has issued a pamphlet (H.M. Stationery Office, through any bookseller, ld.) on the symptomatology, diagnosis, and treatment of lethargic encephalitis.

"PUZZLED" writes: Can anyone suggest a treatment for the most intolerable itching following supraorbital herpes. There is no pain, but the itching is so severe that the patient literally tears holes in her forehead and scalp. I have divided the supraorbital nerves, but with no benefit. The victim is a lady of 45, and the attack of herpes occurred in September, 1920.

X-RAY DERMATITIS.

"J. A. P." asks for advice in the treatment of a case of x-ray dermatitis on the back of the head and the front of the thighs. Only starch poultices give relief, but the trouble is slowly spreading; the patient is also suffering from nephritis.

INCOME TAX.

"A. G." inquires as to the allowance of expenses incurred in connexion with purchase and sale of cars. The transactions were as follows:

1913. 11.5 h.p. car (A) bought for £235.
1916. This having broken down and its immediate repair being impracticable another make (B) was bought for £135, and that amount was allowed by the tax inspector.
1920. The first car (A) was sold for £90, and a third car—11.9 h.p. (C)—bought for £345.

The inspector considers that for income tax purposes (C) is replacement of (B).

* * It seems to us that the net cost of using the (B) car was a special expense arising out of the break down of the (A) and was not a replacement. In that case "A. G." would be entitled to a further allowance as follows:

Gross cost in 1920 of a 11.9 h.p. (A) or equivalent—say	£500
Deduct	
(1) Amount obtained for (A)	£90
(2) Amount obtained for (B)	85
	175

Net amount to be allowed	£325
--------------------------	------

If (B) is to be regarded as a replacement of (A) and (C) as a replacement of (B) "A. G." is still entitled to a further allowance equivalent to the difference between the cost price of a 11.5 (C) in 1920 and £90 plus £135 (the original cost of (B)). The amount to be deducted from the expenses in respect of the private use of the car depends so much on the circumstances that no general rule, 10 per cent. or otherwise, seems applicable.

"X" gave up his practice and has since done work as a locum tenent. How does this affect his liability?

* * In our opinion the earnings as a general practitioner, assessable under Case I, Schedule D, cannot properly be averaged with prior or subsequent earnings as a locum tenent, such earnings being the result of "employment" and consequent assessable under Case II, Schedule D. This

contention is supported by the fact that the practitioner's earnings fall into the average of the purchaser of the practice. We suggest that "X" should claim, as he has a legal right to do, to have his case set down for hearing by the Income Tax Commissioners and that he write to the inspector of taxes accordingly.

"IGNOTUS" asks: Can a salaried assessor of the Ministry of Pensions who, by the terms of his contract, is not allowed to practise, claim a deduction for expenditure on medical books and subscriptions to medical societies, both being necessary for keeping up his medical knowledge?

* * Yes, provided that the expenditure is exclusively incurred for that purpose; no doubt other purposes are also served to some extent, but it would seem to be splitting hairs to urge that the claim should be refused on that ground.

"E. M. D." inquires whether a grant from the Medical Research Council is liable to tax.

* * We understand that a substantial portion of the grant has been necessarily expended in carrying out the research for which the grant was paid. We are of opinion that for tax purposes the surplus over and above such expenditure must be regarded as a fee paid for work done, and as such is assessable. Particulars of the deductions claimed for expenses should be given on the space provided on the Schedule E form of declaration.

LETTERS, NOTES, ETC.

MESSRS. PARKE, DAVIS AND CO. have issued a descriptive catalogue of the products of their laboratories, which also contains in an "index of therapeutics" many suggestions for treatment. From the same firm comes the tenth edition of the little book entitled *Vaccine Therapy*, which contains instructions for using the vaccines prepared in the laboratory of St. Mary's Hospital. Considerable alterations have been made in this edition, and the sections relating to acne, streptococcal infections, influenza, typhoid fever and whooping cough have been largely rewritten, while the composition of the following vaccines has been altered: acne and mixed acne, antisepsis (mixed staphylococcus and streptococcus), and whooping-cough.

PENIS CAPTIVUS.

DR. J. R. W. STEPHENS (Withington, Manchester) writes: I have been asked to report the following two cases as being of interest: (1) During the latter part of 1918 I was called to see a warrant officer, R.N., aged about 54. The penis was enormously swollen and oedematous. There was no pain and no gangrene. The bladder was moderately full. The cause was an ordinary gold wedding ring. His explanation was that his wife had put it on him during the afternoon whilst he was asleep in a chair. It was possible to insert a director under the ring, but a Gigli's saw not being available, the man was sent to hospital, where the ring was removed; he made an uneventful recovery. (2) On March 31st, 1921, at 3.30 a.m., an unmarried man, aged 26, called, stating he was "in great trouble." He was found to be a case of "penis captivus" in the orifice of a large stone hot-water bottle, which still contained warm water. It was not possible to withdraw the organ, which was tightly constricted at its proximal end. With an ordinary nail hammer the bottle was broken by the second blow, and the distal end of the penis found to be swollen and oedematous. A third blow from the hammer removed the constriction, and the penis returned to normal, except for slight bruising, in two days. In this case also there was no complaint of pain.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, 38, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

501 Infantile Scurvy

COMBY (*Bull. et Mem. Soc. Med. des Hop. de Paris*, March 3rd, 1921) states that though infantile scurvy has been familiar to pediatricists since the description given by Thomas Barlow in the *Medical-Chirurgical Transactions* in 1883, general practitioners are too apt to overlook it. From an experience of 72 cases he has found that in 9 out of 10 patients the disease has not been recognized before the child was brought to him. Since the war infantile scurvy has become more frequent from two causes. (1) The scarcity of fresh milk and the necessity of employing preserved milk and various infant foods. (2) Failure on the part of the practitioner to recognize the symptoms of scurvy and an ignorance of its causes and neglect of prophylaxis. The diagnosis is established by the three following points, which should always be borne in mind in the case of a child who has been ailing for some little time and has been treated by various methods without success: (1) Artificial feeding for six, eight or ten months with sterilized or condensed milk or infant foods. (2) Pains in the bones, manifested by loss of power in the lower limbs and crying when they are moved—a sign invariably present. (3) Ecchymoses in the gums. This sign, which is pathognomonic, is unfortunately not constant. It was absent in 16 out of Comby's 72 cases, or in 22 per cent. Prophylaxis consists in giving a child who has been fed on sterilized or condensed milk for some months a small quantity of orange juice, grape juice, or lemon juice sweetened with sugar, every day. Treatment consists in substituting boiled fresh milk for preserved milk and giving from 1 to 3 teaspoonfuls of orange, grape or lemon juice daily.

502. The Hydrocephalic Form of Cerebro-spinal Meningitis in Infants

ACCORDING to CALSSADE and REMY (*Paris med*, February 12th, 1921), infection of the cerebral ventricles is a frequent cause of the failure of specific treatment in cerebro spinal meningitis. It may be observed at all ages, but it is of most interest in infants, in whom it is characterized by definite signs and symptoms, instead of being latent as in the adult, and is more amenable to treatment. A characteristic feature of the hydrocephalic form of cerebro spinal meningitis in infants is the long duration of the latent stage, the condition being at first mistaken for gastric derangement and respiratory catarrh. The development of hydrocephalus, which is invisible in the adult owing to the inextensibility of the skull, is shown in the infant by progressive increase in size of the skull, widening of the fontanelles, separation of the sutures, softening of the skull bones (craniotables), lowering of the eyeballs, and development of a well marked venous circulation on the scalp. The anterior fontanelle is in a condition of permanent tension and does not sink down, even when cerebro-spinal fluid is withdrawn by lumbar puncture and all pulsation in it ceases. As regards treatment no benefit can be derived from lumbar puncture or upper vertebral puncture, the only method of any avail is puncture of the ventricles. The quantity of fluid to be withdrawn varies with the case, the more turbid the fluid the greater the amount to be removed. The amount of serum to be injected depends on the amount of cerebro spinal fluid removed. The injections should be made alternately into each ventricle every other day. When possible it is advisable to perform cerebro spinal lavage with antimeningococcal serum. For this purpose lumbar puncture is performed at the same time as ventricular puncture, and the serum is injected slowly into the lateral ventricles until it escapes by the lumbar needle.

503 Infective Processes in the Teeth and Internal Diseases

ANTONILS and CZEPA (*Wien Med. Woch.*, February 21st, 1921) made a systematic study of the connexion of infective processes in the roots of the teeth with internal diseases, and found that of 225 persons suffering from various diseases, such as renal disorders, gastro intestinal complaints, rheumatism including endocarditis, neuralgia, acute respiratory disorders, and cholelithiasis, 148, or 65 per cent, showed chronic inflammatory changes at the roots of the teeth. It was noteworthy that diseases

of which the etiology was not uniform, such as nephritis and rheumatic disorders, formed the bulk of these cases. Hitherto tonsillitis has been regarded as the most frequent cause of these diseases. The writers' investigations, however, showed that septic foci in the teeth were twice as common as chronic tonsillitis in these cases. Now, if chronic inflammatory changes in the tonsils are to be regarded as responsible for the origin of these diseases, it is only logical to attach etiological importance to the much more frequent occurrence of septic foci in the teeth. The connexion of infective foci in the teeth with internal diseases was difficult to prove, as only 39 of the 225 cases submitted themselves to thorough dental treatment. The improvement, however, which resulted in these cases justified the writers in drawing attention to occult foci of suppuration in the teeth and in recommending a careful x-ray examination of the teeth in all diseases, as they are convinced that in a large proportion of these cases the teeth will be found in a morbid condition, and that thorough dental treatment will result in a cure or at least improvement.

504 Oral Symptoms of Disease

Dr. MORGAN (*Lancet*, February 5th, 1921) recently reviewed the oral symptoms which may be found in various diseases. It reads rather like a catalogue, beginning with the appearance of the tongue in various dyspeptic disorders, the writer goes on to mention the scarlatiniform tongue, Koplik's spots, tuberculous ulcers, syphilitic lesions, gonorrheal seen rarely in newborn children and appearing as a yellowish deposit on the oral mucosa. Changes associated with blood diseases—pernicious anaemia, scurvy. Dryness of the mouth in diabetes and pyorrhoea—frequent as a complication in diabetes. Oedema as a complication of trachema. Drug eruptions (usually appearing as herpetic vesicles in the mouth) from antipyrin and quinine; mercurial stomatitis, the blue line of plumbism, various forms of aphthous stomatitis. Actinomycosis, sprue, epulis, affections of the salivary glands, parotitis, various nervous affections, for example, paræsthesia, paralysis, hysterical globus. Amongst disturbances of secretion he mentions sialorrhoea and the rare xerostomia, where there is no salivary secretion. Perforating buccal ulcer may occur as a complication of tabes. Dental trouble—caries, first dentition, rickets, syphilis, scrofulosis, and finally brief reference is made to factor of the mouth, which is usually of local origin—due to tonsillary or dental trouble.

505 Injections of Turpentine in Pemphigus

BRENNING (*Dent. med. Woch.*, February 17th, 1921) has treated three cases of pemphigus with injections (presumably subcutaneous) of turpentine, and he expresses great satisfaction with the results. The improvement effected was the more remarkable as, in his experience, pemphigus is a very intractable condition. One of his cases was that of a servant girl, aged 22, who was admitted to hospital with severe pemphigus. Almost the whole body was covered by vesicles, so that she could not lie comfortably in any position. Her mouth, the tongue included, was also involved, and she had great difficulty in taking food. After three weeks of futile treatment with various remedies, 0.5 c.c. of a 20 per cent solution of oil of turpentine was injected, and the same dose was repeated two days later. A third injection, this time of 1 c.c., was given three days later. After the fourth injection no new eruptions occurred, but convalescence was protracted owing to the slow healing of the erosions left by the vesicles. The author adds that the injections caused no discomfort and he believes that they were the cause of the patient's recovery in every case.

506 Concentration of Blood, Fever, and Loss of Weight in the Newborn

UTHEIM (*Nord. Med. Tidn.*, August 1st, 1921) has examined the records of 400 confinements in a maternity hospital, and has found that in 21 per cent the temperature of the newborn infants was raised. The average loss of weight during the first few days of life was about 300 grams, and the frequency of fever increased with the amount of weight lost. To determine the changes in the concentration of the blood during the first few days of life the author carried out refractometric

examinations of the blood drawn from the heels of twenty-eight normal infants, the test being repeated daily till the ninth day. Little or no change was observed in the concentration of the blood. No constant relation could be found between the loss of weight and the concentration of the blood, nor between this and a rise of temperature. The author concludes that the loss of weight is a perfectly physiological and necessary process, representing as it probably does the discarding of fluids which have become superfluous under the conditions of extrauterine life. As for the rise of temperature, several possibilities are discussed, and the author suggests that the causes may be different in different cases. One of these causes is probably the newborn infant's yet imperfect heat-regulation mechanism. Toxic absorption from the intestine and the excretion of certain substances by the kidneys may also cause a rise of temperature.

507. Acute Arthritis in Infants.

JOHNSON (*Amer. Journ. of Dis. of Children*, February, 1921) records the study of 73 consecutive cases of acute arthritis admitted to hospital during the last fifteen years. The invasion of joints and periarticular tissues by pyogenic organisms is not rare, the joint inflammation being usually secondary to an infection of the epiphysis, though in many instances the inflammation spreads from the epiphysis to the periarticular tissues without affecting the joints proper. Considerable swelling, with or without suppuration, tenderness, redness and a great amount of induration, were the clinical manifestations. In only 32 of the cases could there be said to be any definite source of infection. Males predominated, and in the females vaginitis did not appear to be as common a cause of arthritis in infants as is generally supposed. The younger the infant the greater seems to be the susceptibility to purulent arthritis. The principal organisms responsible for infection were found to be the staphylococcus and the pneumococcus. The streptococcus and gonococcus were found to be more prone to affect multiple joints, while the pneumococcus seemed limited to one or two joints. Prognosis is not good and is affected by age, the older the child the better being the chance of recovery.

508. The Renal Test Meal.

ACCORDING to FROMM (*Albany Med. Ann.*, November, 1920), the renal test meal consists of a carefully composed dietary regimen of twenty-four hours' duration in three separate meals. It contains approximately 13.5 grams of nitrogen, 8.5 grams of sodium chloride, 1,760 c.cm. of fluid, and a considerable quantity of purin material in the form of meat, soup, tea, and coffee. All these substances act as diuretics, and it is on the mode of excretory response to such stimuli that the interpretation of the test depends. The test meal yields the following results in the different types of renal disease: (1) Chronic interstitial nephritis. In early cases nocturnal polyuria is usually the first sign of renal impairment. In advanced degrees of interstitial nephritis the following factors indicate renal insufficiency: (a) Marked fixation and lowering of the specific gravity; (b) a diminished total output of sodium chloride and nitrogen; (c) a tendency to polyuria for the whole twenty-four hours; (d) a night urine showing an increase in volume, lowering of the gravity, and a concentration of nitrogen under 1 per cent. (2) Chronic parenchymatous nephritis. The characteristic findings in these cases are as follows: (a) The specific gravity tends to be high and fixed; (b) there is a diminished output of sodium chloride and water; (c) nocturnal polyuria is present; (d) there is practically a normal excretion of nitrogen. (3) Renal congestion resulting from cardiac decompensation. The test meal in such cases is followed by the following results: (a) A fixation of gravity about the level of 1020; (b) a diminished output of sodium chloride; (c) a diminution in the amount of the day urine; (d) a normal nitrogen elimination; (e) a normal night urine.

509. Subcutaneous Oedema in Sero-fibrinous Pleurisy.

ACCORDING to LUSSANA and ARRIGONI (*R. Policlinico*, Sez. Prat., February 14th, 1921), who record an illustrative case, subcutaneous oedema may be caused by a non-suppurative sero-fibrinous pleurisy. The oedema may be confined to the base of the thorax, and to one side only, or be unilateral and extend from the base of the thorax to the sacrum and lower part of the trunk, presenting all the characters of oedema due to stasis. The explanation of the oedema, according to the writers, is to be found in a fibrino-plastic effusion occurring in the mediastinum, causing compression, traction, and subsequent occlusion, to a greater or less extent, of the veins in the posterior mediastinum.

SURGERY.

510. Simulation of Appendicitis by Acute Anterior Poliomyelitis.

DUBS (*Schweiz. med. Woch.*, March 17th, 1921) records three cases occurring in the same month in which the symptoms of acute anterior poliomyelitis simulated those of acute appendicitis so closely that this was diagnosed and laparotomy performed. Only a few days after the operation did flaccid paralysis develop and the true nature of the disease become evident. While admitting that these cases showed blunders on the part of the surgeon, the author insists that the rule of operating on acute appendicitis at the earliest possible stage is excellent, although it entails the inclusion of a certain number of mistakes in the surgeon's list of laparotomies. These mistakes must be regarded as far less serious than deferring operations for appendicitis till the diagnosis is invariably placed beyond doubt. In the author's cases the local signs conformed in a remarkable degree to the well recognized clinical picture of appendicitis; there was marked tenderness with rigidity at McBurney's point, and sudden release of pressure on the abdomen provoked lively pain. But, he admits, there were certain features of the general symptomatology in the first case which should have made him give pause. The patient, an unmarried woman of 21, complained of general lassitude, headache, and excessive perspiration. Her temperature was high from the outset (102.2°). The author subsequently remembered that he had never seen a patient suffering from acute appendicitis complain of headache and excessive perspiration, and he considers a high temperature early in the disease as a rare concomitant of acute appendicitis. He also refers to the simulation of acute appendicitis by encephalitis, a case in point being recently recorded by Seidel (*Munch. med. Woch.*, No. 7, 1921, p. 219).

511. Vaccine Therapy of Gonorrhoea.

HERMANS and VAN DEN BRANDEN (*Le Scalpel*, January 8th, 1921), after discussing the various vaccines (English, French, Italian, German, and Belgian) used in the treatment of gonorrhoea and its complications, conclude that this method of treatment is still in its infancy. It is true that in some of the complications of gonorrhoea, especially as regards epididymitis, excellent results have been obtained, but the chief enemy, the gonococcus, in its site of election, the urethral mucosa, too often escapes. Perhaps one reason is that the organism exists so superficially and is not sufficiently in contact with the blood stream, so that mechanical means of disinfection are always necessary adjuncts in treating simple gonorrhoea. On the other hand, when complications arise, vaccine therapy is the best mode of treatment. By this means many a case of epididymitis can be shortened and the secondary results prevented.

512. Acriflavine Irrigation in Gonorrhoea.

MANN (*Med. Record*, January 22nd, 1921) urges acriflavine irrigation in the treatment of gonorrhoea, the dyestuff being highly gonococcidial and penetrating to the muscular layers of the urethra. A solution 1 in 4,000 is bland and non-irritating, and even when the urethritis is severe its use causes no pain or discomfort. Two ounces of a stock solution 1 in 500, containing a drachm of sodium chloride to each two ounces, diluted up to one pint with water at body temperature, yields a 1 in 4,000 solution of acriflavine in a physiological saline solution, and this should be used once a day, retaining the solution in the anterior urethra for ten minutes at the end of each irrigation. This, in conjunction with drinking ten to twelve glasses of water daily, constitutes the entire treatment. If the second urine becomes cloudy, indicating posterior involvement, intravesical lavage is used, unless the symptoms are hyperacute, in which case anterior irrigations alone are used, until the severe symptoms abate, prior to instituting the intravesical irrigation. Results, which were controlled by cultures after provocative injection and massage, were more than ordinarily satisfactory.

513. Urinary Antiseptics

DAVIS (*Amer. Journ. Med. Sciences*, February, 1921) summarizes the results of an investigation of the antiseptic properties and the renal excretion of 204 aniline dyes. There is no drug which is ideal for internal urinary antiseptics, but of the 204 aniline dyes investigated 61 possessed antiseptic properties in agar, and 23 of these were efficient when added to voided urine. Forty-four dyes showed a selective action against various organisms, the colon

bacillus always being more resistant than the staphylococci, and only 24 inhibited the colon bacillus in urine in a dilution of 1 in 1,000. Antiseptic action is shown in higher dilution in alkaline than in acid urine so that the dyes are more efficient in urine of a reaction which renders motropin inert. Fifteen of the dyes were antiseptic in urine, excreted by the kidneys, and relatively non-toxic, but with only two of these (proflavine and acriflavine) did excretion of antiseptic urine follow intravenous administration. Dyes of the triphenylmethane xanthone, acridin, and azin groups afford most promise of value, and these experiments give reasonable expectation that a dye clinically suited as an internal urinary antiseptic may be discovered or synthesized.

514. Ocular Manifestations of Epidemic Encephalitis

HOLDEN (*Arch. of Ophthalmology*, March, 1921) has collected the eye symptoms noted in 100 consecutive cases of epidemic encephalitis at the Mount Sinai Hospital in New York. He tabulates his results as follows: (a) *Optic nerve symptoms*. Blurred optic discs in four cases, true papill oedema in one case. (b) *Oculo motor and abducens nerve symptoms*. Ptosis: both eyes, forty five cases; one sided, eleven cases; total fifty six cases. Extrinsic muscles of the eyeball: paralysis of both external recti, seventeen cases; paralysis of right external rectus, fourteen cases; paralysis of left external rectus, thirteen cases, total forty-four cases. Paralysis of both superior recti, one case; paralysis of both internal recti, four cases, paralysis of one internal rectus, one case; paralysis of both internal and external recti, two cases; total third nerve paralysis, one case, paralysis of conjugate dextroversion of both eyes, two cases, in all, weakness of oculo motor muscles which would give rise to diplopia was present in fifty five cases. Nystagmus was present in thirty two cases. In regard to the condition of the pupils, there was an irregularity in fifteen cases and inequality in twenty cases; sluggishness or absence of the light reflex in thirty five cases, in thirteen of which the convergence reflex was also sluggish. Irregularity and inequality of the pupils, not associated with sluggishness, was noticed in seven cases. There was weakness of accommodation in both eyes in one case. (c) *Facial nerve symptoms*. There was weakness, chiefly of the lower face and rarely leading to lagophthalmos, of both sides in twenty four cases, and of one side in forty nine cases, a total of seventy three cases. It will be seen that the results are very closely similar to those reported by other observers. The total brings out the great rarity of fundus lesions in cases of epidemic encephalitis.

515. Treatment of Ozaena.

BRUZZI (*Arch. ital. di otol., rinol., y laringol.*, Fasc. v and vi, 1920) states that the factor in ozaena is due to the decomposition of protein bodies by means of bacterial tryptic ferments with formation of mercaptan and other sulphur compounds, and that the Perez bacillus, which is supposed to be the cause of ozaena, plays the principal part in this decomposition. In the nasal cavities there is normally a rich bacterial flora, consisting, among other germs, of glycolytic bacteria, so called owing to their power to ferment sugar. The object of the recently introduced glucose treatment of ozaena is to increase the activity of these micro organisms in the fermentation of carbohydrates, to the detriment of the Perez bacillus. Moreover, tryptic ferments require an alkaline medium to act on protein substances, whereas the fermentation of sugars is accompanied by the formation of acid, whereby the proteolytic activity of the Perez bacillus is inhibited and the organism itself destroyed. The treatment consists in first removing the crusts by irrigation with an alkaline solution or spray and then applying a solution of glucose or honey on swabs three or four times a day to all parts of the nasal cavity. In 22 cases so treated by Bruzzi very satisfactory results were obtained. In 10 patients glucose was used and in 12 honey, the results being equally good in both cases. The duration of the treatment ranged from fifteen to thirty days.

516. Suction in Oto-laryngology.

WAGERS (*Thyngentische Gazette*, February 15th, 1921) points out the value and technique of the application of suction in the local treatment of suppurative inflammation involving the ear and nasal accessory sinuses as a means of obtaining cleanliness of the part treated, and, by producing local hypercemia, of promoting healthy tissue reaction. Three types of apparatus are described—an electrical suction pump, the Brawley water suction pump, and an ordinary rubber bulb. The method is most often useful in the diagnosis and treatment of nasal accessory sinus disease,

and certain anatomical and physical points which have to be borne in mind for its successful accomplishment are mentioned. For the removal of blood from the throat during operation suction is most useful, providing a clear field of view and preventing the aspiration of blood and secretions, thereby minimizing the risk of pneumonia and lung abscesses. Although a certain number of cases will clear up in a few days after treatment by suction alone, the method cannot take the place of surgery where needed, but it assists in thoroughly removing purulent secretions, and in carrying away bacteria and their products from the involved area. It is equally applicable in chronic otitis media as in the acute condition, care being taken not to exercise too great a negative pressure, and in the post-operative treatment of suppurating mastoids it may be employed to remove all pus from the wound.

OBSTETRICS AND GYNAECOLOGY.

517. Persistent Vomiting during Pregnancy

VAUGHAN and MEYER (*La Gynéc.*, January, 1921) remark that in the exceptional cases in which vomiting continues after the fourth month of pregnancy search should be made for an etiological factor other than a pregnancy toxæmia. As an illustration they relate the case of a primipara, aged 20, in whom emesis persisted and became increasingly severe from the fourth to the sixth month. In spite of treatment by strict dieting, together with subcutaneous and rectal injections of "adrenalized" serum, vomiting continued to occur almost hourly. The findings at laparotomy were normal, and the injection of serum from a healthy pregnant woman failed to control the vomiting. A few days after induction of abortion, incoordination of speech and of movement was noticed, together with nystagmus; lumbar puncture gave a clear fluid exhibiting hyperalbuminosis, but no cytological reaction. The patient succumbed, in a state of coma, shortly after an exploratory trephining had been performed. At autopsy there was found a cerebellar tuberculoma (the size of a nut) in process of caseation.

518. Indirect Expulsion of the Placenta

BAER (*Journ. Amer. Med. Assoc.*, February 26th, 1921) considers that any method of ending the third stage of labour which does away with handling the uterus is desirable, and he describes an indirect method by utilizing the full power of the abdominal muscles to drive the uterus down against the separated placenta and so expel it. After a waiting period averaging half an hour, with the uterus in mid line, and while at the height of a contraction, the abdominal wall is grasped by one or two hands crosswise above the umbilicus, the fingers on one side beyond the rectus and the thumbs on the opposite side also beyond the rectus. The recti are then pulled together and firmly held, so that all the slack in the relaxed overstretched wall is taken up. The patient is now urged to bear down, her successful co-operation being felt by the contracting of the recti and their tendency to pull apart, which is prevented by the grip of the hands, so that the force is properly transmitted downwards against the uterus and the placenta is expelled as in spontaneous cases. The method operates only after separation has occurred, but its application is harmless if separation has not yet taken place. Of 277 cases in which the method was tried it was successful in 249 (90 per cent.).

519. Treatment of Fever following Abortion

LATZKO (*Zentralbl. f. Gynäk.*, March 26th, 1921) returns to the discussion of the relative merits of immediate curetting and of expectant treatment in cases of pyrexia following abortion. While admitting that expectant treatment may prolong the period of convalescence, he is convinced that as a result of active treatment the percentage mortality is increased. At the Bettina Pavillon in Vienna post-abortion fever was treated actively from 1910 to 1914, expectantly from 1915 to 1920. During the former period the percentage mortality was 5 per cent. in cases with temperatures from 98.6° to 100.4°, 11 per cent. in cases with temperatures from 100.4° to 101.3°, and 14.8 per cent. in cases with temperatures above 101.3°, after the adoption of expectant methods the percentage mortality was reduced in each group, the figures being 3.6 per cent., 7.8 per cent., and 10 per cent. respectively. Special interest attaches to these statistics in that they relate to periods of five years, and that about 4,000 cases were recorded during each period. HALBAN (*Ibid.*), who in 1,595 cases of febrile

abortion, treated actively, had a mortality of 3.1 per cent., is not convinced of the superiority of expectant treatment, and criticizes the statistics which have been published. In particular, he points out that fatal cases are in the majority of instances (75 per cent. in his series) drawn from among those patients who on admission to hospital already have some severe extrauterine complication; the excessive mortality among such cases should be taken into account when comparing the comparative death rates associated with different modes of treatment.

520. Colostrorrhoea in Pregnancy.

DEL VECCHIO (*Il Policlinico*, Sez. Prat., February 21st, 1921) alludes to the case of galactorrhoea recently reported by Luzzatti (vide *Epitome*, February 26th, No. 278), and relates the case of a primipara, aged 22, who in the fifth month of pregnancy developed a profuse flow of colostrum from both breasts, followed by erosion of the nipples. In the seventh month of pregnancy the flow ceased without any appreciable cause. Pregnancy went on to term, and labour and the puerperium were physiological. Unlike Luzzatti's case, galactorrhoea did not occur after delivery, but the secretion of milk, which set in as usual on the third day, was quite normal.

521. Transvesical Operations for Vesico-vaginal Fistula.

MARION (*La Gynec.*, December, 1920) related to the Société de Chirurgie the case of a woman who, in spite of five previous attempts at operative repair, had a large vesico-vaginal fistula, the cervix projecting within the vesical cavity. Operation by the transvesical route proved successful in this as well as in twelve other cases operated on by Marion. All those who contributed to the subsequent discussion were agreed as to the usefulness of the transvesical approach, especially in the case of fistulae situated relatively high in the vagina.

PATHOLOGY.

522. Prevention of Anaphylactic Shock.

BRODIN and RICHET (*C. R. Soc. Biologie*, February 12th, 1921), in comparing the blood changes in anaphylactic shock with those found in what has been called "peptone shock," find many points of similarity, such as fall of arterial pressure, leucopenia, hyperviscosity, decrease of coagulability, and others, though there are certain differences. Knowing that a previous injection of peptone immunizes against a subsequent injection, they sought to find if it was possible to produce a cross immunity and thus prevent anaphylactic accidents. Six dogs were therefore given an intravenous injection of 50 to 100 c.cm. of horse serum, and after one or two months 10 to 15 c.cm. of peptone per kilogram of body weight were injected rapidly into the veins, and an hour afterwards they were tested with 50 to 100 c.cm. of horse serum. The peptone injection was always well tolerated. The testing dose of horse serum was followed by only very slight symptoms, whilst of the control animals, not treated with peptone, 4 out of 7 showed severe or fatal crises. Thus the injection of peptone may attenuate considerably the danger of anaphylactic shock.

523. The Pathology of War Oedema.

WELTMANN (*Wien. Arch. f. inn. Med.*, December 15th, 1920) records three cases of war oedema in which atrophy of the pancreas was found at the autopsy. He draws attention to certain resemblances between war oedema and diabetes mellitus—namely, polyuria, hyperglycaemia, the increase of acetone bodies in the blood, increased excretion of creatin, uric acid, ammonia, and amino-acids, the deficiency of glycogen in the liver, the readiness with which the oedema can be produced by sodium bicarbonate, and finally the coma preceding death. Weltmann considers that the oedema disease is closely allied to the marasmic condition accompanied by dropsy which occurs in children as the result of alimentary disturbance. He regards the atrophy of the pancreas in his cases as an expression of a constitutional deficiency.

524. Picrocarmine Staining of Sections.

JENSEN (*C. R. Soc. Biologie*, February 12th, 1921), gives a method of preparing this old stain which is applicable to paraffin and celloidin sections. Picrocarmine staining was difficult, even with frozen sections, but when it was

brought off successfully it was a beautiful method. Jensen who has tried various ways of getting good results, recommends the following:—First solution: dissolve 1 gram of carmine and 0.1 gram of magnesium oxide in 50 c.cm. distilled water, boil for five minutes, filter when cold, add 0.5 c.cm. of carbolic acid. Second solution: 0.5 gram of picric acid and 0.5 gram magnesium oxide in 50 c.cm. of distilled water, boil for five minutes, and when cold. Mix these two solutions and add slowly, with shaking, 10 c.cm. of 1 per cent. solution of picric acid in distilled water. The clear resultant liquid keeps indefinitely, stains the nuclei intensely with paraffin sections, especially after fixation in sublimate or alcohol, but it also acts well after formalin fixation. It may be used in conjunction with Claudius's modification of Gram's stain. After removal of the paraffin and washing in alcohol the sections are stained for two or three minutes in 1 per cent. aqueous solution of methyl violet, and, after washing in water, stained with the picrocarmine solution for three to five minutes; the stain is poured off and the sections cleared with filter paper, after which they are differentiated in aniline oil containing a little picric acid until they show rose colour. The bacteria in the sections are stained black, the nuclei red, the protoplasm orange, muscle red corpuscles yellow, and the connective tissue rose.

525. Bence-Jones Proteinuria.

WALTERS (*Journ. Amer. Med. Assoc.*, March 5th, 1921) had the opportunity of studying three cases of Bence-Jones proteinuria. The first patient had an old complaint suggestive of duodenal ulcer, but there was no demonstrable lesion of any of the bones, either on physical examination or by roentgenographic study, apart from the characteristic protein in the urine. Indeed, there was no abnormality found. The second case was one of generalized carcinomatosis with involvement, and the third case was one of multiple myeloma, in which the peculiar protein is generally found. The author found that the quantity of Bence-Jones protein excreted is independent of the protein intake, as there was an approximately constant excretion for three-hour periods irrespective of changes in diet, and that the amount excreted during night-time when no food is taken is only slightly less than the amount excreted during the day. There was no constant relation between the quantity of Bence-Jones protein and total urinary nitrogen.

526. Tumours of the Auditory Nerve.

ACCORDING to FUMAROLA (*Il Policlinico*, Sez. Mc February 1st, 1921), who records two illustrative cases, is not justifiable in the present state of our knowledge to make any other diagnosis than that of a tumour of the ponto-cerebellar angle without determining whether it is primary or secondary. Once the diagnosis of a tumour of this situation is made, surgical intervention is called for even when the signs point to a secondary growth, as may happen, as in one of Fumarola's cases, that the tumour is really primary and therefore should be removed. Fumarola also draws attention to the medico-legal importance of the close relation between trauma and development of endocranial tumours. In one of his cases the symptoms developed three weeks after the patient had been wounded on the head and elsewhere by the explosion of a bomb, so that the disease might properly be regarded as a war injury.

527. The Metabolism in Vascular Hypertonus.

HITZENBERGER and RICHTER-QUILTNER (*Wien. Arch. f. inn. Med.*, February 15th, 1921) during the last few years have made a systematic examination of the blood sugar in a number of cases of hypertonus. The cases were divided into three groups: (1) Primary hypertonus; (2) secondary hypertonus due to chronic glomerular nephritis; (3) hypertonus associated with diabetes mellitus. They found that hyperglycaemia was a regular occurrence both in primary and secondary hypertonus. This form of hyperglycaemia differed from that met with in diabetes mellitus chiefly in being independent of an alimentary factor. It was therefore not due to a disturbance of sugar assimilation but to persistent overproduction of sugar. In cases in which vascular hypertonus was associated with diabetes including hyperglycaemia was out of all proportion to the sugar excreted in the urine. In vascular hypertonus there was frequently also an excess of uric acid in the blood. The writers think that the syndrome of hypertonus, hyperglycaemia, and hyperuricaemia may depend on an increase of secretion of adrenaline.

A Clinical Lecture ON ACUTE INFECTIVE ARTHRITIS.

DELIVERED AT GUY'S HOSPITAL.

BY
F. J. STEWARD, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL.

On June 16th last, in consultation with Dr. Montgomery of Bromley, I saw a little girl, aged 4, with a swollen left knee.

The history was that the child had always been healthy and robust, but just recently had not seemed quite herself, also she had been bothered with "heat spots," some of which had been scratched and had become pustular. A week previously she complained that her knee hurt her when she was being put to bed. The next morning the knee was more painful. Dr. Montgomery saw her and found the knee a little swollen and slightly tender, but she moved it freely. The temperature was 100 F. No other joints were affected. A splint was applied and small doses of sodium salicylate ordered. During the succeeding days the knee swelled more and became more painful, the temperature rose to 100 or 101°, her general condition was not so good, and sleep was much disturbed by pain.

When I saw her, on the seventh day, she was looking ill and tired. The knee was tense and obviously contained fluid. It was tender, but not extremely so, and, moreover, the thigh was distinctly swollen. There was no swelling behind the knee, and no tenderness on pressure over femur or tibia. Attempts at moving the knee obviously caused pain.

Here, then, was a child with a single swollen, tender, and painful joint associated with pyrexia and general illness, and becoming progressively worse. These are the signs and symptoms of acute arthritis, which in this case was clearly not rheumatic, as no other joints were affected, and the administration of salicylates had produced no improvement. It was therefore probably due to a pyogenic infection.

Now let me remind you of the ways in which a joint may become infected. They may be arranged conveniently in four groups:

1. From the exterior, due to accidental and gunshot wounds.
2. By spread from neighbouring parts, especially in cases of acute infection of one of the bones forming the joint.
3. By metastasis from an infective process in some other part of the body. In one case I shall mention later there was an infected graze over the knee, in another the source was probably a septic tonsil.
4. In general blood infection. Here infection of one or more joints is, of course, a frequent occurrence.

Now this child had no wound of the joint, and there was no evidence of infection of either of the bones or of any other part near the joint. There was therefore no reason to suspect a spread of infection to the joint from the neighbouring parts, and there was no evidence of a general blood infection. The case, therefore, did not belong to Group 1, 2, or 4. There were, however, the spots that had been scratched, which constituted a very possible source for a metastatic infection. I therefore placed the case in Group 3.

In such circumstances clearly the next step was to confirm the diagnosis by means of the exploring syringe. This I advised, but as it was desired that Dr. Still should see the child, there was a delay of a few hours. Then, under an anaesthetic, I drew off a syringeful of thick yellow pus.

When a joint becomes infected by pyogenic organisms, the blunt of the attack is borne in the first instance by the synovial membrane, which puts up for a time a very stout resistance. This primary stage in the process is of the very first importance, for, while it lasts, suitable treatment usually results in complete recovery.

After a while, however, the infection spreads to the other structures forming the joint, and also to the parts beyond the joint, so that cartilage and ligaments are destroyed, and the joint becomes converted into an abscess cavity. Further abscesses form outside the joint and spread in various directions. If, as the result of treatment after this stage has been reached, the patient survives, the best result that can be hoped for will be a

joint more or less completely ankylosed, and very possibly dislocated, owing to destruction of ligaments.

In the case we are considering, then, much depended upon whether the resistance of the synovial membrane had been so far equal to the occasion or not, and it was necessary that such treatment should be adopted as would aim at supporting that resistance in every way possible.

I want particularly to lay stress upon this very remarkable local characteristic of the synovial membrane of a joint which enables it to deal with infection probably even more efficiently than the peritoneum. War experience emphasized this, for results clearly show that the best way to treat a joint infected by a bullet or piece of shell or clothing is to remove the foreign body, cleanse the joint so far as possible, close the wound, and let the synovial membrane do the rest. In a large majority of the cases treated in this way a perfect cure resulted.

Now the synovial membrane may be assisted in the exercise of its functions by treatment, that is to say:

1. By letting out the pus. By so doing the blood supply to the synovial membrane, which must be greatly interfered with by the direct pressure of the pus, will be restored, in addition to getting rid of the local and general poison.

2. By keeping the limb at rest by the application of a suitable splint with extension. The extension is very necessary in order to overcome the pain and so render the patient comfortable and able to rest. Without it the muscles tend to spasm, which results in pressure between the inflamed and painful joint surfaces, and also in those sudden terrible pains which occur just as the patient falls asleep and the contracted muscles relax. In the knee-joint the best appliance is a Thomas knee splint which is suspended in a cradle, extension being obtained by means of a weight in the ordinary way.

3. By the injection of antiseptics into the joint. The necessity for this is by no means certain, and, although it has been held to be of great service by some surgeons, its value must be, to a large extent, problematical. The substances most favoured are a 2 per cent. solution of formalin in glycerin, the use of which was strongly advocated by Murphy, and ether, which has also been largely used, especially during the war.

But, in order that this treatment may have a chance to succeed, it must be applied in good time, and before the barrier imposed by the synovial membrane has been seriously broken through, otherwise the results are likely to be disastrous.

This implies a correct diagnosis at the earliest possible moment, and, to this end, I wish to insist upon the extreme importance of the use of the exploring syringe without delay, in order to clinch the diagnosis whenever you have occasion to even suspect that a joint is infected. By this means, and this means only, will the best results be obtained.

I treated the case we are considering on these lines. An incision was made on the inner side of the patella and a large quantity of thick pus evacuated. The joint was then thoroughly washed out with warm mercury bichloride solution of a strength of 1 in 4,000. It was noted that the synovial membrane was quite pallid when first seen while the pus was being evacuated, but very quickly became

red, as I have mentioned, and had interfered with the free supply of blood to the part. The capsule of the joint was then closed with catgut sutures, the skin wound sutured, and dressings and splint applied.

During the next two days the child was markedly better, the temperature was only slightly above the normal, she took food well, and made no complaint of pain. The bacteriological report upon the pus was that a pure culture of *Staphylococcus aureus* had been grown from it.

When I saw the child again, on the third day, the joint was less tender and the thigh less swollen, but as there was some fluid in the joint I explored it. The syringe, however, only withdrew a small quantity of clear fluid, slightly blood stained, which was very remarkable in view of the condition only three days before; it showed how well the synovial membrane was doing its work. Nevertheless, in order that we should feel that we had done everything that could be done, whatever happened later, I then injected into the joint 2 c.cm. of 2 per cent. formalin in glycerin.

Subsequent progress was perfectly satisfactory, except that two small stitch abscesses formed, each accompanied by a slight degree of pyrexia. The joint remained a little swollen for some time, but no more fluid formed and the child's general condition rapidly improved. The extension was kept on until all swelling had disappeared—that is, until the end of July.

After this the child was taken to the sea wearing a back splint. This was kept on for two months, when I found the knee normal in appearance and without heat or tenderness. Flexion was perfectly free and smooth through about thirty degrees; after that there was slight resistance. I ordered the limb to be massaged, the splint to be gradually discarded, and the limb used more and more, and although I have not seen the child again, I understand that the knee now moves quite freely and painlessly and is completely recovered.

I wish to draw attention to a few further points regarding this case. The first is that from the time the joint was emptied of pus, and the extension applied, the child never again complained of pain. Consequently she slept well and soon regained her appetite, factors contributing in no small degree to her recovery.

The next point is that the organism in this case was *Staphylococcus aureus*. This is, I think, unusual, but is in conformity with the view I expressed that the infection came from the skin pustules. Of three other metastatic cases that I shall describe, the organism in one was a streptococcus, in the other two no organism was found. The third point is that the disease was not extremely acute, for the joint was not opened until the seventh day and yet recovered completely. This is what usually happens in metastatic cases, and is to a less extent, perhaps, true of some other cases. For instance, I had under my care in France an officer who had had a fragment of shell lodged in the back of the upper end of the tibia. When he came under my care he had been wounded a week, and there was a good deal of fluid in the knee-joint, but it was not particularly painful and not at all tender. He was seen by two consultants, both of whom expressed the opinion that the fluid was not pus and that the joint should not be interfered with. However, I thought it wiser to explore the joint, and on so doing found the fluid to be pus.

The next case had reached a slightly more advanced stage before the joint was explored, nevertheless the result is perfect, as you will see.

Joan C., aged 4 months, was admitted to Guy's Hospital on January 7th, 1920, with a swollen right elbow of several days' duration. The child was obviously ill; the temperature was raised and the elbow swollen, tender, and clearly extremely painful on attempted movement. Mr. Slesinger operated upon the case for me. The joint was opened, and a quantity of pus let out. After washing out the joint the incision was closed and a splint applied.

The child was better for several days, then the temperature again rose, the arm became more painful, and a fluctuating swelling appeared in the arm, the elbow itself remaining normal in size. The swelling was explored, and found to contain thick pus, but on free incision no connexion with the elbow-joint could be detected, and after drainage for a few days there was no further trouble. The bacteriological report upon the pus from this case states: "No growth obtained after several plantings."

The subsequent history was uneventful, and I am now able to show you the child ten months after the joint was opened. You see that she looks quite healthy, and that the arm and elbow move perfectly freely in all directions. In fact, but for the two scars, it would not be possible to say that the arm had ever had anything wrong with it.

This case differs from the first in that an abscess developed outside the joint. But you will note that with the formation of this abscess there was no refilling of the joint with pus, neither was any connexion between abscess cavity and joint cavity discovered at the second operation. It is quite clear, therefore, that there was no direct continuity, but that the periarticular abscess had originated in some other way. Examination of portions of synovial membrane from infected joints has proved that micro-organisms may be present in the subsynovial tissue without any massive ulceration or perforation of the synovial membrane having taken place. A proportion of the organisms in an infected joint therefore evade the attentions of the synovial membrane and escape into the tissues beyond, where they are either destroyed or cause the formation of pus, as the case may be. This, then, explains the formation of an abscess in this child's arm although

the synovial membrane was not destroyed. The third case is very similar.

A boy, aged 7, was admitted into Guy's Hospital on October 8th, 1920. Eight days previously a brick, thrown at him by another boy, struck him on the left knee and grazed the skin. Next day the knee began to swell and to become painful, and during the succeeding days the pain and swelling increased.

On admission to hospital there was a small septic graze over the front of the left knee; the joint was tense with fluid, very tender, and extremely painful on any attempt at movement; the temperature was 100°, and the boy looked very ill. Under an anaesthetic the exploring syringe drew pus, so the joint was opened, washed out with mercury biniodide 1 in 4,000, the wound closed, and a Thomas knee splint with extension applied.

During the next two days the boy was clearly better, but his temperature remained high (103°), and when, on the third day, I found the knee again swollen, and the bacteriological report stated that a pure culture of *Streptococcus longus* had been grown from the pus, I thought it wiser to explore the joint once more. The result, however, was perfectly satisfactory, the fluid withdrawn being clear serum, slightly blood-stained. In view of the bacteriological report and the high temperature, 15 c.c.m. of antistreptococcal serum were given subcutaneously. After this the boy improved, although the skin incision suppurated slightly, but on October 23rd—that is, fifteen days after the first operation—the temperature shot up to 103° again, and some swelling appeared in the thigh. Four days later it became clear that there was an abscess in the thigh; an incision was made and several ounces of pus evacuated, but no communication between the abscess cavity and the knee-joint, which was now almost normal in size, could be found.

From this time progress was satisfactory, and the boy left the hospital in good health on December 8th, but still wearing a splint.

Unfortunately, no culture was made from the septic graze over the knee, but I feel sure that this was the source of the streptococcal infection of the joint.

Here, as in the last case, an abscess formed outside the joint without any direct connexion, and, in fact, after the joint itself had practically recovered. It was no doubt due to spread of infection through the synovial membrane.

To recapitulate the main features of these three cases: they all were children, the arthritis in all was metastatic in origin; they all illustrate the remarkable power of the synovial membrane of a joint to deal successfully with infection; they all show the value of using the exploring syringe without delay, and they were all treated by washing the joint out through a free incision, complete closure of the incision, splinting, and extension. Finally, they all recovered—two with complete restoration of function; the third is still under treatment.

The next case presents quite a different picture.

A little girl, aged 8, was admitted to hospital after three days' illness, with a brassy tender swelling involving the lower half of the right thigh. She was extremely ill, with very rapid pulse and temperature 104°. A diagnosis of acute osteitis of the femur was made, and she was operated upon immediately. A large subperiosteal abscess was opened, and the lower part of the bone, which was found to contain pus, was rapidly laid open and packed lightly with gauze. The next day the child was better, but on the following day she was delirious, and the knee-joint was found to contain pus.

The limb was immediately amputated through the middle of the thigh, but she died the following day, abscesses in the myocardium and early pericarditis being found *post mortem*.

This case illustrates the infection of a joint from a neighbouring bone, and you will note the extreme virulence of the disease in comparison with the metastatic cases I have already described. Further, you will observe that as soon as it was found that the knee-joint was infected the limb was amputated. This course was adopted because the child was already so extremely ill that it was quite clear that she would not be able to deal with an infected joint in addition to her other troubles. In these circumstances an immediate amputation offers the only chance of saving the patient's life, and is occasionally successful in doing so.

In all the cases I have described there were very definite symptoms and signs that drew immediate attention to the affected joint, so that there was, at any rate, no possibility of failure to recognize the seat of the trouble. This, however, is not always the case, for there is another quite definite clinical type of infective arthritis—a condition which might well be described as "quiet" arthritis, since there are no acute symptoms and no pus formation. In fact, the condition is often undiagnosed and unsuspected until the patient is convalescent. Then a joint, more often than not the hip, is found to be disorganized, fixed and very probably dislocated.

I had hoped to show you a boy illustrating this condition, but he was not able to come. He was in hospital three years ago with acute osteitis, and during a long and serious illness he developed, no one knew exactly when, an arthritis of the hip which resulted in a pathological dislocation. So far as is known there was never any swelling or other sign to call attention to the hip-joint, and no pus formed, or, at any rate, no abscess was opened. Nevertheless, there is a dislocation that is easily made out, and the x-ray plate shows that the joint has been completely disorganized.

Such a condition may well be termed "quiet" infective arthritis owing to the absence of any definite occurrence to call attention to the condition. As in this case the hip is the joint most usually involved, possibly owing to its deep position, but other joints may in the same way become affected without attracting attention, especially in patients lying desperately ill from a blood infection. The knowledge of the possibility, as illustrated by this case, will no doubt help to emphasize the importance of keeping a watchful eye on the joints in all cases of acute infective illnesses.

ACUTE INTESTINAL OBSTRUCTION.

A SERIES OF 282 CASES.

BY

E. R. FLINT, F.R.C.S.

SURGICAL TUTOR AT THE GENERAL INFIRMARY, LIVERPOOL.

THE object of this paper is not to detail the frequency of the various kinds of acute obstruction, or to show the relative proportions in males and females and the ages at which they occur, etc. These points have all been worked out in papers by many authors. It is mainly to the subject of treatment my remarks will be directed.

The operative mortality of acute obstruction is generally held to be somewhere between 40 and 50 per cent. in a series of cases. There is no doubt this large death rate is attributable in no small degree to operation being performed on cases sent into hospital very late in the disease, but I hope to show that by making use of the results revealed by recent experimental work it is possible to reduce this mortality very materially.

This series of cases is 282 in number and a consecutive series upon which I have operated in a period of two years. They were taken as they came, without any attempt at selection as regards suitability for operative purposes, and are a very fair sample of the type received into any large hospital.

There is no doubt that there has been much improvement of recent years in the matter of early recognition of serious abdominal cases of all descriptions, but acute intestinal obstruction has still a very heavy mortality, which is due partly to delay and partly to the very vital character of the organs concerned.

The mortality in this series is 15.6 per cent. As will be seen from the table below I have included strangulated external herniae and acute obstruction from carcinoma. It is not usual, perhaps, to classify these with the ordinarily accepted cases of acute obstruction. Leaving these out of account, there were 70 cases, with a death rate of 28.5 per cent. This is still too great a mortality, but a considerable improvement.

Classification of Cases and Mortality.

	No of Cases.	Deaths.	
		No.	Per cent.
External herniae	170	18	10.5
Bands and adhesions	39	10	25.6
Intussusception	25	10	39.4
Carcinoma of intestine	42	6	14.5
Volvulus	2	0	
Internal hernia	1	0	
Thrombosis of mesenteric vessels	1	0	
By gall stone	1	0	

I included external herniae because the pathology is essentially the same as that of many cases of strangulation by band, and the carcinoma cases are included because they were admitted as emergencies, and in many of them the only diagnosis possible before operation was acute intestinal obstruction.

Let us consider first the experimental work, the application of which, I hold, is of the greatest importance in the treatment of acute ileus.

Wilkie¹ has shown that the contents of the intestine above an acute obstruction are very toxic and teeming with bacteria, and that the mucosa protects the organism against a toxæmia until it becomes seriously damaged by great distension, demonstrating the important selective and neutralizing function of the intestinal mucosa. The work of McLean and Andries² fully confirms this.

Further confirmation of the late absorption of the toxic contents of the intestine was established by Wilkie in a series of experiments on cats, in which he produced an acute obstruction and then injected into this obstructed part the toxic contents from the intestine of cats which had died of an acute obstruction. If toxic absorption had killed the first series, and the second started out with its obstructed intestine filled with the toxic material from the first series, symptoms of toxæmia should very quickly supervene; the results, however, were the same as in the first series. If, then, toxæmia is not responsible for the symptoms of acute ileus until a late stage, to what are the early symptoms due? Wilkie's experiments on cats show that early death in acute strangulation is mainly due to shock with its associated splanchnic paresis and depleted systemic circulation (internal loss of fluid); that peritonitis plays an important part only after some twenty-four hours, when the vitality of the mucosa has been considerably interfered with. Death in high intestinal obstruction—as opposed to strangulation—is due to shock also, but in this case the fluid is largely lost externally through excessive vomiting, as well as into the tissues, and in the absence of strangulation the vitality of the mucosa persists much longer. Death in low obstruction is much later in its occurrence, owing to reabsorption of much of the intestinal secretion poured out into the upper reaches of the intestine.

Among the effects of shock are a concentration of the blood and increased viscosity due to loss of plasma from an abnormal permeability of the capillaries. Severe pain, which causes an outpouring of adrenaline from the suprarenal glands, can produce these evidences of shock, as shown by Elliott, Cannon, and others. And it is not too much to suppose that the severe pain, probably peritoneal in origin, caused by acute obstruction of such vital parts as the intestines, is enough to bring about this outpouring of adrenaline and the production of shock. Later, the shock will be kept up by toxic absorption, for, as Dale and Landis³ have shown in their experiments with the poison histamine, shock may be produced, and this substance acts apparently in the same way as many products of protein digestion and bacterial activity.

In cats Wilkie has demonstrated the immense value of subcutaneous saline infusion. In obstruction of the distal part of the duodenum in a cat the animal vomits large quantities of bilious fluid, is very thirsty, and loses weight rapidly, dying usually within seven days of onset. If, however, the animal be given daily subcutaneous infusion in large quantities with 3 per cent. dextrose, not only will it show immediate improvement, but life will be prolonged for many days beyond that of a control animal.

Another point of much importance is brought out by Wilkie, and that is that toxic absorption from the intestine below an obstruction, after the relief of this, has been greatly exaggerated; indeed his experiments scarcely permit of its occurrence at all. The intense danger, however, of the least soiling of the peritoneum with this highly toxic material is forcibly emphasized. He concludes that peritonitis plays little part in the causation of death in simple acute obstruction until the late stages, unless accidental soiling occurs at operation. I shall revert to the practical surgical application of these experiments after considering those of another experimenter—namely, Crile.

Crile's⁴ work is mainly concerned with shock, and as shock is closely associated with the cause of death in acute ileus, his experimental work is quite pertinent. He has elaborated a very perfect technique for the prevention and lessening of the harmful effects of severe and prolonged stimulation. The principle of this association is the blocking off of the entry of the stimuli to the higher centres of the nervous system, both physical and psychological stimuli. This is accomplished by the free use of morphine, local anaesthesia, and gas and oxygen as a general anaesthetic. Morphine lessens the conductivity of the nerve paths, whereas strychnine, which is often given to patients suffering from shock, to "back them up," as it is said, increases conductivity, and so enables the noxious stimuli to get to the nervous system more easily. Morphine should only be given in the absence of cyanosis; this symptom, according to Crile, indicates a state of acidosis, and morphine impedes the efforts of the tissues to rectify it. Morphine should be given in repeated doses at half-hourly intervals until the respirations fall to 12 or under. The ideal method is, of course, to get the morphine in first, before the painful stimuli begin; naturally this is not possible in acute ileus, but even so the effect of the drug is to cut off much of the shock producing stimulation.

Local anaesthesia, when efficiently performed, cuts off all stimuli arising in the blocked area. The reason for using nitrous oxide is this: Crile found that this anaesthetic so protected the central nervous system that very few or none of the characteristic changes which are produced in the cells by excessive stimulation appear when stimulation is applied during the administration of this anaesthetic; whereas during ether or chloroform narcosis the same changes occur in the cells, and with nearly as great ease as when the patient is conscious of pain.

In my series of cases these principles were deliberately utilized. I did not, however, always use local anaesthesia, and open ether was the general anaesthetic always employed. Gas and oxygen has this practical objection: that many anaesthetists find much difficulty in obtaining a sufficient relaxation, and this is particularly impeding to the surgeon in such a condition as obstruction, where the distended intestines are often extremely difficult to control even under the most favourable disposition of affairs.

It is evident, therefore, that it is not in the best interests of the patient merely to operate at the earliest moment. Certainly, broadly speaking, the sooner the patient is brought to operation the better, but there is usually an interval between deciding to operate and the commencement of the actual operation—an interval of perhaps an hour or two at the least, during which measures should invariably be taken to assist the resources of the patient, both against his disease and against the additional shock of the approaching operation.

In addition to the usual measures of warmth, washing out the stomach, and so on, there are two of the first importance—namely, saline infusion and morphine.

First, with regard to saline infusion. This should be given at the rate of at least two pints an hour before operation, and continued during and after operation at about half this rate. Five per cent. glucose should be added, and it will usually have to be given subcutaneously. I think saline infusions are absorbed more quickly when given by the rectum, but in acute ileus they are not always well retained. It is common knowledge that in deep shock saline has a very transient effect; nevertheless, even then it produces temporary improvement in the patient's condition. The earlier it is given the better the effect. Dale and Laidlaw suggest the addition of calcium ions, as this drug has a specific action in reducing the permeability of the capillaries. I have tried calcium chloride in 0.05 per cent. strength, and have not been able to convince myself that it is any more efficacious than normal saline. I am not sure that whole blood would not be better, but, so far, I have not been able to satisfy myself that this is the case in acute obstructions.

The second measure to use is morphine. As soon as it has been decided to operate the sooner morphine is given the better. To an adult $\frac{1}{4}$ grain may be given at once, and repeated in doses of $\frac{1}{4}$ grain, or just over, every half-hour until the respirations fall to about 12. I usually give $\frac{1}{2}$ grain to quite young children with intussusception for example, and repeat it. Morphine should be continued after operation and the patient be allowed gradually to come out from its influence during the succeeding twenty-four hours.

Pituitary extract is another useful drug. It exerts a prolonged and general contraction of the circulatory system, and thereby diminishes the total capacity of this system, and mitigates the effect of deficient blood volume. After operation it may help to produce muscular contraction of the intestine. Eserine is another drug which may be used for this latter purpose.

For the last ten minutes of the operation the patients were made to breathe pure oxygen through an inhaler. This seemed to better their condition, and I am not sure it would not be a good thing to keep this up for some time after, in much the same way as is done for cases of gas poisoning and others.

As to the operation itself, the earlier in the case it is performed the simpler it will be, and in the more leisurely manner may it be done. As a rule, the cases are not seen at this desirable stage, and quick operating is usually required, and at times is absolutely essential; but rapid, inaccurate, and rough work is responsible for many deaths. Repeated indecisive handling of the same parts is to be avoided. Precision, with gentleness and the minimum of exposure, are the essentials for success. Plenty of warm and moist towels to cover intestine, which may unavoidably

prolapse, or be purposely turned out, and more than usual care to avoid soiling, are points which require particular attention.

The most useful incision is a right para-umbilical one, splitting the rectus muscle. In some cases a large intestine growth will be found, and colostomy or typhlotomy be required. The central incision is then used for the purposes of exploration only, and stitched up before the artificial anus is made through a separate opening. If the intestine be found viable nothing remains to be done but release it, either by freeing the adhesions, or, if the obstruction be by band, this will need dividing and ligaturing close to both its attachments.

It may be found that the line or lines of compression are anaemic, or even have cut through into the intestinal lumen, the rest of the gut being returnable with safety. In this case it is wiser to bury this area than attempt a resection. Any suturing which has to be done requires infinitely more care than is necessary in suturing under non-obstructive conditions. It is almost certain that the serous stitch occasionally penetrates into the lumen of the gut, and is not attended by disaster, but in obstructed and tightly distended intestines leakage occurs at such a point, with an inevitably fatal result.

Enterotomy, merely to drain the intestine at the time of operation, is never necessary, and is a very risky procedure.

It often happens that there is a sero-sanguineous fluid in the peritoneal cavity in cases of strangulation. This should be mopped out, and no drainage employed in the absence of offensive smell. This fluid may be present for forty-eight hours before it becomes infected. If there is even a faint faeculent odour about it a tube should be inserted into the pelvis through a stab wound. Any such smell means also that the intestinal wall is incompetent at some point, and would be an indication for not merely returning the intestine into the abdomen.

Whether the intestine is viable or not requires experience to determine in many cases. When the colour is a dirty grey or greenish-grey, or the brown of a dead leaf, and the gut feels like wet blotting-paper, it is quite certain that recovery is impossible; it is equally certain that it will recover when the colour is red, or even black, if there is any resistance to touch in the walls. It is in the intermediate stages that difficulty may arise. I think more reliance may be placed on the fingers than the sight in these cases. If the walls feel limp and offer no sensation of firmness to the fingers—it is, perhaps, too much to call it resistance—then it is not likely that recovery will occur. The mortality of all cases not requiring resection in this series was 9.3 per cent.—that is, 236 cases, with 22 deaths.

When it has been decided that resection, or anything more than merely freeing the intestine, is necessary, the utmost care should be expended in isolating the field with protective appliances. Gauze swabs wrung out in hot saline are carefully packed in all round, and over these, protecting them and the edges of the wound, are placed mackintoshes; these consist of a sheet of dental rubber stitched into a thin gauze covering. These serve two purposes—they prevent in a most efficient manner the entrance of septic material from the damaged intestine; and, secondly, they keep in the natural moisture and warmth much better than does a pervious material like gauze alone.

Having protected the field one proceeds to deal with the damaged gut. In most cases this will mean resection. After removing the necessary amount of intestine it is as well to empty some of the contents from the proximal segment by inserting Moynihan's tube. This makes suturing much easier. A lateral anastomosis is the best method of union to employ, because it is safer and there will be much difference in calibre between the two ends. Enterostomy should only be done in the very desperate cases. It is not always easy to know exactly where the opening is being made, and if high in the intestine the patients waste rapidly. Also it is necessary, as a rule, to do the second operation within a few days of the first, when the patients are not fit to endure much manipulation, and it is just these cases which are exceedingly difficult to deal with. Consequently the mortality is a very high one after the second operation. Nevertheless, some desperate cases have been now and again saved by this measure.

One more practical point, which I have found of great use, is the finding of the obstruction. Much needless exposure, and therefore much avoidable shock, is prevented by first examining the caecum and terminal ileum. Distension of the caecum, of course, means obstruction in the large intestine, and the condition can be dealt with as below. But if one finds a piece of collapsed ileum, this should be followed towards the stomach until the distended intestine is met. The examined part is returned as finished with. This method only requires about 2 in. of gut to be out of the abdomen at any one moment.

It should always be kept in mind that there may be more than one band causing obstruction; in my series there were two such cases.

In this series there were 46 cases which required resection; 11 of these were intussusceptions, with 9 deaths. This is in marked contrast with the reducible cases, of which there were 15 with 1 death. The youngest successful resection was in a girl just under 3 months old.⁵ The mortality of all resections was 45.4 per cent.

Of the cases in Group 2, 12 were the result of bands and adhesions due to the presence of tuberculous mesenteric glands, 9 to bands not of tuberculous origin, 4 to Meckel's diverticulum acting as a band, 1 to the appendix acting as a band, and 13 to adhesions resulting from previous operations—2 of these occurred during the first few days after appendicectomy with drainage. It is interesting to note that when adhesions caused the obstruction, this appeared to result from a rotatory effect given to the intestine rather than from kinking.

The volvulus cases were both of the caecum—one was merely reduced and fixed, the other required resection.

The internal hernia was through a hole in the mesentery, and whether of congenital origin or not was not determined, though there was no history of injury.

The case of thrombosis of the mesenteric vessels required resection of some 41 feet of small intestine, apparently about the lower jejunum, and was successfully accomplished.

In the gall-stone case the stone was impacted in the lower ileum, and was removed, the intestine being sutured.

Of the external hernia cases there were 170, with 18 deaths, a mortality of 10.5 per cent. Fifty were inguinal, with the strangulation at the external abdominal ring in at least 40—it was only found at the internal ring in 5; there were 3 deaths. Ninety-eight were femoral, with 11 deaths. Eighteen were umbilical, with 4 deaths.

Resection was performed only once in the inguinal cases, 18 times in the femoral, and 4 times in the umbilical.

It is interesting to note how much more serious to the vitality of the intestine is a femoral hernia, probably due to the much tighter ring.

Most of the femoral hernia cases were operated on from the abdomen through the outer part of the rectus sheath. It was necessary to free the sac from below, and Gimbernat's ligament was also usually divided from below. The peritoneum was efficiently protected, and first the gut reduced and dealt with from above, and later the sac was turned inside out into the abdominal wound. There is a distinct advantage in this method in two ways—first, it gives much more satisfactory access in case resection be necessary, and secondly, a radical cure is more easily effected, for the neck of the sac can be stitched up into the abdominal wound and the inner end of Poupart's ligament can be stitched to Cooper's ligament under direct observation on the upper side of the pubic arch. Also, if thought necessary, a piece of the rectus muscle can be carried across to Cooper's ligament, though I have never found that this was required. I have never seen a case recur after this method, though it is probably claiming too much for it to expect never to see a recurrence.

As regards the carcinomata cases, it usually happens that a positive diagnosis is only made after an exploration by a right para-umbilical incision. It is unfortunately true that most cases of carcinoma of the colon are only recognized either after giving rise to acute obstruction or on the discovery of a tumour. When the patient is desperately ill it is better to do typhlotomy at once, but when possible an exploration is advisable to ascertain the position of the growth and the feasibility of subsequent removal. If the growth is in the sigmoid and irremovable a colostomy should be done, but if removable, typhlotomy.

There is no doubt that the danger of sepsis at the second operation is thereby much reduced. A growth higher up in the colon requires either typhlotomy or, when in the descending colon or left half of the transverse colon, transverse colostomy may be done; if, however, there is a removable growth in these parts I believe it is always better to do typhlotomy.

Carcinoma of the rectum, of course, can be diagnosed before operation, and in any case requires a colostomy.

ABDOMINAL PAIN:

ITS MECHANISM AND CLINICAL SIGNIFICANCE.

BY

A. E. MAYLARD, B.S.LOND., F.R.F.P.S.GLASG.,
F.R.S.EDIN..

HONORARY CONSULTING SURGEON TO THE VICTORIA INFIRMARY,
GLASGOW.

POSSIBLY no symptom in the whole realm of disease is of greater interest and of wider distribution than that of pain. To the uninitiated it is often considered a mystery, more perhaps from its moral aspect than from its clinical. To those of us who regard it in the light of an indication that Nature is conveying information of considerable physiological and clinical importance in the elucidation of functional and pathological disorders, it becomes a subject of the greatest significance. As a study in itself, pain embraces an accurate knowledge of certain anatomical and physiological facts, as well as a comprehensive investigation into the morbid processes of disease. The subject is naturally a very wide one, and in the short hour at my disposal I can only deal with it in a very restricted way. My remarks, therefore, are to be limited to the discussion of pain as it is manifested in the abdomen.

For us, as clinicians dealing with the symptoms of disease, the most practical part of all these considerations about the nerve supply of the various parts of the body is that which concerns the ultimate distribution of the spinal nerves; for it is by means of these that we gain a great deal of our clinical information regarding the various seats of disease, and sometimes also the particular nature of the disease. It behoves us, therefore, to remember very accurately the final distribution of every nerve that leaves the brain and spinal cord to end in some part of the body. Take, as an example, the sixth thoracic intercostal nerve. In its course between the sixth and seventh ribs it gives off close to the spine its posterior primary branch, which is distributed to the skin between the lower angles of the scapulae; then, about the middle of the intercostal space, from before backwards, it gives off its lateral cutaneous branch, which ends in the skin on the side of the chest a little below the level of the lower end of the scapula; and, finally, the nerve ends in the sensory organs contained within the skin of the epigastric region at its upper part.

[Here the lecturer showed by means of diagrams the various anatomical connexions between the sympathetic nerve system, the spinal cord, the nerves, and the viscera.]

Clinical Significance of Pain.

Let us turn our attention to the practical application of the knowledge by which communications take place between the brain and spinal cord and the various parts of the body, and see how it works out in the diagnosis and treatment of disease. As a first clinical example we may take pain felt in the epigastrium, the side, and the inter-scapular region in the case of chronic gastric ulcer. The nerve supply of the stomach is, of course, by means of the two vagi and the sympathetic solar plexus, the latter being intimately connected with the coeliac plexus, which in its turn receives nerve branches from the subsidiary plexuses that are directly associated with the stomach. When, then, ulcer of the stomach causes pain to be felt in

* Abstract of a lecture delivered to the students of Queen Margaret College, University of Glasgow.

the parts before mentioned, the lines of communication between the seat of disease and the centres of pain are those that have already been anatomically traced; thus, from the great solar plexus, the large splanchnic nerves pass upwards to the sixth thoracic sympathetic ganglia, fibres from which pass onwards to the cells in the posterior cornua of that segment of the cord which also receives fibres from the sixth thoracic intercostal nerve. Now, inasmuch as these spinal nerves have at their terminals sensory organs capable of producing the impression of pain it follows that this pain will be experienced in those parts where these sensitive organs are located; and those in the case of the sixth intercostal nerve will be in the epigastrium, the side of the chest, and between the shoulder blades. Pain thus occurring, not at the actual seat of disease, but at some other place, often at a considerable distance, is called a "referred" pain. Nearly all pains felt in connexion with abdominal disease connected with the viscera are of this "referred" character.

To illustrate this further, let us take some other examples: those, for instance, connected with the presence of gall stones and those associated with the existence of calculi in the kidney. Here we have two organs closely related anatomically to each other, with many symptoms also much alike, but in which the acute colicky pains are widely different in their seats of distribution. To explain this divergence of two organs so closely related and so similarly affected, we have simply to refer to the anatomical distribution of the nerves respectively associated with each viscus in order to ascertain how the affected viscera cause the symptom to become manifested in a distant part of the body. In the case of gall stones, the first link in the chain is the hepatic sympathetic plexus. This plexus is, of course, connected with the coeliac plexus, itself intimately associated on the one side with the great solar plexus, and on the other side with the phrenic ganglion, which is situated in the diaphragm. It has already been shown in the case of the stomach how the solar plexus by its somatic connexions causes pain to be felt in the epigastrium. It is the connexion of the hepatic plexus with the phrenic ganglion situated in the diaphragm that explains the right shoulder pain; for this ganglion, through the medium of the phrenic nerve, is brought into relation with the fourth cervical nerve that distributes branches over the shoulder.

Another interesting example of "referred" pain is that connected with acute appendicitis. In this disease the initial seizure is frequently felt in the umbilical region before the pain settles down into the right inguinal region. The sequence of events is not difficult to follow. The inferior mesenteric plexus supplies the ileo-caecal section of the intestinal canal, and therefore the appendix also; but this plexus, through the medium of the aortic plexus, connects with the solar plexus, so that a communication is set up with the large splanchnic nerve. This nerve connects, through the corresponding sympathetic ganglia, with the fifth to the ninth or tenth thoracic intercostal nerves, whose final distribution is the epigastric and umbilical regions, where are the sensory end-organs that give rise to the feeling of pain. That pain is later felt directly in the right iliac region over the actual seat of disease is probably due to the inflammatory involvement of the parietal peritoneum, which is an extremely sensitive structure, and readily causes pain when overstimulated by any unnatural agency.

I am anxious now to present the picture in another form. In our practical clinical work we do not begin with a knowledge of the organ diseased and explain the presence of the pain; we do just the reverse. We investigate the nature and situation of the pain, and from these data seek to discover the disease. I am going, therefore, to ask you to examine a specific instance of a patient suffering from pain, say, in the epigastric region, and to seek with me to differentiate its clinical significance. It should be remembered, in the first place, that we are dealing with a "referred" pain, not with pain that is dependent on some local mischief in the abdominal parietes, but with that which is the result of influences transferred from some distant organ or tissue. Our first natural thought connected with pain in this region would be that it might be of gastric origin, but as there may exist no other symptoms suggestive of disease or functional derangement of the stomach, what other causes could give rise to it? I think that if you have followed

me in all that I have already indicated regarding the way in which the various nerve influences are conveyed you will readily understand how it is possible for certain sensitive cutaneous areas to be the focalizing seats of pain indicative of disease in more than one organ or tissue. This fact is very plainly demonstrated in the case of epigastric pain. You will remember how many abdominal viscera are associated through the medium of their respective sympathetic plexuses with the great central solar plexus, and how this plexus again, by means of the large splanchnics, is brought into connexion with the sixth and other intercostal nerves; so that, for instance, any acute disease of the pancreas—to mention only one viscus—would be as likely to cause pain in this region as an acute gastric disturbance.

What I wish more particularly to draw your attention to is the fact that not only can epigastric pain result from influences derived from diseased viscera, but that the involvement of any link in the chain between its two terminals—the cutaneous structures and the viscera—can equally evoke pain in this region. Before the splanchnic afferent nerves can excite the somatic afferent nerves both must more or less come into association with the cells of the posterior cornua. If, then, these cells become unduly excited by disease in the spinal cord, which directly involves them, a precisely similar result ensues as if they had been overstimulated by influences brought to them by the splanchnic nerves. This is what happens in patients suffering from *tuberculous dorsalis*, who frequently complain of acute seizures—crises—of epigastric pain. But, further, suppose the sixth intercostal nerve is involved in any part of its course between the spinal cord and its ultimate seats of distribution, pain will similarly occur in the epigastric region. This is precisely what happens in some cases of pleuropneumonia and in tuberculous caries of the spinal column. It is extraordinary how many mistakes have been made where epigastric pain has arisen from these causes. In the early stages of our abdominal work I fear that there were few surgeons who would not have had to confess to errors of judgement in this respect, more particularly in the cases of inflammation of the lungs and pleura.

I might take up other cutaneous areas where "referred" pain is felt, the cause for which could be attributed to more than one source. I think, however, that I have said enough to excite your interest, and indicate to you the important clinical fact that we must never stake our diagnosis on one solitary symptom however prominent and significant that symptom may be. Possibly you will be struck more forcibly with the value of adopting this method of clinical research in seeking to trace the cause of a "referred" pain if I instance a somewhat puzzling case that I recently encountered. It was a patient who had acute appendicitis, and in whom the most dominating symptom was a severe and continuous pain over the right shoulder. It led to the natural inference that the cause of the trouble might be gall stones. But the deciding factor in arriving at a correct diagnosis was the rigidity of the muscles in the right iliac and lumbar regions, and the pain produced on deep pressure in these parts. The abdomen was therefore opened as for appendicitis in the right iliac region. The diseased viscus was found lying upwards under the ascending colon. It was free, but from the existence of free turbid fluid in and around the region of the appendix there was evidently a certain amount of peritonitis. This I think is the probable explanation of the "referred" pain felt in the shoulder. The peritonitis in the region of the appendix extended to the liver and the under surface of the diaphragm; this caused an involvement of the phrenic ganglion, and as the phrenic nerve connects this ganglion with the fourth cervical spinal nerve, the pain over the shoulder is at once explained. The fact that the removal of the appendix and the subsidence of the peritonitis completely cured the pain sufficiently suggests that the explanation given was probably the correct one.

Variations in Manifestation.

It is interesting to consider the various conditions that affect both the nature of the pain produced, its extent, and its degree of severity. As clinical factors of diagnostic significance they are of considerable importance. As regards the nature of pain, we are almost entirely at a loss to explain why, for instance, a pain should be of a

"burning" character, "cutting," "stabbing," or "gnawing" like toothache. A pain of the intermittent "colicky" or "gripping" type does, however, admit of a more or less satisfactory explanation, for it indicates an unduly violent effort on the part of involuntary muscles to expel some foreign or excessively irritative material, or to overcome obstruction. We encounter this type of pain in chronic intestinal obstruction, and also in the presence of renal and biliary calculi. With this exception, however, the other characters of pain seem to be inexplicable; and from the fact that the same disease may cause different types of pain we are unable—at least at present—to attach much clinical importance to these varied manifestations.

When we come to consider pain from the point of view of degree or severity we are brought up against some very interesting problems. The first of these concerns the individual regarded as a collective organism. Some patients have a much more sensitive nervous system than others, so that what may be easily endured by one may be almost beyond toleration by another. These normal constitutional variations are always worthy of careful consideration. Then we have the effect of certain blood conditions which may have an augmentative action on the sensitiveness of the system to pain. In fever, for instance, the increased temperature may unduly excite those cells in the spinal cord or brain which are concerned in the production of pain; and these cells may also be similarly affected in certain anaemic conditions of the blood—possibly, from impoverishment, the result of deficient or defective nourishment, they are more susceptible to stimulation.

With regard to the distribution of pain, there are equally some very interesting problems to solve. To give an instance or two of what I particularly refer to: Why should pain in appendicitis sometimes be felt in the left iliac region? Why should stone in the kidney on one side give rise to pain on the other—a reno-renal reflex as it is termed? You will remember that, when discussing the causes of "referred" pain, I indicated how it was in all likelihood explained: that certain cells in the posterior cornua of the spinal cord, lying in close contact with other cells, when stimulated, transferred that stimulation to those other cells, and thereby caused an impression to be produced which accounted for the particular location of the pain. Now, these cells in the one cornua are connected by nerve filaments with similar cells in the other cornua; and if we assume that, for some unexplained reason, the cells in the opposite cornua are more sensitive to exciting influences than those on the side of the disease, we get the impression produced that the disease is on that particular side.

Let me instance a case that came under my observation many years ago—in the pre-x-ray days. The misfortune which followed the operation performed could not very well happen now when, by means of photography, we are so able to assure ourselves as to the existence or not of a stone. The patient referred to complained of pain in the right lumbar region, strongly suggestive of renal calculus. The kidney was cut down upon and explored, but no stone was found. The patient died four days after the operation from suppression of urine, and at the necropsy a stone was found in the left kidney.

It is but a further extension of the explanation that I have just given to understand how it is that pain may be widely diffused or distributed and not "referred" to any particular part or region. For if owing to undue excitability of all the cells in the spinal cornua more than those normally stimulated become involved, you can readily appreciate how much more extensively diffused must be the area of pain felt. Thus it sometimes happens that when these cells are in an unduly excitable condition, or when, perchance, the stimulus itself is of so acute a nature that it oversteps the limitations of even normal cells, the pain resulting from disease of an abdominal organ may not be limited to any particular part of the epigastric, umbilical, or hypogastric regions, but be more or less diffused over two or more of these regions.

I have not time to touch upon many other points which the study of abdominal pain presents, and this short hour has only permitted me to deal with the fringe of my subject. If I have done no more than to excite your interest I feel sure that that awakened interest will prove useful to you in the future pursuit of your profession.

THE PHYSIOLOGICAL COST OF MUSCULAR WORK.

BY

LEONARD HILL, M.B., F.R.S.,

AND

J. A. C. CAMPBELL.

IN the article published in this JOURNAL (May 7th, 1921, page 669) Waller and De Decker record results giving the physiological cost of muscular work of colliers, shoemakers and others as measured by the exhalation of CO₂. We are carrying out experiments of a similar nature with Dr. E. Schuster's modification of Martin's bicycle ergometer—doing 13,000 kg.m. of work per hour—using both the method employed by the above observers and the standard Douglas bag method, in which both the CO₂ output and oxygen use are measured, and the heat loss calculated therefrom, as recommended by Cathcart.¹ As the results we have obtained with these two methods rarely agree, we consider that the possibility of limitation of Waller and De Decker's method should be emphasized before deductions other than the broad difference between light and heavy work are drawn from their results. We consider that a source of error is the short duration—thirty seconds—of the period for obtaining the sample of expired air. We have found that the volume of CO₂ expired while at rest or at work varies greatly during consecutive half-minute periods (Table I), and also that the CO₂ exhalation per second obtained in a thirty-second sample is rarely similar to that obtained per second during a four-minute period (Table II).

	2nd	0.76	2.1	2nd	4.25	13.7
	3rd	1.10	4.1	3rd	4.03	12.6
April 4, 1921	1st	1.50	3.8	1st	4.49	13.1
	2nd	1.45	3.7	2nd	4.52	13.6
	3rd	1.24	3.3	3rd	4.60	13.8

* The heat loss in all tables centimetre per second. Cathcart
On April 4th J. A. C. had been mouthpiece.

TABLE II.—*Half-minute and Four-minute Samples.*
(No food taken. Subject C.P., accustomed to use of mouthpiece.)

Date		Half-minute Sample.		Four-minute Sample.	
		Heat Loss.	CO ₂ (c.cm. per sec.).	Heat Loss.	CO ₂ (c.cm. per sec.).
April 25, 1921	After 2 hours' work on ergometer	5.8	17.7	4.6	12.7
	After 3 hours' work on ergometer	6.3	19.2	—	11.0
	After 4 hours' work on ergometer	5.4	16.4	4.2	11.2
May 4, 1921	After 2 hours' work on ergometer	3.3	8.3	5.1	13.6
	After 4 hours' work on ergometer	4.8	12.7	4.9	13.2

Another factor on which these observers do not apparently place sufficient emphasis is the influence of food. Benedict and Carpenter have shown that the ingestion of all kinds of food in any amount results in an increment of metabolism.² We have obtained similar results. We think that there is a danger of a reader misinterpreting the charts and tables as presented by Waller and De Decker. In nearly all their cases the cost per hour of "practically maximal and constant" work appears to increase as the day proceeds. Johansson's curves of diurnal temperature

and CO₂ output of a normal individual living a normal life vary together. This, we suggest, is due to the influence of food, and that if this be excluded the CO₂ cost per hour of this constant work remains the same at any period.³ Benedict and Cathcart's well-known experiments on a trained bicyclist in the post-absorptive condition, show clearly that severe constant work requires the same amount of CO₂ exhalation per second at the end of three hours of work as during the first hour.⁴ Using a bicycle ergometer and four-minute samples of expired air, we have obtained similar results (Table II): It is only after taking food (Tables III and IV) that our subjects show a rise of CO₂ exhalation similar to the increase shown in Waller and De Decker's charts.

TABLE III.—Showing Effect of Food whilst Resting.
(Subject C.P., resting. Ten-minute samples of expired air.)

Date.		Heat Loss.	CO ₂ (c.cm. per sec.).
April 20, 1921	One hour after food ...	1.13	3.2
March 30 "	" " " " ...	1.16	3.0
April 20, 1921	Two hours after food ...	1.43	3.7
March 30 "	" " " " ...	1.47	4.0

TABLE IV.—Showing Effect of Food whilst at Work.
(Subjects C.P. and L.H., working on ergometer. Four-minute samples of expired air.)

	Heat Loss.			CO ₂ (c.cm. per sec.).		
	L.H.	C.P.	C.P.	L.H.	C.P.	C.P.
Two hours before food	3.3	4.9	4.23	12.7	12.3	11.8
One hour before food	3.5	4.8	3.88	11.9	12.0	11.1
Food taken.						
One hour after food ...	3.9	4.2	4.9	13.1	11.5	12.6
Two hours after food	4.2	5.1	4.86	14.9	14.3	14.7

It is well known that a fatigued or uncomfortable subject carries out a given amount of work at a greater cost than when normal, but it does not seem reasonable that the colliers and shoemakers under consideration are so unskilled and of such poor calibre as to show signs of fatigue after a couple of hours' constant work, when this work is of the degree specified.

COMPARATIVE SYSTOLIC BLOOD-PRESSURE READINGS IN THE ARM AND LEG IN AORTIC INCOMPETENCE.

BY

O. K. WILLIAMSON, M.D. CANTAB., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE ELECT, UNIVERSITY COLLEGE, JOHANNESBURG;
 PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES
 OF THE CHEST; LATE ASSISTANT PHYSICIAN TO THE
 WESTMINSTER HOSPITAL.

THE higher systolic reading by the blood-pressure instrument in the leg compared to that in the arm, when both are at the level of the heart, appears to have been so generally accepted as a characteristic and even diagnostic sign in aortic incompetence that it would seem to serve a useful purpose briefly to review the subject, so as to consider whether or not this conclusion is a sound one, and, if not, what are the fallacies which underlie it.

Leonard Hill, with the co-operation of Martin Flack and W. Holtzmann,¹ first made the observation that in all cases of aortic regurgitation there is a marked difference between the reading of the systolic arterial pressure in the arm and in the leg, that in the leg being the higher, the observation being taken in recumbency. These observers further state that "when such patients are lying quiet in bed this difference is a diagnostic sign of aortic regurgitation." They found that the difference of pressure is not abolished by the method of oscillating the pressure up and down near the obliteration of the pulse. The explanation which they give of the difference is that the "big systolic waves are conducted better

down the leg arteries, these being slightly thicker and more contracted and rigid." In a later paper Hill and Rowlands² brought forward additional cases illustrating the same phenomenon. H. A. Hare came to similar conclusions to those of Hill.³ H. D. Rolleston⁴ confirmed the observation, and among other conclusions found that the difference between the maximum systolic blood pressure in the arm and leg was "marked in uncomplicated and compensated" but "is much less marked in aortic regurgitation when the compensation is failing, and in cases of combined aortic regurgitation and mitral disease"; further, that "in recent aortic regurgitation before compensation is established the difference is slight or may be absent." J. R. Murray⁵ published records showing similar differences. J. Heitz⁶ recorded observations on 51 cases concerning this phenomenon, and whilst finding it in the majority of cases, disagrees with Hill as to its constancy. He, moreover, draws attention to the important fact that the difference is to be found in other classes of cases. He says: "L'élévation de pression dans les artères tibiales peut être constatée chez la plupart des sujets atteints d'insuffisance aortique" . . . but "elle peut manquer dans un certain nombre de cas." Again: "L'élévation de la pression systolique aux membres inférieurs peut se constater avec une certaine fréquence chez des sujets hypertendus et non atteints d'insuffisance aortique." He has also found it in abdominal aortitis. He concludes that the sign "ne présente donc pas de valeur diagnostique absolue."

Such a difference of pressure readings may certainly occur in other conditions than aortic incompetence. Thus I have observed it in high-pressure cases associated with arterio-sclerosis,⁷ and, according to Clifford Allbutt, this observation was first made by Volkmann.⁸ Further, MacWilliam has found the same difference in some patients with sclerotic arteries.

The conclusions drawn from my own observations are as follows:

1. Although higher systolic readings in the leg than in the arm appear to occur in the majority of cases of aortic incompetence, there is a large minority in which they do not obtain.

2. There is no evidence that such cases, when they do exist, are the result of the actual aortic incompetence rather than of the commonly associated conditions of hypertonic contraction or hypertrophy of the muscular coat, with or without accompanying sclerotic changes, conditions which also occur independently of aortic incompetence.

3. In support of the arterial explanation of such differences is the fact that the large majority of cases of the series in which the arteries were thickened showed the difference, being a much larger proportion than obtained in the total number of cases of the series (all of which had aortic incompetence); and further, that in the adult cases of aortic incompetence, nearly all of which had thick arteries, the phenomenon was more than twice as common as in the children, in none of whom were the arteries thickened.

4. If due to the aortic incompetence it would seem reasonable to suppose that the difference of reading should show some relationship to the degree of incompetence, which for practical purposes may be considered as measured by the pulse pressure. No parallelism, however, exists between these arm-leg differences and the corresponding degrees of pulse pressure.

5. In the few cases in which this was tried, in the majority the difference of pressure was abolished by repeated recompression, a fact decidedly in favour of the arterial explanation. (In cases of a higher leg reading than that in the arm in arterial disease it has been frequently found that the difference is abolished by such recompression.)

Method of Observation and Apparatus.

This paper being based on observations which were spread over many years, different instruments were used, but these were one or other of the modifications of the Riva-Rocci method—namely, Stanton's instrument, Oliver's compressed air haemomanometer, Martin's instrument, and that of French.

The armlets used were at least 12 cm. breadth, except in a few of the children, in whom an armlet of 10 cm. was used for the arm observations. When not otherwise stated, the armlet for the lower extremity was placed on the calf. In the few cases in which the thigh was used for compression a specially broad armlet (18 cm. broad) was used. All readings were taken on reducing the pressure after obliteration of the pulse. In other words stated, the tactile method was the one adopted. In the readings by this method the radial artery was used for the upper extremity, the dorsalis pedis or posterior tibial for the

Cases.

	Sex.	Age.	Diagnosis.	Arm Reading	Leg Reading	Difference.	Pulse Pressure.	History.	Remarks—Arteries, Pulse, etc.
Adults.				mm.	mm.	mm.

* Not made synchronously.
recompression.† Indicates that the difference was abolished by recompression.
‡ Method of maximum oscillation for diastolic

lower. Dr. George Oliver's auditory tambour attached to a binaural stethoscope was used for the auditory readings. The tambour for the arm readings was placed at the bend of the elbow, and for those on the lower extremity at the popliteal space.

In the auditory readings the point of appearance of the audible throb was taken as the systolic reading, and unless otherwise stated the point at which the loud note becomes suddenly dull before the diastolic reading. In a few cases a T-shaped tube with both armlets. Observations of any case on different lines were made on different days. The patients were at rest in the recumbent position, and the results are recorded in millimetres of mercury.

Details.

This paper is based on observations of 24 cases of undoubted and, indeed, well marked aortic incompetence. In 14 of these a difference obtained in the arm and leg readings. In the 10 remaining cases there was either a higher arm than leg reading or there was no difference in favour of the leg reading. Two of the cases which did not show the difference had temperatures of 100° F. or nearly 100° F. at the time of examination. Rolleston,⁴ in his observations, found that in two cases temperatures of 101.4° F. and 100.4° F. respectively caused the difference to diminish greatly or to disappear. It is possible, therefore, that the slight degree of fever may have explained the absence of the difference in my two cases, so that I have thought it well to exclude these two cases from the list. This leaves 22 cases to be considered, of which 14 were adults and 8 children of from 15 years downwards. Of these 22 cases, 14 showed the difference, leaving 8 in which the sign did not obtain.

It is to be noted that 10 out of the 14 cases showing the difference had thick arteries (all except Nos. 8, 17, 21, and 23), or of all the 13 cases of the series having thick arteries 10, or all but 3 (Nos. 5, 13, and 14), showed the difference, a much larger proportion than that which obtained in the total number of cases (14 out of 22) all of which had, of course, aortic incompetence. Further, in the 14 adult cases 11 showed the difference, whereas by contrast it was observed only in 3 of the 8 children, in none of whom were any arterial changes found. These two points suggest very strongly the arterial origin of the phenomenon.

In regard to the relationship of the degree of pulse pressure to the arm-leg difference, there was no correspondence between the two. Taking the 6 highest pulse pressures, in 4 of them, Nos. 2, 3, 11, and 16, there was a marked difference, whilst, on the other hand, in the 2 others, Nos. 10 and 14, no appreciable difference was found. In 3 out of 5 cases in which it was tried, the difference of pressure was abolished by repeated recompression, which again is as we have seen in favour of the arterial explanation, and is at variance with Hill's finding aortic regurgitation.

It will be seen, if my results be compared with those of the various writers on this subject that they are similar to those of Heitz, but differ from those of the others, and it may be pointed out that Heitz's conclusions appear to be based, to judge from the published records, upon a considerably larger number of cases than those of the other observers.

Whilst of course I freely acknowledge that the limited number of cases upon which the present paper is based is insufficient to form the basis of general dogmatism, it is certainly quite sufficient to show that the phenomenon is nothing like a constant sign of aortic regurgitation. Finally, I would submit with some insistence that future observations should include in each case a note upon the condition of the arteries, an omission as to which has deprived past records of much of their value.

An Address

ON

ELEMENTARY PSYCHOLOGY IN GENERAL HOSPITAL TEACHING.

DELIVERED BEFORE THE ULSTER MEDICAL SOCIETY,
MARCH, 1921.

BY

WILLIAM CALWELL, M.D.,

PHYSICIAN, ROYAL VICTORIA HOSPITAL, BELFAST; MEDICAL OFFICER
IN CHARGE, CRAIGAVON HOSPITAL FOR NEURASTHENIC PENSIONERS,
BELFAST.

In August, 1920, I was instructed to examine a woman aged between 60 and 70, and report on her mental and general condition; she had had a stroke in 1912 and another two years later. She was bedridden. Both arms and legs were strongly flexed, the knees nearly touching the hips, the heels the hips, and the arms were crossed over the abdomen; she had no control over bowel or bladder; her articulation was very defective, resembling an exaggerated mumbling lip; orientation for time and space was hopelessly poor; she said she was 43, and that it was the year 1909; her memory was quite unreliable, her ideas extremely limited; she knew nothing about her affairs except that she got a certain sum a week from a deceased sister, and had been robbed of her furniture, and in making these statements she exhibited tearful but short-lived emotion.

I had no difficulty in making a report. In a subsequent letter I was asked whether I could give an opinion as to the time during which this patient had been incapable of managing her affairs, and whether there was any ground for forming an opinion as to what the mental capacity of the patient was likely to be after the seizure in 1912.

In trying to answer these questions I realized that my knowledge was very limited. It could be put into two statements: (1) After a stroke there is mental weakness, which may be of so slight a degree as to be unnoticed, or may amount to well marked secondary dementia, where the patient has returned to second babyhood; and (2) that there is a question how far aphasia meant intellectual incompetence. I answered that it was impossible to form a reliable opinion.

So I turned to our textbooks and to what medical literature I had time to consult. Some simply mentioned the question of examination of the mental condition of our patients, some gave a rough outline, a few lay emphasis on the "cerebral" features of arterio-sclerosis, by which I presume they meant "mental" or "psychic" features. This is the "arteriopathic dementia" of the alienist. It is interesting and instructive to note how even some of our best textbooks do not refer, or refer in an inadequate manner, to the difference between cerebral physiology and psychology. The textbooks on mental diseases are not included in this statement. Many of our manuals of medicine and monographs on the diseases of the nervous system consider elaborately the questions of cerebral pathology and of aphasia; to illustrate the latter subject the pages abound with diagrams which, rather unfortunately, recall from our unconscious memory the forty-seventh proposition of the first book of Euclid, and we are apt to associate with these diagrams the same childlike faith in the definiteness of proof and of absolute reliability that we learned in our boyhood to associate with the famous right-angled triangle; normal or morbid psychology is not touched upon.

Charcot, in his classical clinical lectures, takes up a very interesting attitude: the study of cerebral haemorrhage, he says, forms an introduction to the study of diseases of the encephalon. The sudden tearing of the tissue realizes in some degree the simplicity sought in experiments on animals, but he omits the mental condition. His further lectures were unpublished.

Our later textbooks and manuals on insanity do supply the want; whether in an altogether satisfactory manner or not is a legitimate subject of debate, but the effect of this separation is that the student and most medical men do not attempt to make even an elementary psychological examination of a patient, unless this patient is actually insane, and then only so far as to ascertain whether insanity exists or not. But a patient's mentation is a function of his brain; this function is continually being carried on; it is a function—not perhaps from a vital point of view, but certainly from a social point of view—which is incontestably the most important, and it should not be relegated to an odd half-dozen of lines.

Cerebral physiology is yet very incomplete, and so we should teach the elements of psychology to the student as part of the clinical examination of the most important function. At present it is left to the native wit of the doctor to size the mentality of a patient. Should we not train him in scientific methods? Would we give up our scientific and regular, orderly, means of physical examination because the native wit of Hippocrates enabled him to do so much? Let us rather correlate cerebral physiology and psychology to make as complete an examination of the functioning of the nervous system as our present knowledge allows, and obtain practical aid in the examination of our patients.

An examination of some of our excellent manuals on clinical examination and case-taking showed the same deficiency; the reflex movements of the big toe were strongly in evidence, but the powers of memory, of ideation, the depth of emotion, the occurrence and kind of dreams, and the bias of mind, the powers of expression, of calculation, were passed by unnoticed or barely noticed; Hutchison and Rainy in their *Clinical Methods* give a page on which is printed a special scheme for cases presenting mental symptoms drawn up by Henry Head for use in the wards of a general hospital. A student, however, is told in other places to practise examination on healthy lungs, hearts, urine, etc. Why should he not practise a little normal psychology, and so be better fitted to examine and recognize psychical abnormalities when they present themselves?

A student should have a certain amount of both normal and morbid psychological training before going to the asylum; he will be able to benefit by his training in that

institution; and, in his final undergraduate year and ensuing years of practice, he will be less apt to confuse psycho-neurosis with malingering, congenital defect or bodily disease, and so be enabled to give the proper and right treatment.

A revolution is taking place in this subject of psychology; it may be said to have begun with Freud of Vienna roughly at the commencement of this century. Freud was a physician and was led to his theories by the study of mental affections, but his theories concern a universal problem of psychology. It would be impossible even to attempt a brief explanation of Freud's "unconscious mind," "suppression," "censorship," "conflict," "psycho-analysis," "interpretation of dreams," etc. We should be led into an arid discussion of priorities and interpretations, but undoubtedly much merit and noteworthiness should be attached to his mechanism and the nature of his "mental conflict." Side by side with this psychological change is the great advance in cerebral physiology due to the work of Henry Head and his school in London. Thirdly, we have the enlightened and progressive study of the psycho-neuroses during the war and afterwards. And, lastly, we have the endeavour to correlate all three, as will be seen in the book, *Instinct and the Unconscious*, lately published by Rivers of Cambridge; he tries to show the various aspects of the psycho-neuroses as biological reactions. I shall make no attempt to explain the changes and advances in psychological theories, with the one exception of emphasizing the importance of instincts. The recognition of the nature, number, and power or influence of instincts has perhaps been the greatest change and advance; these instincts have been examined with the greatest care and exactitude, and have been defined with the utmost circumspection. Freud insists on the impulsive, demonic, illogical nature of much of human thought and the very partial and inadequate way in which consciousness reflects or represents the workings of these impulsive forces, which seem to be the driving power of life. Others have taken up the question, have enlarged the boundaries, and have built an edifice on a surer, steadier, and broader base.

Now let us consider for a moment the later cerebral physiology. Head showed that two forms of sensation—epicritic and protopathic—were present in sensory nerves: in the healing of a cut sensory nerve the protopathic sense returned long before the epicritic; the protopathic is concerned with somewhat painful or pleasurable sensations of heat or cold; it is vague and diffuse: it is conducted by the spinothalamic tract to the optic thalamus. The epicritic is much more discriminating: it is exact, differentiates, and the fibres travel by a separate tract to the cerebral cortex. The optic thalamus is the old brain. The neothalamus or cortex is later; it increases in size as we rise in the stages of evolution; it is with the cortex that the epicritic is connected. There are instincts of the protopathic type, and, as summed up by Rivers, they have the "all-or-none" principle in reaction:—

1. There is an absence of discrimination, of appreciation, or of gradation of response:
2. They have the character of reacting to conditions with all energy available:
3. And the character of the responses is immediate and uncontrolled.

These characters all hold good in large measure of the activity of the optic thalamus, the essential nucleus which Head and Gordon Holmes have shown to be the central representation of the protopathic aspect of peripheral sensibility and the essential basis of emotional reaction. The mad flight for safety of an animal is of this type; the instinct reaction for self-preservation is immediate, uncontrolled, with all energy available, and without discrimination; it is a panic. We need but to keep our eyes and ears open in everyday life to recognize examples; books of travel and the better class novel abound in them.

Or the opposite: The mad rush down all opposition, regardless of type. The chance of success in bo and completeness. In the better class of man we have an instinct reaction of self-preservation in what Rivers calls the "manipulative activity" reaction; the man at once instinctively becomes cool, quick-witted, without sense of fear or danger; he gets wounded and he feels no pain; each highly complex difficulty is met with dis-

criminating quickness of thought: this is a cortical or epicritic instinct reaction for self-preservation, and its success depends on the purity of its cortical nature. If a man "loses his head"—that is, if the epicritic nature of the instinct reaction wanes and the protopathic type interferes—his risks are quadrupled; he has the blind rage of the optic thalamus without its suddenness and full energy.

A good example of the contrast between the two is found in George Eliot's *Romola* (Chapter XXXIV) in the conflict between Tito, young, well nourished, selfish, and with a cool scheming brain, and Baldassarre, old, exhausted by exposure, privations, disease, with fast failing mental powers; the sudden impetuous leap of the latter and his secondary collapse correspond very closely with Rivers's description. *Romola's* interview with Savonarola in Chapter LIX is a fine instance of a good educated brain in a noble character acting under the strongest conflict and emotion, but always held in control: a weak cortex and weak nature would have gone into hysterics.

It is not difficult to see the resemblance between a protopathic reaction and a sudden outburst of an hysterical fit, or of mania, and a resemblance also to those cases where soldiers have suddenly taken to flight even into open danger.

Again we are not allowed by the public press just at present to forget that an animal may try to escape by sudden immobility or "slamming dead"; it can be rolled over, touched, and yet not exhibit the faintest movement; it is apparently without feeling; the paralysis, anaesthesia, mutism of hysteria may have the same origin.

In this way Rivers endeavours to correlate the psychology, the latest cerebral physiology, and the psycho-neuroses; the instincts of the animal of the optic thalamic type become modified in those animals whose cortex has increased in size and complexity; in man, under the stress of war or civil danger, functional diseases in their manifestations hark back to his optic thalamic ancestor.

In passing, I may remark that the war has done two things. Freud made the sex instinct the central and most important factor; he enlarged the use of the word "sexual" to a perfectly absurd extent, and broke through the plain use of words and of facts. The older psychologists were jealous of his innovations and held up to scorn, contempt, and ridicule Freud and his sex theories. The first iconoclastic action of the war was to knock to pieces the supremacy of his sex instinct; the second was to confirm the truth of his mechanism of the unconscious, suppression, psycho-analysis, sublimation, projection, etc. Comparatively few of the neurasthenic soldiers showed any predominant sex instinct; they led the ordinary sex life and never worried about it, except when they got some venereal disease, but the vast majority showed "danger"—that is, "self-preservation and herd instincts," "suppression," "conflicts"; they were treated on these lines and cured; so that Freud's mechanism was established, but his "sex instinct" theory, which might be more in accordance with fact in the highly artificial and effete civil life of Vienna, had to come down from its pinnacle and take its place with the two other main classes of instincts—namely, that of "self-preservation" and that of the "herd."

Again, there has been an enormous increase of public interest in psychology; lay practitioners in psycho-analysis are already beginning to swarm in London; the machinations of many, I am afraid, make for evil, and pander to the erotic vacuity of fashionable life. These charlatans will spread to provincial towns, and will soon be with us, and be adopted by the neurotic cranks of the district. Books are published as scientific treatises, whose illustrations and stories would delight the heart of the prurient pervert; but the higher class papers and reviews have also taken it up in a more legitimate manner.

A book on the psychology of employment, published recently in America, shows how the Americans are open to receive new ideas and improve their methods, and are not above taking lessons from any form of study; it deals with intellectual capacity generally, and emphasizes the two varieties: (1) General intelligence—capacity to benefit by experience and error; (2) specificability.

A third reason why the profession should not be ignorant of the subject is the immediate need for the treatment of the large number of war "neurasthenics," and the still larger number—proportionately increasing as the true

"shell shock" gets well—of the degenerate, work-shy, malingering borderline case, who did no work before the war, as little as possible during the war, and do not intend to work after the war. The Ministry of Pensions has taken the responsibility of these men, and it is our duty to educate ourselves and the public as to how to deal with them; they do much harm to our wounded and war invalids. The war found us well prepared as regards the prevention of infection, moderately prepared as regards the treatment of wounds, but in hopeless ignorance as regards the prevention and treatment of psycho-neuroses. We tolerated before the war in a supercilious manner some practitioners who specialized in this class of patient; a few—but still too many—of these were cranks themselves or quacks who battered on credulity and gave the bad name; but we ourselves were ignorant; we were guided by no scientific principles. The older surgeon looked with contempt on the bonesetter; he has now systematized the knowledge and experience of the bonesetter, and benefited the patient; the analogy is not too strained.

My object is to advocate the introduction of a simple elementary study of psychology, normal and pathological, into the wards of a general hospital, in order to formulate and systematize the instruction that is already given in a somewhat spasmodic and irregular manner; to train students and prepare them so that they will be able to benefit more fully by their attendance in the asylum, and be ready to take up this aspect of their professional life—the examination of a patient for responsibility of his actions, for testamentary capacity, and for the hundred small incidents that occur in our daily professional life, and the treatment of the minor mental ailments that form such a large part of general practice.

OBSTRUCTION BY A BAND IN A LARGE SCROTAL HERNIA.

BY

PHILIP TURNER, M.S., F.R.C.S.,

ASSISTANT SURGEON, GUY'S HOSPITAL.

INTESTINAL obstruction in a hernia, from causes other than constriction of the contents at the neck of the sac, is not of great rarity—I have heard of two such instances in the past year—but the following case presents features of unusual interest:

In September, 1919, I was asked by Dr. J. Thorpe Reckitt to see a case, apparently of strangulated inguinal hernia. The patient was a man, aged 69 years, who had a left inguinal hernia of remarkable size; its maximum length was about twelve inches and its circumference about eighteen inches while the patient was lying down in bed. The hernia had been present for forty years, and for many years—for how many the patient was unable to say—it had been irreducible and of its present size. No truss had ever been worn, but, in spite of its magnitude, the hernia seemed to have caused him singularly little inconvenience. He was able to lead an active life and attend to his business right up to the present illness. Some few years ago the swelling had been tapped by a medical man, presumably under the impression that the scrotal swelling was a hydrocele. No fluid was drawn off, but the patient was unable to say whether anything was injected into the sac.

His illness, which may be said to have started three days before I saw him, commenced with pain and tenderness in the hernia, followed by absolute constipation, neither faeces or flatus being passed. The symptoms at first were apparently not severe, so that he did not send for Dr. Reckitt until the third day, when the pain had extended to the lower part of the abdomen and he had commenced to vomit. When seen during the evening of that day his condition was very grave; the vomiting had persisted and he was then bringing up small quantities of foul brown fluid at frequent intervals. The pulse was not very rapid, being 100 per minute, but was of small volume; the tongue was furred but moist and the eyes were decidedly sunken. The lower part of the abdomen was tender and rigid, but, owing to the presence of much fatty tissue it was not possible to say if there was any distension. It was considered that the hernia was strangulated, with probably gangrene of some of the

contents. As it was thought that the patient's life might possibly be saved by relieving the obstruction and tying in a Paul's tube it was decided to operate.

Operation.

An anaesthetic was given and the sac exposed and opened in the usual way. The contents were chiefly small intestine, with a portion of the omentum and a small amount of foul blood-stained fluid. The neck of the sac was very large, and there was no difficulty in passing two fingers through it into the peritoneal cavity; the intestine showed no evidence of constriction, and it became certain that we were not dealing with an ordinary case of strangulated hernia. The omentum was ligatured and excised to allow of investigation of the bowel. It was estimated that about half the total length of small intestine was present in the sac; it was but slightly distended and the serous surface was hyperaemic. At the lower part of the sac a coil about 12 in. in length was found to be black and gangrenous. This was caused by a well-defined, rounded, fibrous band attached at each end to the mesentery, crossing and constricting both the proximal and distal ends of the coil, but having no attachment to the intestine. The gangrenous portion of the gut was sharply defined by the line of constriction, which was very tight, and, in addition, the whole of the affected coil was twisted through an angle of about 180 degrees. The band was situated at least 6 in. below the level of the external abdominal ring, and there was certainly no obstruction at the latter situation. The patient's condition was too bad to allow of a resection, so that, after the band had been divided, the gangrenous coil was drawn into the wound, incised, and Paul's tubes were tied in. The upper three-fourths of the wound were then closed and the patient returned to bed. However, he did not rally, and died in about three hours.

The nature of the band which caused the obstruction is doubtful. It was a definite, rounded, cord-like structure, attached at each end to the mesentery, but as it had no attachment to the intestine it can scarcely have been derived from a Meckel's diverticulum, though the gangrenous portion of intestine was probably ileum. It certainly had no connexion with the inguinal canal or the external abdominal ring, and there was nothing to suggest that it was derived from the omentum, which was not adherent to either the gut or the sac wall. No other bands or adhesions were noticed, and, indeed, I think that the reason that the hernia was irreducible was on account of its size and long duration, so that the capacity of the abdominal cavity was insufficient to accommodate its contents; at any rate there was hindrance to reduction at the neck of the sac, and no adhesion between the sac wall and contents.

One cannot help thinking that the band may have been inflammatory in origin, and that it may have followed upon the tapping which had been performed some years before. When I saw the patient there was no suspicion of a hydrocele, and at the operation there was only a small amount of fluid in the sac. Under these circumstances it is quite possible that the trocar and cannula may have inflicted some injury upon the mesentery, and that, as the result of the inflammation thus set up, the band was formed. In support of this view it may be pointed out that the situation of the band was about the level which would be selected for the introduction of the trocar and cannula in tapping a hydrocele. Whatever the cause of the band may have been, it is certainly a very unusual occurrence for a portion of the contents of a hernia to be obstructed in this way.

THE RADICAL CURE OF VARICOCELE.

BY

SIR JOHN O'CONOR, K.B.E., M.A., M.D.,

SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AIRES.

SOME six years ago I called attention to a simple and exact method of excising the eight or ten varicose spermatic veins (the pampiniform plexus) which are suspended, in loose areolar tissue, mostly in front of the vas deferens. It is essential to punctuate the fact that surgical intervention must be exclusively confined to removal of this bundle of veins, otherwise disastrous consequences are certain to ensue—for example, gangrene or atrophy of testis. I have seen many examples of the latter, and recently a very painful instance of the former—a gentleman who, just before embarking for Buenos Aires, was operated on by a well known English surgeon; on his arrival here he was suffering from marked toxæmia and a foul septic scrotum. I had to remove a gangrenous

testicle and found the cord itself tightly constricted in the ligature.

I cannot help thinking that operative textbooks are largely responsible for these mishaps by recommending procedures possessing needless magnification of perspective which often results in anatomical obfuscation—too much exposure and too much dissection frequently produce too much surgery. The essence of the thing is first to realize that the pampiniform plexus is situated anteriorly to the other structures of the cord, and then, before making the incision, to take care to secure it in that position—always remembering that the object is to remove a superficial bunch of varicose veins endowed with a definite topographical site, which may be easily confused by over dissection and unnecessary manipulation of the part.

The operation which I have employed for some years past is as follows:

1. This clump of varicose veins is seized horizontally between the left thumb and left index finger. A pause is made, to be certain that the cord lies free and well posterior to the gripping fingers. This is verified by palpation with the right thumb and right index finger, and I generally demonstrate the position of the cord to some onlooker by rolling it close under the skin for inspection.

2. A two-inch incision is then made over the gripped projection; with a few horizontal strokes of the knife the infundibular form fascia is divided, the offending plexus pops into the wound, and with a few more touches it is completely exposed through the whole length of incision.

3. These veins are then caught in mass by an artery forceps, which is handed to an assistant who pulls it vertically upwards so as to bring the underlying connective tissue into view.

4. A stab of the scalpel makes an opening through this tissue sufficient for the introduction of the right index finger; this done, the left hand grip is released, and the left index finger is instantly inserted alongside of the right one beneath the bundle of veins.

5. The pampiniform plexus is now freely separated from its bed by the two fingers (one working up and the other down) and as many inches as may be considered necessary are easily and rapidly isolated.

6. A catgut ligature is applied above and below, the intervening segment (usually 2 to 4 in.) of plexus is excised, the ends of ligatures are then tied so as to approximate stumps and to elevate scrotum, and the skin wound is united by a few catgut stitches leaving room at the upper and lower angles for the passage of a slender wisp of silkworm gut—a precautionary hæmorrhagic drain which I employ in all scrotal wounds.

The facility with which this little operation may be done can be estimated by the time occupied in its performance—one to three minutes. The results warrant its commendation to others.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

LIGATIONS OF THE LEFT SUBCLAVIAN ARTERY.

IN THE *JOURNAL* of April 16th, under the above heading, the possibility is suggested that some surgeons may have performed this operation without having recorded the fact in print. That this supposition is correct in at least one instance is borne out by the following case on which I operated during the summer of 1918 in France. No doubt other surgeons during the great war had somewhat similar cases.

A soldier was received at a base hospital with the diagnosis of gunshot wound of the shoulder. He complained of pain in the neck. The wound was discovered only after careful search, and consisted of a tiny scab in the neck, above the inner end of the left clavicle, about an eighth of an inch in diameter. There was no other physical sign except some tenderness on deep pressure. Had he not consistently complained of pain, and at times given the impression of undoubted suffering, he would have been sent to rejoin his unit almost immediately. However, a few days after admission there appeared gradually a small red swelling, hard and tender to the touch, in the neck just behind the inner end of the left clavicle. There was no pulsation. The classical error

was committed, and "abscess" diagnosed. An x-ray plate revealed a tiny fragment of shell about the same size as the wound, deeply situated in the region of the swelling.

A small superficial incision was made over the red area, and a pair of artery forceps pushed deeply into the supposed abscess. No pus appeared. The finger was then introduced, and the deep parts of a small cavity being disturbed, there followed an alarming gush of blood, easily controlled, however, by pressure of the tip of the finger on the pulsating artery, in the anterior wall of which there apparently was a tiny wound.

The remaining part of the operation was performed with the tip of the left index finger on the artery at the bottom of the wound, an assistant retracting and ligating, an orderly pulling the left arm downwards and the anaesthetist forcing the head firmly towards the right shoulder. A long incision was made transversely across the neck, just above the clavicle and including the original opening. The dissection which followed was naturally long and tedious, punctuated by various "alarms and excursions." The clavicular head of the sterno-mastoid was cut across. The suprascapular artery and various veins were ligatured and divided. The inner margin of the scalenus anticus and the thyroid axis artery were recognized. The latter was followed to its origin from the subclavian, and the finger tip on the puncture was just internal to the point of origin. With as little disturbance of the subclavian as possible, and after a little blunt dissection, two pairs of artery forceps were applied to the artery close together, and these occluded the puncture and controlled the hæmorrhage. An aneurysm needle was passed round the artery, first immediately internal to and then immediately external to the forceps, and the vessel was ligated in two places with thick catgut.

The wound was stitched and a small drainage tube was left in position for twenty-four hours. The arm was wrapped in cotton wool and placed in a modified Thomas's arm splint in the horizontal position. No complications arose, the wound healed by first intention, and the patient was evacuated to England within three weeks.

DERMATITIS CAUSED BY BITTER ORANGE.

OCCASIONAL dermatitis due to the handling of certain flowers and plants is well known, but cases are not very common, so that they may be rather difficult to recognize. In *Sequeira's Diseases of the Skin* is given a list of over forty plants which are known to have caused dermatitis. Among them is the bitter orange, and several cases of this form of dermatitis recently came under my notice among girls engaged in peeling bitter oranges in a jam factory.

The most marked case was that of a girl, aged 25, who suffered from a very acute dermatitis of the fingers, hands, and forearms, and also of the face. There was intense erythema and much swelling, especially of the hands and forearms, the parts most exposed to the juice. There were numerous small vesicles, a little larger than the size of a pin head, all over the affected areas. I put the patient to bed for one week and applied a lotion of zinc carbonate, pulv. calaminæ and aq. calcis, which proved very effective, the inflammation entirely disappearing after ten days. Idiosyncrasy evidently plays a considerable part in the condition, as in spite of all precautions the girl in question had ultimately to give up the work.

Glasgow

F. ANDERSON MCPHAIL, M.D.

A STELE in memory of the internes of the Paris hospitals who died on active service during the war has been erected at the Hôtel-Dieu. On it are inscribed 72 names, it is ornamented by a bas-relief in the post.

AT the meeting of the Société de Médecine, Strasbourg on October 3rd, the Minister of War will be presented with a medal in recognition of his patriotism during the German occupation.

THE tuberculosis mortality at Rio de Janeiro, which in 1903 was 4.43 per 1,000, rose to 5.53 in 1918, and is now 10 per 1,000. Amaury de Medeiros, general secretary of the Association for Combating Tuberculosis in Brazil, estimates the annual number of deaths from tuberculosis in Brazil at 60,000, and the number of cases at 600,000.

Reviews.

AN ATLAS OF OBSTETRICS.

IN his *Atlas of Normal Labour* Dr. DRUMMOND ROBINSON has reproduced a large number (405 to be exact) of the diagrams and photographs which went towards the constitution of the "animated diagrams" and motion photographs introduced by him to the profession a year or more ago. It will be recollected that he demonstrated these before a meeting of the Obstetrical and Gynaecological Section of the Royal Society of Medicine in November, 1919, and since then they have been shown in other centres. At that time (November 15th, 1919) we referred to the exhibition of the films, and generally to the use of the cinematograph in medical teaching. Now it remains only to say that the publication of the atlas will help to convey to many who have not had the opportunity of seeing the pictures in motion some idea of the nature of the teaching which can thus be given. Present prices make the purchase or even the hire of the films possible only for large classes, but the salient features may be picked out in the atlas in the tutorial class and made the pegs upon which to hang much practical teaching.

The *Atlas* affords an interesting opportunity of studying at leisure the individual pictures, and so minute are the differences between the consecutive diagrams of a series (and probably they are far from being consecutive in the film) that one is lost in admiration of the care and patience on the part of the author and artist which must have gone to make them so successful and (in the case of the diagrams) so lifelike. The photographs, like all surgical photographs, suffer from the obscuration of the field by blood, which appears a dense black in colour. Apart from this unavoidable drawback they are excellent.

This is a book to be welcomed—perhaps not so much for what it contains as for what it is. For it is a pioneer book, and years hence will be looked back upon with interest by those who regard the cinematograph as a regular part of the stock-in-trade of the teacher of the practical branches of medicine and surgery.

INJURIES OF PERIPHERAL NERVES.

Able exposition of what is to be regarded as representative of the work of the German school of surgeons on injuries of peripheral nerves has been issued from the clinic of the university of Göttingen. The author, Dr. WALTHER LEHMANN, has dealt with the subject from its civilian and military aspects, but as in all countries, the experiences of war surgery are rightly allowed to dominate the whole essay.² It is interesting to note the complete absence of any reference to the work done in countries other than the Central Powers, although a very extensive bibliography is included. This omission is probably an advantage, as it allows the reader to formulate a sure opinion as to the attitude of the German school towards this important section of reconstructive surgery, and to make comparison between it and that of the French and British surgeons and neurologists. We arrive at the general conclusion that, allowing for minor differences, this surgical field has developed along parallel lines in all countries.

A short but clear account is given of the main principles involved in the healing of nerves, and of the pathogenesis and the symptomatology of nerve injuries. It is stated quite simply, but without undue dogmatizing, that recent work has strengthened the peripheral theory of regeneration, and that the constant topographical anatomy of peripheral nerves established by Stoffel has not been confirmed by the work of Borchardt and others.

In discussing the operative repair of injured nerves the author emphasizes the reasonableness of a conservative attitude, and in lesions of the complete anatomical type, where nerve suture is indicated, he is insistent on the necessity of obtaining end-to-end apposition at all costs,

even if the line of section of the nerve stumps passes through tissue which is far from ideal. The operations of nerve grafting, tubulization, repair by flaps, and anastomosis are dealt with fairly in view of the isolated reported successes, but one is left in no doubt as to the general consensus of opinion in Germany on their inapplicability in practical nerve surgery. In discussing the prognosis of nerve repair emphasis is laid on the superiority of the regenerative process in young people, and this is assumed, although without any statistical support, to be one of the determining factors. Stress is laid also on the importance of early suture, and this view is supported by conclusive statistics from the civilian and war literature.

The available statistics of recovery after suture in warfare injuries are comparatively few in Germany, and the author adopts a pessimistic tone as to the general chances of adequate recovery, except in the case of the musculospiral nerve. Secondary re-exploration for failures is not considered worth while, except where the previous operation was a neurolysis, and resection and suture is indicated as a primary measure. The value of alternative operations in irreparable injuries is discussed lucidly, and considerable space is allotted to a technical description of the tendon transplantation operation for irreparable musculospiral injuries as introduced by Perthes. In this, tenodesis of the wrist is an essential step, and the operation differs considerably from the classical British operation, which has never been improved upon in any country.

This work is well illustrated, and British readers will be grateful for a simplicity of style long considered to be an unusual feature of Teutonic surgical literature. In some ways it is probably the best balanced essay on this subject which has yet been produced, and it can be recommended to the serious attention of all surgeons who are interested in this particular field.

PARTIAL OPERATIONS ON THE PROSTATE.

Dr. LIONEL ESCAUDE is a disciple of Luys and an enthusiastic advocate of the latter's treatment of hypertrophy of the prostate by "forage." His publication *Le Forage de la Prostate*³ begins with a historical summary of our knowledge on the subject of prostatic hypertrophy. In it special stress is laid on the frequency with which a prostatic bar constitutes the only obstacle to micturition. By the destruction of this bar a free outlet is provided for the passage of the urine. After passing in review the various partial operations, such as those of Bottini and Goldschmidt, which have been advocated for enlargement of the prostate, the author describes in detail the technique of Luys. The work of destruction is carried out through a Luys's direct cystoscope by means of a special electrode connected with a diathermy apparatus. The precise form of apparatus recommended by the author is that of D'Arsonval, which is simple and makes it possible to regulate accurately the intensity of the current. The technique of Luys's operation is well described, the text being reinforced by the addition of excellent illustrations. The author regards as contra-indications to the method the presence of sepsis or the existence of a great enlargement of the entire prostate. He states that the method is specially applicable to younger men showing very little change except the existence of a prostatic bar, and also to old cases with dangerous involvement of the kidneys. In only three cases out of a very large series did difficulties of micturition recur, and in these further treatment by means of "forage" sufficed to remove their troubles. The book concludes with details of 63 cases treated by these means. An analysis of the first 49 showed that the following types of operation were required: In 20 cases the removal of the prostatic bar, in 2 cases the treatment of the lateral lobes only, in 27 cases the removal of the bar associated with treatment of the lateral lobes. In 90 per cent. of the cases excellent results were obtained, frequency, pain and difficulty entirely disappearing. In 6 of the cases treatment had to be given up on account of the greatness of the enlargement. Altogether the book furnishes an excellent monograph on the subject of partial operations on the prostate. Although the author is an enthusiast, he nevertheless treats the subject in a fair spirit.

ANAESTHETICS.

*The American Year Book of Anesthesia and Analgesia*⁴ contains some valuable papers on physiological questions besides a number of contributions dealing with purely clinical matters. The latter are very largely concerned with anaesthetics in military surgery and have been put before us comparatively recently by many writers, including the authors represented in the *Year Book*. Among the other clinical contributions is a valuable paper from the Mayo Clinic by F. A. Willus. Although the number of cases dealt with is not very great, the accurate and detailed observations give weight to the definite opinions expressed. Willus deals with the operative risk in heart lesions under anaesthesia. His cases are classified in six groups—auricular fibrillation, auricular flutter, impaired auriculo-ventricular conduction, impaired intraventricular conduction, mitral stenosis, and aortic lesions. They include "the first proved case of flutter coming to operation." In his summary the author states that "the general tendency is to require too great a margin of cardiac safety in surgical work." F. C. Richardson also writes on heart lesions in relation to anaesthesia. He deprecates the use of scopalamine and thinks that spinal analgesia should not be used in any patient who cannot stand a temporary fall in blood pressure of 50 per cent. "More heart cases require rest after the operation than require stimulatives" is one of his conclusions. Embley contributes a paper on the physiopharmacology of ethyl chloride, proving experimentally the lowering of blood pressure by this drug and its effect on circulation through the vagus and peripheral dilatation. The importance of temperature in relation to anaesthesia is treated by Shipway and Pembrey, whose work has already been fully recorded in this country. Davis and McCarty, discussing the relative value of so-called warmed and unwarmed ether vapour, are diametrically opposed in some of their conclusions to the opinions of the above-mentioned observers. Crile's paper on an experimental research into the nature of nitrous oxide and ether anaesthesia contains his views on acidosis and anaesthesia, which are well known. The sitting position in nose and throat surgery, always a favourite with some operators in Great Britain, receives reasoned support from Denman and McKesson and W. H. Roberts. These articles are elaborately illustrated. Blood changes under anaesthesia and circulatory disturbances under anaesthesia are the subject of a number of good papers from Mann, Casto, Polak, and others, and low levels of carbon dioxide and alkali during ether anaesthesia are discussed by Yandell Henderson. The volume covers a wide field of work, and contains much of interest both to the practical anaesthetist and to the laboratory worker.

In his *Précis de Rachianesthésie générale*,⁵ G. LE FILLIATRE gives an admirably clear account of his method of spinal anaesthesia, and of the anatomical and physiological grounds on which he has based the procedure. His plan is fundamentally different from the usual spinal analgesia. He does not aim at a local influence but at a general paralysis of all the posterior roots. This he achieves by the use of a dilute solution of cocaine (1 in 50), which he employs in a manner that is, according to his account and experience, free from risk. Cocaine, of course, in ordinary spinal work has long been given up as too dangerous. Le Filliatre maintains that all risk in spinal injection and all serious conditions following an injection are due to hypertension of the cerebro-spinal fluid. This is caused by excessive secretion due to the introduction of a liquid which irritates the arachnoid membrane. He avoids this hypertension by first of all allowing 25 to 30 c.cm. of the cerebro-spinal fluid to escape before he makes his injection, and secondly, by using an injection of dilute cocaine solution in a particular manner. This manner is described under the term *barbotage* (*barboter*—to dabble or paddle). It consists in allowing the syringe to fill again after the injection has been made, then reinjecting this amount of cerebro-spinal fluid, then allowing it to fill the syringe, again, and then reinjecting once more. In this

way his original dose of dilute cocaine (3 to 6 cg. of cocaine in a 1 in 50 solution) is still further diluted with cerebro-spinal fluid before it is diffused. The spot chosen for the puncture is the lumbosacral space, the interval between the fifth lumbar and first sacral spinous processes. Here he finds the greatest diameter antero-posteriorly of the subarachnoid space, and the least chance of damaging nerves which are here closely related to the walls of the space, not freely passing through it. A preliminary injection of "hyposcsthésine," which contains scopalamine, morphine, strychnine, and sparteine, is an essential part of the method. Chemically pure cocaine hydrochloride is used, and the solution is either made at the time with sterilized distilled water or obtained from ampoules containing 6 cg. of cocaine. This dose gives an anaesthesia of the upper regions of the body, including the head, lasting three-quarters of an hour to one hour. The *Précis* is very clearly printed and the illustrations are both artistic and helpful.

LUCIANI'S "HUMAN PHYSIOLOGY."

THE fifth and final instalment of the English translation of the late Professor LUIGI LUCIANI's standard work on *Human Physiology*⁶ has been edited by Professor M. S. Pembrey, and appropriately so, for it deals with metabolism, temperature, reproduction, the stages of life and death, and the races of mankind. The first volume of this translation appeared ten years ago, the second in 1913, the third in 1915, the fourth in 1917, and the final one now sees the light nearly two years after the distinguished author's death in his eightieth year on June 23rd, 1919. The disadvantages of this delayed publication are obvious, and no doubt are in part contingent on the great war, but the translation has been fortunate in its editors—Dr. M. Camis, of Pisa, responsible for the first and second volumes, and Dr. Gordon Holmes for the instalments on the muscular and nervous systems and the sense organs. In our previous reviews the excellence of Miss Frances Welby's translation, which recalls the charming style of the late Sir Michael Foster's textbook, has been emphasized, and, although the name of the translator of the final volume is not revealed, the high standard thus set up has been well maintained.

The history of experimental metabolism is sketched from 1614, when Sanctorius's book, *De Medicina Statica Aphorismi*, appeared at Padua. As they are not described elsewhere the editor has added a brief note on vitamins, but has referred the reader to Professor Hopkins's papers and the Medical Research Council's special report series for further information. The chapter on the theory of human nutrition contains a full description of Chittenden's observations, including those on the late Horace Fletcher, who maintained his health and weight on less than half the daily protein intake as estimated by Voit, and their importance as an argument for economy in nutrition is emphasized. The view put forward long ago by the late Sir Henry Haldane in his essay on "The Climacteric Disease," that in males there is a critical period of from one to four years corresponding to the menopause in women, and in 1910 attributed by Mendel to diminished secretion (? internal or external) of the generative glands, is dismissed, on the ground that of the observations upon which it rests a large proportion can be explained as casual morbid symptoms arising from causes quite distinct from those suggested by Mendel. After a full and fair presentation of Metchnikoff's well known conception of the harmful effects of enterogenous bacterial toxins and macrophages, it is shown that old age is not a morbid process due to auto-intoxication, and that it is, therefore, useless and erroneous to expect that fermented milk and hygienic precepts, excellent as they may be in themselves, will prevent the inevitable process of physiological involution.

There is an interesting historical summary of the problem of death; life and death are not separated from each other by any exact boundary, and, in spite of much research, the precise moment of death cannot be fixed in single tissues except by rigor mortis in the muscles. The immediate cause of death is always intrinsic to the

⁴ *The American Year Book of Anesthesia and Analgesia*, 1917-1918, Edited by F. H. McMeekin, A.M., M.D. New York City: Surgery Publishing Co. 1921. (Demy 4to, pp. 483; 175 figures. 10 shs.)

⁵ *Précis de Rachianesthésie*. By G. le Filliatre. Paris: Librairie E. le François, 1921. (Imp. 16mo, pp. 125; 22 figures. Fr. 8; post free, Fr. 8.80).

⁶ *Human Physiology*. By Professor Luigi Luciani, Director of the Physiological Institute of the Royal University of Rome, with a Preface by Professor J. N. Langley, F.R.S. Vol. V: Metabolism, Temperature, Reproduction, etc. Edited by Professor M. S. Pembrey. London: Macmillan and Co. (Med. 8vo, pp. 422; 158 figures. 39s.)

organism as a whole, even when brought about by some external agency, but is extrinsic to the elements of a large number of the tissues, being due to functional failure of the organs and tissues essential to life, and spreading from them, so that all the parts of the body do not die at the same time. The last chapter, dealing with ethnology and anthropology, has been contributed by Professor S. Baglioni, and contains some excellent photographs of the different human races. The illustrations, a number of them coloured, and the general get-up of the work, are alike admirable.

LUNACY IN INDIA.

Dr. A. W. OVERBECK-WRIGHT, the author of *Lunacy in India*,⁷ is the Medical Superintendent of the Agra Asylum, and Lecturer on Mental Diseases to King George's Medical College, Lucknow. He has had a wide and varied knowledge of the East during a period of nineteen years, and thus writes on a subject in respect to which he has had a vast experience. While his book contains some details of general psychiatric interest its title is perhaps not quite expressive of its aims, as it is primarily a textbook designed for the use of the practitioner in India. It contains the usual subject-matter of the conventional textbook, together with an account of special legal points and methods of certification peculiar to the country to which it refers.

The provision for the suitable treatment of the insane in India is evidently far from adequate, since the author states that in an area with 67,836 insane there is only asylum accommodation for 7,234 patients. After naming the reasons for this deficiency, he expresses the hope that local sects and bodies will form institutions of their own as they become more enlightened as to the nature and causation of insanity. In the Census Report for 1911 the proportion of insane to general population is noted as 26 to 27 per 100,000, a figure which compares well with that of 364 per 100,000 for England and Wales. The difference is, however, more apparent than real, as the Indian statistics do not include the weak-minded, and for this and other reasons an accurate survey would probably approximate much more closely to the English percentage. The author raises many points of interest, and amongst them he notes that in India the use of opium, a drug which is there usually taken in pillular form, does not produce any conspicuously evil effects. There is no tendency to the marked mental and physical decay which is observed so commonly amongst those who smoke it, or who take it by injection in the form of morphine. Cases of insanity due to its consumption are practically unknown.

The section devoted to clinical psychiatry is well written, and the author lays stress on the physical aspects of mental disorder. He follows the classification of Dr. Lewis C. Bruce, with whose views he is in accord as to the importance of toxic factors in the production of many forms of insanity. The various clinical groups are described in detail and illustrated throughout by reference to actual cases. We can thoroughly recommend this book, which would seem to meet a definite need. The practitioner in India will find in it a reliable guide in dealing with cases of mental disorder in both their legal and medical aspects.

"THE MEDICAL ANNUAL."

The Medical Annual,⁸ now in its thirty-ninth year, fills a niche of its own in the medical library. It is the sort of book that one likes to have at hand and into which one can dip at any time—for a few minutes or for an evening—with pleasure and with profit. The first part contains a dictionary of materia medica and therapeutics by Dr. Frank J. Charteris, and although he finds that "the year under review has not been fruitful in important work" in therapeutics, there are useful notes on protein therapy and other subjects. Included also in this part is a concise review by Dr. Thurstan Holland of developments in radiography and electro-therapeutics. The second part of the *Annual* is a dictionary of treatment, composed of numerous notes and articles summarizing medical and surgical progress in 1920 by some thirty contributors. Among the most interesting are those on deficiency diseases by Dr. J. A. Nixon;

on the blood by Dr. O. C. Gruner, which is illustrated by some remarkable coloured diagrams; on psychological medicine by Dr. J. A. Hadfield, which gives a sane and readable account of psychotherapy; and on encephalitis lethargica by Dr. Ramsay Hunt, which covers the most recent researches on this disease. The article on orthopaedic surgery by Dr. Fred. H. Albee and Dr. R. F. Carter of New York is an admirable and well illustrated review, which does not over-emphasize, but does not suppress, the personal opinions of the authors. A useful survey of recent work on the surgery of the stomach is contributed by Mr. James Sherren. To simplify reference for readers all advertising matter has this year been removed from between the title-page and the body of the work. At the end of the volume are useful lists of new medical preparations and appliances, the principal medical works published during the year, medical institutions, sanatoriums, and nursing homes, and the principal British spas. There is also an official and trade directory, which includes lists of the medical and scientific societies and periodicals. The volume is well illustrated, in black and white and colour, and admirably indexed.

THE ANNALS OF MEDICAL HISTORY.

The first part of Volume III of *The Annals of Medical History*,⁹ containing nine interesting articles, editorials, notes and book reviews, sets a standard of printing and reproduction of illustrations that must compel our admiration and envy. The opening article by Dr. J. Collins Warren on the collection of the Boston Phrenological Society, which flourished for ten years, being founded on the evening of the funeral of Spurzheim (1776-1832), who died in Boston from typhoid fever, endorses the growing modern opinion that, though much obscured by their advocacy of phrenology, Gall and Spurzheim's painstaking work really entitles them to a place among the pioneers of research leading up to the modern conception of cerebral function. Dr. L. M. Griffiths, of Bristol, writing on Shakespeare and the practice of medicine, shows that the extravagant claims for his insight into matters medical cannot be allowed, and that the statement that he always paid respect to the profession is not borne out by his references. An ancient Egyptian prescription for hysteria on an ostrakon in the Metropolitan Museum of Art, New York, dating from about 1500 B.C., is described by Dr. I. H. Coriat, and this article is followed by Dr. H. B. Jacobs's address to graduating nurses on Elizabeth Fry, Pastor Fliedner, and Florence Nightingale. Dr. J. C. Hemmeter gives an account of Leonardo da Vinci as a scientist, and Dr. J. H. Skavlem deals with the scientific life of Thomas Bartholin. Dr. D. A. Wells rightly says that Sir William Osler's life-story may well prove a benediction to those in the daily grind who seek equanimity of soul, and that, as a great man has been defined as several men in one, he finds in Osler three—the man of science, the man of literature, and the man of philosophy. Short articles on an Assyro-Babylonian treatise on diseases of the male genito-urinary organs and on the giving of medical degrees in the Middle Ages by other than academic authority are contributed by Dr. E. Podolsky and by Dr. H. Friedenwald. Among the book reviews there is a full and eulogistic notice of Dr. R. Hingston Fox's *Dr. John Fothergill and His Friends*, which was reviewed in our columns on June 14th, 1919, p. 739. The portrait on the cover of this number of the *Annals* is one of Raymond Vieussens (1634-1713) from Montpellier, provided by Dr. C. Greene Cumston, who corrects the oft-repeated error that this famous anatomist was a professor of the subject.

NOTES ON BOOKS.

The New Pocket Medical Formulary,¹⁰ by Dr. W. E. Fitch, is a compendium of prescriptions, diet lists, tables of differential diagnoses, dose lists, and similar items, intended for the physician, student, and pharmacist. The little book is now in its third edition, so that it has evidently appealed successfully to the public for whom it is intended, and many of its formulæ are certainly valuable. But when, in a volume published in the year 1921, we read in

the paragraph devoted to the subject "Peritonitis" that "the patient must be kept under the influence of opiates for two days at least," we are a little apt to overlook many of the other merits of the volume.

A surprisingly large number of scientific workers are unable even to join a glass tube or make a T-piece that will not crack spontaneously, and it is to them that the *Handbook of Laboratory Glass-blowing*,¹¹ by Mr. BERNARD BOLAS, is addressed. A complete outline of the methods used in making commercial apparatus is not attempted, but by following its many valuable directions and hints the student should achieve increasing success in his efforts to manipulate glass in the laboratory.

APPLIANCES AND PREPARATIONS.

An Anaesthetist's Screen.

DR. C. A. STIDSTON (Wolverhampton) writes: The following is the description of an anaesthetist's screen which I have recently devised. It consists of an upright tube 11 in. high, which can be screwed firmly on to any table; out of this telescopes a second tube 10 in. in length, on to which another tube 13 in. in length screws at right angles, and from the latter telescopes a fourth tube 21 in.

in length. By adjusting these tubes and their controlling screws in a vertical and horizontal direction a towel rail from 11 in. to 20 in. in height and 14 in. to 36 in. in length can be fixed at any angle across the patient's body.

While primarily intended for use in operations on the neck and chest under general anaesthesia, the screen can be used also for operations on all parts of the body below the head under local anaesthesia. The component parts are light in weight and pack easily into a small compass. The screen has been made by Messrs. Down Bros., St. Thomas's Street, Borough, S.E.

PHYSICAL SCIENCE AND THE LIVING ORGANISM.*

BY

A. V. HILL, Sc.D., F.R.S.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF MANCHESTER.

This lecture is meant to deal more with the general spirit than with the precise details of scientific methods applied to the problems of the living creature. Thirty or forty years ago a speaker on this subject might have tried to convince his audience of the advantages of a materialistic philosophy of life. If he had not done that, he would probably have "sided with the angels," and attempted to persuade them that the orthodox Christian faith was a sufficient account of the mysteries of life. It is only ten years ago that I attended a crowded lecture at Jena, in which William Ostwald the chemist, incited by Ernst Haeckel the biologist, reduced the whole world, conscious and unconscious, to manifestations and transformation of energy. Mine is a much humbler rôle. I shall not try to convince you that you and I are merely complicated systems of electrons, whirling away for a little while and in a moderately stable manner, on the road leading from the nothing whence we came to the nothing whither we go. I shall not attempt to mystify you, as Haeckel did our fathers, with the blessed

word "protoplasm." Neither shall I ask you to believe that the consciousness which we call You and I is merely an elaborate and convenient mechanism designed by natural selection to render our journey on that road a little longer and more comfortable, and our end less sudden. Nor shall I try to persuade you that intellect, goodness, beauty, and all the things that men strive after, are nothing but general relations of a physical universe, evolved somehow to secure the survival of the human species. Indeed, I want to persuade you of nothing more romantic than the advantages of exact scientific methods of studying the behaviour of the living creature.

The living creature is a very strange thing. Here it is in a physical, material, mechanical, chemical universe showing the most extreme dependence on physical conditions. It dies if it be frozen, or boiled, or deprived of food; it does not like strong acids, or ultra-violet light, or x rays, or trivalent positive ions; its properties depend to a most extraordinary degree on those of water; it conducts electricity; it obeys the laws of motion, of the conservation of energy, of the conservation of mass; and yet at the same time it shows, in its simplest forms, a complexity, an apparent purposefulness, an individuality, defying any physical hypothesis. One could treat a chemical theory of consciousness, or a physical theory of heredity, or a mechanical theory of intelligence, only one degree more seriously than the instruments recently designed by Mr. Edison for facilitating telephonic communication with the next world. And yet, deprive the brain of oxygen for a few seconds and consciousness is gone; remove the thyroid gland and a beautiful and intelligent child becomes a hideous imbecile; subject the egg-cell of some species to an appropriate salt solution and an individual will develop without a father. The absence of certain chemical bodies prepared inside the body by the thyroid gland, the lack of oxygen to carry on certain necessary combustions in the brain cells—both simple chemical changes—have obliterated the essential characters of the highest form of life. Wherever we look we find life in only one form, composed of compounds of hydrogen, oxygen, nitrogen, and carbon, living between certain narrow limits of temperature, giving out exactly as much energy as it takes in, dependent on the supply of foodstuffs from outside, exhibiting certain electrical properties, poisoned and destroyed by the most absurdly small doses of certain chemical substances. It is clear that the living creature does depend largely on purely physical factors. Largely, but how far?

Consider the case of heredity. The union of two cells starts off a developing organism, as small as a flea, or as large as a whale, in most respects very like its parents, but in some very unlike—a separate individual. We are so used to this recurrent miracle that most of us regard it as a commonplace; you would not regard me as speaking seriously if I said that I am daily amazed by the fact that the offspring of man is man, when it might have been an ox, an onion, or a tree. Consider all the complexity of a man—his elaborate physical body; his intricate, sentimental, adventurous mind; his extreme stupidity in examinations; the subtle inheritance of voice and manner, of colouring and movement, of aptitude of body and mind; all alike from one generation to another, yet with ever-varying individuality; all inherited through a little cell which bears to a tadpole the same relation as a second to a lifetime. Add to this the faculty of handing on the same characters to countless successive generations. Adopt the purely physical theory of life, and all future history is wrapped up in a little cell so small that you cannot see it at all without a microscope. It would seem inconceivable that any man should attempt to build a physical or chemical theory of inheritance.

Or, again, take the case of consciousness, our awareness of things, our conviction of free-will and self-determination, despite all the arguments of philosophers. Is it conceivable that the most ingenious designer of instruments could make a penny-in-the-slot machine possessing, even for a moment, this type of consciousness? And yet, apply a simple physical change—turn on the gas in his bedroom, give him a few milligrams of a salt with a positive trivalent ion, deprive him of oxygen, raise his temperature a few degrees, and all the elaboration, all the sentiment, all the stupidity in examinations, all the power of carrying on the inheritance, are gone. Where—if anywhere—does physics end, and where—if anywhere—do we come up

* A public lecture delivered at the University of Manchester.

against the fundamental biological and spiritual realities of life? I cannot answer that question, and all I shall try to do is to show that attempts to answer it are not profitable; indeed, that progress in the knowledge of the living creature comes largely, and will come mainly, from attempts to solve it by the methods and tools, mental and material, of the exact sciences. And remember that progress in our knowledge of the living creature means progress in medicine, in industry, in agriculture, in sociology, in all departments of life. Our ignorance of the living creature is very great, and we can overcome our ignorance, not by theoretical discussions, not by dogmatical assertions, not by hypotheses founded upon insufficient evidence, but by the methods and tools of the exact sciences, by the aid of the finer tools which they employ.

Physiology has three main functions—two very practical, one very philosophical. As the handmaid of medicine, and as the science of the behaviour of the normal living man, physiology has a great and practical part to play in national and social life. At the same time, however, physiology has its great intellectual part to play in attempting to describe the mechanisms underlying the manifestations of life; it is only this latter which we are discussing here. It may be asked what is meant by a mechanism, and how one would propose to study it. Before attempting to illustrate what I mean by a mechanism, let me give you a picture of a man as a community of a myriad living cells, each to some degree independent, each bound to the rest by ties of necessity, convenience, pride, comfort and inheritance. You—your personality as a whole—are the People, the Demos, the aggregate-expression of the individual lives of all the little cells which make you up. You—your personality as a whole—express yourself more or less imperfectly by your representatives—the cells of your brain, meeting in parliament inside your skull. You—your personality as a whole—have a national pride and consciousness, expressed to some degree by your representatives. You decide, as a nation decides—goodness knows why!—to assault your neighbour. What happens? Your representatives, your government, the highly differentiated nerve cells of your cerebral cortex, interpreting your aggregate imperfectly expressed dislike of your neighbour, proceed to send a message to the various government departments—what we call the self-protective reflex centres (note that it is always self-protective)—ordering them to carry on. From that moment the War Office, the collection of reflex centres of the nervous system charged with “self-protection,” proceeds to take charge of all the movements and activities of the community. Various lower and more automatic centres are called into play. . . . y. we come down to the individual fighting unit—the private soldier, the muscle cell with its simple functions, depending upon orders received along the nerves for its co-ordinated activity.

Now suppose that a nation is involved in such an affray, and that a visitor from another world has arrived with the intention of studying the organization and habits of the human race—a visitor who has never seen a man before and has not the least idea what he is like. He would not be wise, I think, to walk straight into Parliament, or into the War Office, or, indeed, into the Senate of this University, in order to study the organization in its full complexity; he would be much wiser, I think, to seek out an individual citizen, or an individual soldier, and to make a preliminary study of the simple common man. Having gained a conception of the behaviour of the simple common man, his need of sleep, of beer and tobacco, of oxygen, of companionship, his prejudices and his enthusiasms, he would be better fortified to proceed to study the organization of the State as a whole; for, after all, the properties of the State depend upon those of its fundamental unit—man. Similarly the properties of man depend upon the properties of the little cells of which he is built up, and his behaviour is the aggregate-expression of their behaviour. Now, what properties have these cells? The outward manifestations of their properties are exclusively physical—they move, they divide, they take in food and water, they absorb energy and they give out heat; presumably there is some

cause for all these manifestations, so we attribute a mechanism to a cell. The mechanism of a cell is the cause; the means, of the physical manifestations of the cell's activity. In talking of a mechanism inside a living cell, in talking of the mechanism of life, one is not affirming that life is nothing but mechanism; one is assuming—what is obvious—that many of the manifestations of life are physical, and that these physical manifestations must have a physical cause.

Let us consider shortly the properties of the living cell, the unit of which the community of the living man is made. The living cell is very small—a million million or so to a cubic inch—and it is necessary to employ a microscope to study its structure. It is so small that most physical methods cannot be applied to the single cell—we have to employ a large number of similar cells at a time. It is surrounded by a membrane possessing certain physical properties. It contains a nucleus concerned in some mysterious way with the continued existence of the cell and its power of subdivision. It requires food and oxygen; it gives out energy and CO_2 ; it needs salts and water; and it shows many highly specific chemical properties. Some cells—the cells of the green plant—can absorb the radiant energy of sunlight and store it as the chemical energy of oxygen and starch; without this property of taking up energy from the sunlight the world would be a dead world, with no possibility of life and thought. The cell obeys—so far as we know—all the physical and chemical laws governing our universe. And yet it shows a kind of independence, a degree of complexity, an apparent purposefulness, which makes it difficult to fit into any simple physical system. We know, of course, that science is still very young; the theory of relativity and modern views of electro-magnetic phenomena tend to show that all our simpler conceptions of time and space, the laws of motion, of the conservation of energy and mass, are only good first approximations to some more fundamental reality. To assert that present-day physics can supply an account of the behaviour of the living cell is simply to state what is obviously not true; but will physical science ever be able to supply such an account? In the last resort I believe it will not. This, I admit, is only a belief and not based upon definite scientific evidence. In the last resort, however, I believe it will be found that the living cell, or some arrangement of atoms containing the same kind of purposive, selective properties, has existed as long as matter, that it cannot originate from matter alone, but always had another cell before it, and that in some kind of way, and to some degree, the spiritual nature of the universe is reflected in the behaviour, the life and structure of the living cell.

One function—the chief function—of science is the discovery and formulation of exact laws. Do not imagine that the so-called exact sciences have a monopoly of exactly obeyed laws. Biology, the science of the living creature, has several laws to which no exception has been found. Every living cell comes from a living cell: the offspring resembles the parent: all living creatures appear to have originated from some common stock in the very distant past: every organ has a counterpart in other types and species: certain characteristics are inherited according to exact mathematical rules discovered by Mendel and amplified by Bateson. These generalizations have the same dignity as the conservation of energy or the laws of motion. One side of the work of the biologist is to trace out and establish these generalizations of biology by the methods of biology, by the observation of the behaviour of living cells, their ways, their inheritance, their abnormalities. The task of the physicist and chemist, on the other hand, is to elucidate the general principles underlying the phenomena of the non-living world. The function of the physiologist lies between these two, to judge between the physical and the biological laws, to see how far the methods and generalizations of physical science can describe the phenomena of life, and how far it is necessary to invoke other laws—biological or psychological in nature but established like the former by careful and exact observation—to describe them.

I have purposely discussed so far the philosophical, the strictly scientific, side of the subject. The first duty of a university is to encourage the pursuit of knowledge, and knowledge can never be pursued profitably except by those who are primarily interested in knowledge for its own

snake. The "get-rich-quick" attitude will never work in science. Do not let me be misunderstood; I should be the last to discourage the useful applications of science or those whose interest lies primarily in such applications; I hold strongly to the belief that a knowledge of the theories and applications of science is a necessary part of any liberal education, and I feel that such applications—if wisely and cautiously made—are an essential element in the progress of mankind. What I do wish to emphasize, however, is the fact that science will become sterile if we eliminate those—comparatively few—whose interest is primarily in the acquisition rather than in the application of knowledge. Those who need the encouragement and stimulus of a great university most are those who are in the firing line of the army which is promoting knowledge; without the units of the firing line the army cannot progress, necessary indeed as are those who follow behind to clear up, to consolidate, and to utilize the ground acquired. With this provision, however, let us consider a few cases in history where a study of the physical and chemical properties of the living creature have borne fruit in practical experience.

Pasteur investigating the optical properties of certain solutions was led to a study of the chemical properties of organisms, and thereby created modern bacteriology, modern knowledge of disease, modern hygiene, modern aseptic surgery: not to mention the fact that he saved the beer and silkworm industries of France. The world has never, I suppose, had a greater benefactor than Pasteur—on the material side the results of his work are to be reckoned in millions of lives and in millions of millions of pounds, and in the world of thought his discoveries are of no less value because, through them, disease has, to a large extent, ceased to be an unknown mysterious malignant spirit and become a matter which (though still unfortunately affecting the human race) is more or less understood, more or less a matter-of-fact plain thing. All this discovery and progress has resulted from Pasteur's interest in the optical properties of solutions.

Let us take another case. Here in Manchester, when a certain chemical body was urgently required in large quantities during the great war for the manufacture of propellant, bacteria were invoked to do what men found some difficulty in doing. In the future I think there is little doubt that manufacturing chemistry will come more and more in touch with biochemistry, and that more and more the chemist will employ strains of bacteria to deal with the molecule in an individual way impossible to his ordinary mass methods, and so to carry on processes which would otherwise be difficult or expensive. For example, a large part of the combined nitrogen, which is an essential constituent of food and an essential factor in chemical industry, is fixed for us by micro-organisms living on the roots of plants. Man has tamed the cow and the horse, the dog and the cat, till they have become an essential part of his social organization; in the future he will have to breed and tame the micro-organism and teach him also to minister to human needs.

Or take another case. When a muscle contracts, when a heart beats, when a nerve sends a message to or from the brain, certain electric currents are produced. The origin of these currents remains as yet a mystery, but the attempt to explain them has been one of the chief occupations of physiologists for fifty years. When you wish to do something you send a message to some muscle or group of muscles telling them to contract; this message goes 100 yards a second, 200 miles an hour—not as fast as a telegram, not, indeed, as fast as sound, but still many times faster than an express train. I called it a message, but what is it? Something goes along the nerve, some event, leaving nothing behind it, but causing the muscle to contract at the other end. The one thing we know about it is that this something, this event, this message is accompanied by an electric change: the elucidation of the mystery of this message will carry us far in describing the mechanism of life. But I am discussing practical applications. In order to study these electric currents, the Dutch physiologist Einthoven was led to design his string galvanometer, an extremely sensitive and rapid instrument for measuring and recording electric changes. This instrument has proved of recent years one of the most fertile agents in elucidating the problems provided by disease of the human heart. Most of us die in some way and in

some sense of heart failure in the end, so that anything which improves our knowledge of diseases of the heart may well be considered a useful application of physical, in this case of electrical, science to the living creature.

A study of the chemistry and physics of respiration, undertaken largely in an attempt to solve the purely scientific question of whether oxygen diffuses of itself into the blood through the lung substance, or whether the lung substance seizes on oxygen, so to speak, and pushes it through, has led largely to the therapeutic use of oxygen in disease, to a knowledge of mountain sickness and of the effects of flying at high altitudes, to means of avoiding the disease known as caisson disease induced by working at high atmospheric pressure—as, for instance, when digging a tunnel under a river—and to a study of the ventilation of mines and factories and submarines. A study of the chemistry of foods and of the things that happen to foods after they have been taken into the body, has led us to a knowledge of the vitamins—the so-called necessary food factors without which the animal becomes defective in vitality, mentality and development, without which a population may become the prey of rickets, scurvy or beri-beri.

What further applications lie in front of us? The synthesis of a plentiful supply of foods adequate in all respects to maintain life for a continually increasing population; the more efficient utilization of the sun's energy; a knowledge of the mechanism of the cell—just as necessary to the wise physician as a knowledge of the mechanism of a watch to the wise mender of watches—the nature and production of specific immunity from disease: after all, is it really in the nature of things that all our children should have measles and mumps and whooping-cough? the production of chemical bodies with specific properties—like those of salvarsan—of destroying micro-organisms without destroying the body which they have invaded; the effects of radio-activity, of fresh air and sunlight: there is no limit to the practical applications of the study. Advance is coming quickly: with the aid of physical and chemical methods it is coming more quickly, but still not quickly enough. We want more workers, more apparatus, more laboratories and a wider scientific education of the people.

As I prepare to end this lecture, in which I hope I may perhaps have been privileged to communicate to others a little of my own pleasure in these things, I will revert once more to the interest of such investigations, as distinguished from their application. Mankind, one type of living creature, has been endowed with the power of thought and with an insatiable love of adventure. This love of adventure expresses itself in many cases in an insatiable curiosity as to how things work. It is a natural desire, and, I maintain, it is a good desire; it is a desire common to children of 3 and to old gentlemen of 80. How do things work? The living creature undoubtedly does work, in many and strange ways, but the problem of how it works is about the most difficult of all the problems man has ever set himself to solve. To answer it requires the highest experimental skill, the most delicate equipment, and a mind subtle enough to counter all the nasty tricks which the living creature will try to play on one. The problem is a very difficult one—how does the living creature work? But the difficulty only adds zest to the pursuit.

At the last German congress for internal medicine it was decided to establish an institute for testing the therapeutical value of new drugs.

MESSRS. WILLIAM HODGE AND Co. will shortly publish in their series of Notable British Trials a volume dealing with the case of Burke and Hare, edited by Mr. William Roughhead.

THE first meeting of the International Congress of Urology will be held in Paris from July 5th to 7th, under the presidency of Professor Legueu, with Professor Verhooze (Brussels), and Professor Brongesma (Amsterdam), as vice-presidents. The subjects for discussion are: (1) Nephritis, with uraemic syndromes: reporters, Hodge (Liège), Horder (London), Forbes (New York), Teissier (Lyons). (2) Remote results of wounds of the urethra: reporters, Kidd (London), Gardini (Bologna), Pasteau (Paris). (3) Pyelography: reporters, Lasio (Milan), Papin (Paris), Waters and Guy (Baltimore).

THE MACHINERY OF THE ASSOCIATION.

NOT all of those who read that section of the Annual Report of Council (printed in the SUPPLEMENT of April 30th) headed "Question of Efficiency of Constitution and Machinery of the Association" will realize the immense amount of work and experience which are there embodied, and for which the Association is indebted to Sir Jenner Verrall and his colleagues. The report could only have come from members who know much of the history of the British Medical Association and the changes its constitution has undergone during the past twenty years, and who are familiar with its working both locally and at the centre.

The object of the recommendations made is to bring the machinery of the Association up to date, and though the report is long it is not so formidable as it looks. Many of its numerous recommendations merely dot the i's and cross the t's, being verbal amendments of Articles and By-laws designed merely to remove obscurities. Others suggest relegating to the head office some of the detail work which has hitherto been done in part by the honorary secretaries of Divisions and Branches. An important subdivision of the report seeks to increase and define the responsibilities of Branch Councils. Before the present constitution was adopted in 1903 there were no Divisions and all the local work of the Association was done by the Branches in general meeting and by the Branch Councils. The scope of that work varied in accordance with local conditions and the energy and initiative of the Branches. All of them held clinical and scientific meetings, and all in varying degrees cultivated the social side. A few paid attention to medico-political questions and some dealt with ethical disputes. With the inauguration of the Divisions some of the Branch Councils which had hitherto been active felt that much of their *raison d'être* had gone, and their tendency has been to become bodies whose only concern with the Divisions in their areas is to distribute to them the grant received from the Central Council. But others have always felt it to be their duty to act in a sort of parental capacity to the Divisions in their areas, to try to co-ordinate their action so as to level up the local standards of remuneration and conditions of practice, to serve as arbiters in ethical disputes, and to stimulate those Divisions whose activity fell below the general level. The Council has come to the conclusion that all Branch Councils should be expected to take this view of their responsibilities. It is therefore recommending that all Division secretaries should be *ex officio* members of the Branch Council, that the Branch Council shall actively co-ordinate the work of the Divisions in its area, calling joint meetings of any of its Divisions to consider matters of common interest, and shall apply itself to the reorganization of any Division which may have become inactive, and act for such Division pending reorganization. As a corollary to this the Council proposes to take power to organize any inactive Branch, and to act for it, pending its reorganization. Realizing that no Branch or Division

can be really effective which has not adopted organization and ethical rules of procedure, it is proposed that no new group of members shall in future be recognized as a Branch or Division until it shall have adopted such rules, and that as regards existing Branches and Divisions the names of those which have not adopted such rules shall be reported annually to the Representative Body.

Another group of recommendations deals with the Representative Body; their tendency is to impress on Divisions the importance of exercising their right to appoint representatives. It is proposed to shorten the time within which representatives can be appointed; to provide that notice of election of representatives must be sent to the head office not less than six weeks before the Annual Representative Meeting; to impose on the constituencies the duty of electing deputy representatives; and to empower the Council, whenever it thinks desirable, to give separate representation to Divisions which have fewer than the standard fifty members. No one of the proposed changes is individually great, but collectively they will, if adopted, tend to accentuate the predominant position of the Representative Body in the constitution of the Association. In connexion with this section should be noted that part of the report which deals with the power of referendum to the Divisions where the Council differs from the opinion expressed by the Representative Body. The Council has carefully examined the present machinery and has presented an analysis of it. It has come to the conclusion that the only change to be recommended is one which makes it necessary for the Council to decide whether it will take a Referendum or not within one month of the meeting of the Representative Body, instead of, as at present, within three months. The change is one of form rather than of substance, for at present the Council meets immediately after the Representative Body and would undoubtedly make its decision on a matter of such importance without the delay even of a month.

The most striking change proposed in the report is in regard to the method of election of the Central Council. The Constitution Committee of 1900-2 was sharply divided as to whether the Council should under the new constitution be directly elected by the Representative Body or continue to be elected by the votes of members of Branches, singly or in groups. There is, of course, much to be said for the view that the Council is responsible to the Representative Body, and should be directly elected by it. To some this seems the strictly logical view, but in constitutional matters sentiment is often quite as important as logic. Moreover, the Branches have always elected some of the members of Council, and many members are averse from giving up this local election, in which every individual member can if he choose take a part, in favour of an election by the Representative Body acting as an electoral college. The result in 1903 was a compromise. The Representative Body has for some years elected 16 members of Council—12 by representatives grouped geographically in 12 groups, 4 by the representatives as a whole. The Council now proposes that these 16 shall be elected as follows: 12 by the representatives of England acting together, 1 by the representatives of Ireland, 2 by the representatives of Scotland, and 1 by the representatives of Wales. This, it will be seen, is a step away from the more localized grouping hitherto adopted, and if approved will diminish an objection often brought against the present method of election by the 12 groups—namely, that the number of representatives in the group is too small

British Medical Association.

EIGHTY-NINTH ANNUAL MEETING, NEWCASTLE-UPON-TYNE, JULY, 1921.

Patron: HIS MAJESTY THE KING.

President: The Right Hon. Sir T. CLIFFORD ALLBUTT, P.C., K.C.B., F.R.S., Regius Professor of Physic, University of Cambridge.

President-Elect: DAVID DRUMMOND, C.B.E., M.A., M.D., D.C.L., Vice-Chancellor and Professor of the Principles and Practice of Medicine, University of Durham.

Chairman of Representative Meetings: T. W. H. GARSTANG, M.A., M.R.C.S., D.P.H.

Chairman of Council: R. A. BOLAM, M.D., M.R.C.P.

Treasurer: G. E. HASLIP, M.D.

PROGRAMME.

The President, Professor DAVID DRUMMOND, will give an Address on Tuesday, July 19th, at 8 p.m.

The ANNUAL REPRESENTATIVE MEETING will begin on Friday, July 15th, at 10 a.m., and be continued on the following days.

The REPRESENTATIVES' DINNER will be held on Friday, July 15th, at 7.30 p.m.

The statutory ANNUAL GENERAL MEETING will be held on July 19th, at 2 p.m., and the Adjourned General Meeting at 8 p.m.

The Annual Dinner of the Association will take place on Thursday, July 21st, at 7.30 p.m.

Religious services will be held on Tuesday, July 19th, at 5 p.m.

The Conference of Secretaries will be held at 2 p.m. on Wednesday, July 20th, and the Secretaries' Dinner will take place in the evening at 6.30.

A Special Address on Industrial Medicine will be given by Sir Thomas Oliver, LL.D., M.D., F.R.C.P., on Wednesday, July 20th, at 8 p.m.

The Popular Lecture, on "Evolutionary Wounds," will be delivered by Professor Arthur Keith, F.R.S., on Friday, July 22nd, at 7.30 p.m.

THE SCIENTIFIC SECTIONS.

The Sections will meet from 10 a.m. to 1 p.m. Laboratory and Clinical Demonstrations will be given on Wednesday, July 20th, Thursday, July 21st, and Friday, July 22nd, between 3 p.m. and 4.30 p.m.

The following Sections meet on three days—Wednesday, Thursday, and Friday, July 20, 21, and 22.

MEDICINE.

President: Professor THOMAS BEATTIE, M.D., F.R.C.P.
Vice-Presidents: The Right Hon. LORD DAWSON OF PENN, G.C.V.O., M.D., F.R.C.P.; Professor A. J. HALL, M.D., F.R.C.P.; G. S. HAYNES, M.D., M.R.C.P.; J. WILKIE SMITH, M.D.

Honorary Secretaries: C. E. LAKIN, M.D., F.R.C.P., (105, Harley Street, London, W.1); W. T. RITCHIE, O.B.E., M.D., F.R.C.P.Ed. (14, Rothesay Place, Edinburgh); Professor W. E. HUME, C.M.G., M.D., F.R.C.P. (4, Ellison Place, Newcastle-on-Tyne).

The following provisional programme has been arranged:—
July 20th (10 a.m.).—Discussion: Visceral Syphilis, especially of the Central Nervous System and Cardio-Vascular System. To be introduced by the Right Hon. Sir CLIFFORD ALLBUTT, K.C.B., F.R.S., followed by Dr. Gordon Holmes, Professor Reynolds, Dr. John Cowan, Dr. A. G. Gibson, Dr. John Eason and Dr. Ivy McKenzie.

July 21st (10 a.m.).—Discussion: Asthma and Allied Disorders. To be opened by Sir HUMPHRY ROLLESTON, K.C.B., followed by Dr. John Freeman, Dr. A. F. Hurst, Mr. Frank Coke, Dr. Mackenzie Wallis and Dr. Charles McNeill.

July 22nd (10-11.30 a.m.).—Discussion: Encephalitis Lethargica. To be opened by Dr. EDWIN BRANWELL, followed by Dr. WILFRED HARRIS, Professor A. J. HALL, Dr. C. H. MELLAND. (11.30 a.m.-1 p.m.).—Discussion: Renal Efficiency Tests. To be opened by Professor H. McLEAN, followed by Professor BOYD. In the afternoons of Wednesday, Thursday and Friday, from 3 to 4.30, cases will be demonstrated by the honorary medical staff in the medical wards of the Royal Victoria Infirmary. Short papers and demonstrations will be arranged during the same hours.

Anyone wishing to take part in the above discussions, or give demonstrations, is asked to communicate with Dr. W. E. HUME, Honorary Secretary, Section of Medicine, 4, Ellison Place, Newcastle-on-Tyne, in order that he may forward a copy of the opener's remarks when available.

SURGERY.

President: Professor J. RUTHERFORD MORISON, D.C.L., LL.D., F.R.C.S.

Vice-Presidents: Professor H. BRUNTON ANGUS, F.R.C.S.; ARTHUR COOKE, F.R.C.S.; W. J. GREER, F.R.C.S.I.; A. M. MARTIN, M.B.

Honorary Secretaries: W. GIBLING BALL, F.R.C.S. (77, Wimpole Street, London, W.1); J. M. REXTON, F.R.C.S. (16, Sandyford Place, Glasgow, W.); G. GREY TURNER, M.S., F.R.C.S., F.A.C.S. (The Hawthorns, Osborne Road, Newcastle-on-Tyne).

The following programme has been arranged:

July 20th (10 a.m.).—Discussion: Acute Pleural Empyema. To be opened by Mr. HENRY WADE, C.M.G., D.S.O., M.D., F.R.C.S. (Edinburgh).

In the afternoon, at 3 o'clock, demonstrations will be given by Professor RUTHERFORD MORISON at the War Pensions Hospital of cases and specimens illustrating (1) Bipp, (2) Bone Cavities, (3) Bone Grafts. Cases will also be shown by other members of the staff.

July 21st (Morning Session).—Discussion: Compound Fracture of the Thigh and Leg.

In the afternoon, at 3 o'clock, demonstrations will be given at the Royal Victoria Infirmary of cases and specimens illustrating Compound Fracture of the Thigh and Leg.

July 22nd (Morning Session).—Discussion: The Diagnosis and Treatment of Injuries of the Intestines. To be opened by Mr. GORDON TAYLOR, O.B.E., M.S. (London).

In the afternoon, at 3 o'clock, demonstrations will be given by Mr. G. GREY TURNER at the Royal Victoria Infirmary of six cases of implantation of the ureter into the bowel.

Operations will be arranged by the staff of the Royal Victoria Infirmary for each afternoon at 2 o'clock.

One or two short papers will also be read on each day after the discussion.

Anyone wishing to take part in the discussions or demonstrations is invited to communicate with the Secretaries, and those wishing to read short papers are asked to send a summary, to be brought before the officers of the Section. There will also be an exhibition of specimens illustrating the subjects for discussion, and members are asked to advise the Secretaries of any specimens they propose to exhibit.

PATHOLOGY AND BACTERIOLOGY.

President: Professor STUART McDONALD, M.D., F.R.C.P. Ed.

Vice-Presidents: J. F. GASKELL, M.D., F.R.C.P.; JAMES A. MURRAY, M.D.; Professor MATTHEW J. STEWART, M.B., M.R.C.P.

Honorary Secretaries: R. R. ELWORTHY, O.B.E., M.D., M.R.C.P. (West London Hospital, Hammersmith, London, W.6); A. F. BERNARD SHAW, M.D., M.R.C.P.I. (Pathological Department, College of Medicine, Newcastle-on-Tyne).

Pathological Museum.

The Pathological Museum Committee proposes to arrange the material under the following heads: (1) Exhibits bearing on discussions and papers to the various Sections; (2) specimens and illustrations relating to any recent research work; (3) instruments relating to clinical diagnosis and pathological investigation; (4) individual specimens of special interest or a series illustrating some special subject. It is proposed to gather together a series of exhibits illustrating the pathology of individual cases. Such exhibits will include a brief clinical history of the case and mounted specimens of the different organs and tissues illustrating the pathological changes and the correlation of the lesions. Other interesting specimens will be welcomed. The Honorary Secretary of the Pathological Museum Committee is Dr. A. F. Bernard Shaw, Pathological Department, College of Medicine, Newcastle-upon-Tyne. The museum will occupy a central position in the same building as that in which the sectional work is carried on. Every care will be taken of specimens, and the contents of the museum will be insured. It is hoped to make arrangements for exhibitors to demonstrate their specimens.

PREVENTIVE MEDICINE WITH INDUSTRIAL DISEASES.

President: Sir THOMAS OLIVER, LL.D., M.D., F.R.C.P.

Vice-Presidents: Sir JOSIAH COURT, M.R.C.S.; T. EUSTACE HILL, O.B.E., M.B.; I. G. MODLIN, O.B.E., M.D.

Honorary Secretaries: C. M. WILSON, M.C., M.D. (64, South Audley Street, Grosvenor Square, W.1); W. H. DICKINSON, O.B.E., M.B., D.P.H. (1, Ridley Villas, Newcastle-on-Tyne).

ORTHOPAEDICS AND DISEASES IN CHILDREN.

President: A. H. TUBBY, C.B., C.M.G., M.S., F.R.C.S.

Vice-Presidents: R. C. ELMSLIE, O.B.E., M.S., F.R.C.S.; H. MORLEY FLETCHER, M.D., F.R.C.P.; JACHLAN G. FRASER, M.D.; Sir HENRY M. W. GRAY, K.B.E., C.B., C.M.G., F.R.C.S.; A. E. MORISON, F.R.C.S. Edin. (Director of Demonstrations).
Honorary Secretaries: C. MAX PAGE, D.S.O., F.R.C.S. (134, Harley Street, London, W.1); FRANK HAWTHORN, D.S.O., M.D. (10, Ellison Place, Newcastle-on-Tyne); H. R. SOUTER, M.D. (Ministry of Pensions Hospital, Castle Leazes, Newcastle-on-Tyne).

The following preliminary programme has been arranged:

July 20th (10 a.m.).—Chairman: Mr. A. H. Tubby. Discussion: The Early Diagnosis and Treatment of Anterior Poliomyelitis.

July 21st (10 a.m.).—Chairman: Dr. H. Morley Fletcher. Discussion: Blood Diseases in Children.

July 22nd (10 a.m.).—Chairman: Sir Henry M. W. Gray. Discussion: Tuberculosis of Bone; General Principles of Treatment.

The following Sections meet on two days—Wednesday and Thursday, July 20 and 21.

NEUROLOGY AND PSYCHIATRY.

President: Professor A. W. MACKINTOSH, M.D., F.R.C.P. Ed.

Vice-Presidents: A. HELEN A. BOYLE, M.D.; E. FARQUHAR BUZZARD, M.D., F.R.C.P.; HARRY CAMPBELL, M.D., F.R.C.P.; HORSLEY DRUMMOND, M.D.

Honorary Secretaries: ANTHONY FEILING, M.D. (41, Devonshire Street, London, W.); GEORGE HALL, C.M.G., M.D., M.R.C.P. (1, Eslington Road, Jesmond Road, Newcastle-on-Tyne).

The following provisional programme has been arranged:

July 20th (10 a.m.).—Discussion: The Diagnosis and Treatment of Borderland Cases. To be opened by Professor G. M. ROBERTSON (Edinburgh) and Dr. JAMES COLLIER (London).

July 21st (10 a.m.).—Papers.

OPHTHALMOLOGY.

President: Professor J. D. WARDALE, M.B., B.S.

Vice-Presidents: H. P. BENNETT, M.B.; Lieut.-Colonel R. H. ELLIOT, M.D., F.R.C.S., I.M.S. (ret.); HARRY M. TRAQUAIR, M.D., F.R.C.S. Ed.

Honorary Secretaries: N. B. B. FLEMING, M.B., Ch.B. (9, Harley Street, London, W.1); STANLEY ROBSON, M.S., F.R.C.S. Ed. (Milton House, Rowlands Gill, co. Durham).

The following provisional programme has been arranged:

July 20th (10 a.m.).—Discussion: The Causes and Prevention of Blindness. To be opened by Mr. BISHOP HARMAN, F.R.C.S. (London).

July 21st (10 a.m.).—Discussion: The Treatment of Corneal Ulcers. To be opened by Mr. J. V. PATERSON, F.R.C.S. Edin. (Edinburgh).

OTO-RHINO-LARYNGOLOGY.

President: G. WILLIAM HILL, M.D., B.Sc.

Vice-Presidents: R. GORDON BELL, M.D., F.R.C.S. Edin.; JAMES DON, M.D.; DAN MCKENZIE, M.D., F.R.C.S. Edin.

Honorary Secretaries: LIONEL COLLEDGE, M.D., F.R.C.S. (22, Queen Anne Street, London, W.1); W. FRANK WILSON, M.B., B.S. (97, Jesmond Road, Newcastle-upon-Tyne).

The following provisional programme has been arranged:

July 20th (10 a.m.).—Discussion: In connexion with the Early Diagnosis and Treatment of Otitis Media occurring in Aural Cases. To be opened by Sir CHARLES BALLANCE, K.C.M.G., C.B.

July 21st (10 a.m.).—Discussion: The Various Problems presented by Haemorrhage occurring in connexion with Operations on the Tonsils.

PHYSIOLOGY, PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

President: H. H. DALE, C.B.E., M.D., F.R.S.

Vice-Presidents: Professor A. V. HILL, M.A., D.Sc., F.R.S.; Professor JOHN C. MEARNS, M.D.; Professor J. A. MENZIES, M.D.; ALFRED PARKIN, M.D., M.R.C.P.

Honorary Secretaries: O. INCHLEY, M.A., M.D. (Babraham, Cambridge); Miss MILDRED ATKINSON, B.Sc. (College of Medicine, Newcastle-on-Tyne).

VENEREAL DISEASES.

President: Colonel L. W. HARRISON, D.S.O., R.A.M.C.

Vice-Presidents: JAMES CHARLES BUCKLEY, M.D.; CHARLES GIBBS, F.R.C.S.; MARY RAW, M.B.

Honorary Secretaries: KENNETH M. WALKER, O.B.E., F.R.C.S. (86, Harley Street, London, W.1); JAMES HUDSON, M.D. (42, Crossley Terrace, Newcastle-on-Tyne).

The following provisional programme has been arranged:

July 20th (10 a.m.).—Treatment of Syphilis in Men, by Dr. R. MacKenzie. Syphilis in Women and Children, by Professor Walter Swayne.

July 21st (10 a.m.).—Treatment of Gonorrhoea in Men, by Dr. David Lees. The Standard of Cure in Gonorrhoea, by Dr. Townley Clarkson.

In the afternoon of Wednesday (July 20th) a demonstration will be held of Methods of Diagnosis and Treatment in Venereal Diseases, Dark-ground Illumination Work, Models of Venereal Disease Clinics, etc.

The following Section meets on two days—Thursday and Friday, July 21 and 22.

OBSTETRICS AND GYNAECOLOGY.

President: Professor R. P. RANKEN LYLE, M.D.
Vice-Presidents: Lady BARRETT, M.D.; W. R. GROVE, M.D.; WILLIAM ROBINSON, F.R.C.S.
Honorary Secretaries: GORDON LEY, F.R.C.S. (5, Wimpole Street, London, W.1); MABEL R. CAMPBELL, M.A., M.B. (49, Wingrove Road, Newcastle-on-Tyne); E. FARQUHAR MURRAY, M.D., F.R.C.S. (52, Jesmond Road, Newcastle-on-Tyne).

The following provisional programme has been arranged:
July 21st (10 a.m.).—Discussion: The Role of Caesarean Section in Midwifery. To be opened by Dr. EARDLEY L. HOLLAND (London) and Dr. J. M. MURDO KERR (Glasgow). Paper: The

DONALD (Manchester) and Dr. FARQUHAR RIZZARD (London). Papers to be followed by discussion: (1) Curettage, (a) Diagnostic, (b) Treatment of Uterine Haemorrhage, by Dr. H. BECKWITH WHITEHOUSE (Birmingham). (2) The Position of the Medical Practitioner called in to attend a case of Procured Abortion, by Dr. JOHN CAMPBELL (Belfast).

The following Sections meet on one day as indicated.

Wednesday, July 20th.

AMBULANCE AND RED CROSS.

President: Sir JAMES CANTLIE, K.B.E., F.R.C.S.
Vice-Presidents: ROBERT ANDERSON, M.D.; Sir G. T. BEATSON, K.C.B., K.B.E., M.D.; Major-General Sir G. H. EVATT, K.C.B., M.D.; Rev. C. F. TOWNSLEY, M.A.
Honorary Secretaries: Lieut.-Colonel R. M. VICK, O.B.E., F.R.C.S. (The Warden's House, St. Bartholomew's Hospital, E.C.1); H. L. RUTTER, M.B.E., F.R.C.S. (51, West Parade, Newcastle-on-Tyne).

PROCTOLOGY.

President: J. P. LOCKHART-MUMMERY, F.R.C.S.
Vice-Presidents: HENRY B. DRNSHAM, M.B.; W. ERNEST MILLS, F.R.C.S.; D. P. D. WILKIE, O.B.E., F.R.C.S.
Honorary Secretaries: CECIL W. ROWNTREE, F.R.C.S. (9, Upper Brook Street, London, W.1); HAMILTON DRUMMOND, F.R.C.S. Edin. (6, Saville Place, Newcastle-on-Tyne).

Thursday, July 21st.

DERMATOLOGY.

President: JOHN FARQUHAR CHRISTIE, M.A., M.B.
Vice-Presidents: ERNEST DORE, M.D., F.R.C.P.; ARTHUR D. HEATH, M.D., M.R.C.P.; D. WELLS PATTERSON, O.B.E., M.D., M.R.C.P.
Honorary Secretaries: WILLIAM JENKINS OLIVER, M.A., M.B. (53, Queen Anne Street, London, W.1); SYDNEY THOMSON, M.B., B.S. (19, Windsor Terrace, Newcastle-on-Tyne).

The following provisional programme has been arranged:
July 21st (10 a.m.).—Discussions: (1) Cutaneous Sensitization and Focal Sepsis in the Etiology of certain Skin Affections. To be opened by H. W. BAIBER, M.B. Camb., M.R.C.P. (2) The Association of Skin Tuberculosis with Visceral and other Tuberculous Manifestations. To be opened by GEORGE H. LANCASHIRE, M.D. (3) Dermatological Cases attending the Pensions Boards. To be opened by HENRY MACCORMAC, C.B.E., M.D. Edin., F.R.C.P. Lond. (with the permission of the Ministry of Pensions).

Friday, July 22nd.

MEDICAL SOCIOLOGY.

President: Sir JENNER VERRALL, LL.D., M.R.C.S.
Vice-Presidents: CHARLES BUTTAR, M.A., M.D.; A. C. FARQUHARSON, M.D., M.P.; E. ROWLAND FOTHERGILL, M.B., B.S.
Honorary Secretaries: J. F. WALKER, M.B. (Rocklands, Clifton Terrace, Southend-on-Sea); MABEL G. BRODIE, M.B. (Maternity and Child Welfare Offices, 42, Old Elvet, Durham).

RADIOLOGY AND ELECTRO-THERAPEUTICS.

President: ROBERT KNOX, M.D.
Vice-Presidents: W. HOPE FOWLER, F.R.C.S. Edin.; ROBERT EDWARD HOWELL, M.B., C.M.
Honorary Secretaries: JAMES METCALFE, M.D. (123, Harley Street, London, W.1); THOMAS LOWE BUNTING, M.D. (6, Portland Terrace, Newcastle-on-Tyne).

The following provisional programme has been arranged:
July 22nd (10 a.m.).—Discussion: On the Changes induced in Blood Constituents by Radiations: (a) Experimental evidence, Professor SIDNEY KISS and Dr. ARCHIBALD LEITCH; (b) Clinical observations, Dr. MOTTRAM, Dr. GAMLEN, Dr. J. B. WATERS, Dr. METCALFE, Dr. HOPE FOWLER and others. On Morbid Conditions of the Blood: (1) The Anaemias, (2) Leukæmia, (3) Banti's disease, etc. Opening paper by Professor G. L. GYLAND, C.M.G. (Edinburgh). Discussion on

Surgical Diathermy, to be opened by Dr. CUMBERBATCH, followed by Dr. HOWARD HUMPHRIES, Dr. SABERTON and others. Exhibition of radiograms, etc., in the afternoon.
A visit will be paid to the x-ray and treatments of the Royal Victoria Infirmary.

UROLOGY.

President: J. W. THOMSON WALKER, O.B.E., F.R.C.S.
Vice-Presidents: P. J. CAMMIDGE, M.D.; JOHN CLAY, C.B.E., F.R.C.S.; H. C. PEARSON, F.R.C.S. Ed.
Honorary Secretaries: SYDNEY G. MACDONALD, F.R.C.S. (51, Queen Anne Street, London, W.1); W. S. DICKIE, O.B.E., F.R.C.S. (Ardencaple, Southfield Road, Middlesbrough).

The following provisional programme has been arranged:
July 22nd (10 a.m.).—Discussion: The Diagnosis and Treatment of Cystitis. To be opened by J. P. DOBSON, M.S., F.R.C.S. (Surgical). Papers: Experimental Evidence bearing on the Source of the Amyolytic Ferment in the Urine, by P. J. CAMMIDGE, M.D.; Open Prostatectomy, by J. W. Thomson Walker, M.B., F.R.C.S.; Treatment of Bladder Growths, by Sydney G. MacDonald, M.B., F.R.C.S.

The Honorary Local General Secretary of the meeting is R. J. WILLAN, M.V.O., O.B.E., F.R.C.S., 6, Kensington Terrace, Newcastle-on-Tyne.

PROVISIONAL TIME TABLE.

The following is the provisional time table for the Newcastle-upon Tyne Meeting, 1921:

FRIDAY, JULY 15TH, 1921.

10 a.m.—Annual Representative Meeting.

SATURDAY, JULY 16TH.

9.30 a.m.—Representative Meeting.

MONDAY, JULY 18TH.

9.30 a.m.—Council Meeting.

10 a.m.—Representative Meeting.

TUESDAY, JULY 19TH.

9.30 a.m.—Representative Meeting.

2 p.m.—Annual General Meeting.

5 p.m.—Religious Services.

8 p.m.—Adjourned General Meeting, President's Address.

WEDNESDAY, JULY 20TH.

9 a.m.—Council Meeting.

6.30 p.m.—Secretaries' Dinner.

8 p.m.—Special Address on Industrial Medicine.

THURSDAY, JULY 21ST.

10 a.m. to 1 p.m.—Sectional Meetings.

3 to 4.30 p.m.—Demonstrations.

7.30 p.m.—Annual Dinner.

FRIDAY, JULY 22ND.

10 a.m. to 1 p.m.—Sectional Meetings.

3 to 4.30 p.m.—Demonstrations.

7.30 p.m.—Popular Lecture.

SATURDAY, JULY 23RD.

Excursions.

ACCOMMODATION AT NEWCASTLE.

Hotels.

A list of these was published in the SUPPLEMENT of May 7th. The Market, Clyde, and Norfolk are strictly commercial hotels. Doctors bringing their wives with them are advised to apply to the hotels heading the list, unless applying to the residential hotels for accommodation. It is suggested that two members attending the Annual Meeting might arrange to engage a room with two beds if they fail to obtain single rooms. The managers of the hotels have been informed that, in the event of one of the beds in the rooms with twin-beds being engaged by a member, the remaining bed must only be occupied by a member of the British Medical Association.

Members are again advised to make early application for rooms at Whitley Bay.

Lodgings.

The list of these is a small one. The scarcity of houses has driven many people into lodgings; thus a very large number were found when visited to be in permanent occupation. The landladies, too, showed an independence

which was somewhat trying. The committee therefore wishes to make the fullest use of hotel accommodation. A list of lodgings, however, is available, but it was felt that it would save much annoyance and correspondence if members desiring to stay in lodgings would communicate direct with the Honorary Secretary of the Hotels and Lodgings Committee, Dr. E. Farquhar Murray, 52, Jesmond Road, Newcastle-upon-Tyne, who will arrange for their accommodation.

The following points, if observed, will facilitate the work of allocation when application is made:

1. Engaging rooms for a week will be much easier than for a night or two. The majority of landladies want this, although a number state terms for a night.
2. The charges for bed and breakfast range from 6s. to 12s. 6d. The range, therefore, should be stated.
3. The number for whom accommodation is required should be stated, and whether medical men, medical women, or doctor and wife.
4. The majority of the landladies offer only bed and breakfast. It should be stated if more meals are required.
5. The exact dates of arrival and departure should be given.
6. When writing state if, failing accommodation being found in lodgings, the member would be agreeable to being put up in an hotel, hostel, or elsewhere.

Hostels.

Particulars of one Newcastle hostel were given in the SUPPLEMENT of May 7th. A number of the Durham hostels and colleges have been put at the disposal of the Association, but it has been decided not to take them over at present until an indication is given that a sufficient number of members wish to stay at Durham, or until the accommodation at Newcastle is fully taken up. Members who desire to reside at Durham during the meeting should write to the Local Representative, Dr. F. F. T. Hare, The Avenue, Durham, as early as possible, when the necessary accommodation will be provided.

Medical Women.

Those who propose to come to the meeting and have any difficulty in finding accommodation are requested to communicate with Dr. Ethel Williams, 3, Osborne Terrace, Newcastle-on-Tyne, who is Chairman of the Lady Doctors' Subcommittee.

General Information.

The Honorary Secretary, Dr. E. F. Murray, will gladly give any information about accommodation to members who apply to him. No anxiety need be felt on the question of securing accommodation if members will only make arrangements in good time. There are abundant tea-rooms and restaurants in the town, and a list of these will be published before the meeting.

Association Notices.

REPRESENTATIVE MEETING.

DATE.

THE Annual Representative Meeting at Newcastle will begin on Friday, July 15th, 1921, at 10.0 a.m.

NOTICES OF MOTION AND AMENDMENT BY DIVISIONS AND BRANCHES.

The Supplementary Report of Council to the Representative Meeting will appear in the SUPPLEMENT of July 2nd, 1921.

Notices of Motion and Amendment by Divisions and Branches for consideration by the Annual Representative Meeting will be published in the SUPPLEMENT as they are received, but none can be published later than July 2nd, for which purpose they must be received by the Medical Secretary not later than the first post on Monday, June 27th.

It will be possible, however, to include in the Agenda for the Annual Representative Meeting all Notices of Motion and Amendment which are received by the Medical Secretary *not later than the first post on Monday, July 4th, 1921.*

ELECTION OF 24 MEMBERS OF COUNCIL BY BRANCHES IN UNITED KINGDOM.

The following is a list of the nominations received:

Group.	Branches in Group.	Candidates nominated.	No. of Seats.
A	North of England. North Lancashire and South Westmorland	Dr. JAMES DON (Newcastle-on-Tyne)	1
B	Yorkshire	Dr. A. FORBES (Sheffield)	1
C	Lancashire and Cheshire	Dr. T. W. H. GARSTANG (Altrincham) Mr. F. STRONG HEANEY (Liverpool) Dr. FRANK RADCLIFFE (Oldham)	2
D	East York and North Lincoln. Midland	Maj.-Gen. Sir R. H. LUCE, K.C.M.G., C.B. (Derby)	1
E	Cambridge and Hunt- ington. Essex. Norfolk. South Mid- land. Suffolk.	Dr. L. O. TURNER (Great Missenden)	1
F	Birmingham Staffordshire	Dr. H. C. MACTIER, M.B.E. (Wolver- hampton) Dr. A. W. NUTHALL (Birmingham)	1
G	North Wales. Shrop- shire and Mid Wales. South Wales and Mon- mouthshire	Dr. W. B. CRAWFORD TREASURE (Cardiff)	1
H	Metropolitan Counties	Dr. H. S. BEADLES (West Ham) Dr. C. BUTTAR (Kensington) Lord DAWSON OF PENN. G.C.V.O., K.C.M.G. (Marylebone) Mr. N. BISHOP HAMMAN (Marylebone) Dr. R. LANGDON DOWN (Hampton Wick) Dr. Wm. PATTERSON (Willesden)	4
I	Bath and Bristol Gloucestershire West Somerset Worcestershire and Herefordshire	Dr. H. C. BRISTOWE (Wroughton) Dr. A. O. HOLBECH (Worcester)	1
J	Dorset and West Hants. South-West- ern. Wiltshire	Mr. RUSSELL COOMBE (Exeter)	1
K	Oxford and Reading. Southern	Dr. D. A. SHEAHAN (Portsmouth)	1
L	Kent. Surrey. Sussex	Dr. J. ROWLAND FOTHERGILL (Hove) Dr. ARNOLD LYNDON (Hindhead)	1
M	Aberdeen. Dundee. Northern Counties. Perth	Dr. DAVID LAWSON (Banchory)	1
N	Edinburgh. Fife	Dr. JOHN STEVENS (Edinburgh)	1
O	Glasgow and West of Scotland (4 City Divisions)	Dr. Wm. SNODGRASS (Glasgow)	1
P	Border Counties. Glas- gow and West of Scotland (5 County Divisions). Stirling	Dr. HUGH MILLER (Hamilton)	1
Q	Connaught. South- Eastern of Ireland	Dr. DENIS WALSH (Graigie, Kilkenny)	1
R	Leinster	Dr. R. C. PEACOCKE (Blackrock, Dublin)	1
S	Munster	Dr. PHILIP G. LEE (Cork)	1
T	Ulster	Mr. R. J. JOHNSTONE (Belfast)	1
			24

Voting papers for Groups C, F, H, I, and L will be posted from Head Office on Saturday, May 21st; they are returnable by Monday, June 6th, first post.

NOTICES OF MOTION BY DIVISIONS FOR THE ANNUAL REPRESENTATIVE MEETING, NEWCASTLE, 1921.

By BUCKINGHAMSHIRE DIVISION:

That reports of Division meetings should be published in full in the BRITISH MEDICAL JOURNAL SUPPLEMENT.

That this meeting approves of the idea of federation with other medical bodies, provided that the greatest care is taken to safeguard the interests of

the British Medical Association, especially with regard to its financial interests and medical policy.

That non medical bodies should be excluded from a federation.

By Mr. McADAM ECCLES (Marylebone):

That the draft scheme prepared by the Metropolitan Counties Branch Council of an organization for London of a national provident scheme for hospital and additional medical services be approved by the Representative Body as conforming to the policy of the Association in regard to voluntary hospitals

[NOTE.—This scheme was published in the SUPPLEMENT, April 30th, 1921, pp 161-162]

Meetings of Branches and Divisions.

SUSSEX BRANCH CHICHESTER AND WORTHING DIVISION

A MEETING of this Division was held at Chichester on April 27th, when Dr David Ewart was in the chair. At the conclusion of the business agenda an interesting address was given by Dr Robert Hutchison, physician to the London Hospital on "The Diagnostic Significance of Abdominal Pain in the Adult." Many members took part in the ensuing discussion, and Dr Hutchison replied. The meeting passed a cordial vote of thanks to the lecturer for his instructive address. Dr Hutchison subsequently dined with the members, and a pleasant evening was spent. This is the third of a series of similar meetings held during this divisional year, and the practice of combining the pursuit of medical science with the cultivation of the social qualities has been a success.

MEETINGS TO BE HELD.

BIRMINGHAM BRANCH CENTRAL DIVISION—The annual meeting of the Central Division will be held at 18 Bennett's Hill, on Thursday, June 16th, at 3.45 p.m. Agenda: To instruct Representatives. To elect officers for ensuing year. Nominations for officers must be in the hands of the Honorary Secretaries fourteen days before the meeting. Members are requested to bring with them copies of the SUPPLEMENT of April 30th.

METROPOLITAN COUNTIES BRANCH—The annual general meeting of the Metropolitan Counties Branch will be held at 429 Strand, W.C., on Friday, June 24th at 4 p.m. Business: (1) Report of scrutineers as to the election of new officers (2) Annual Report of Council (3) Alteration in Rule 11 by the insertion of words providing that such members of the Branch as are members of the Central Council shall be ex officio members of the Metropolitan Counties Branch Council (4) President's address by Dr H. B. Brackenbury, The Psychologist in Public Life.

METROPOLITAN COUNTIES BRANCH CITY DIVISION—The annual general meeting of the City Division will be held at the Metropolitan Hospital on Friday, May 27th at 9 p.m. Agenda: (1) Election of officers and Representatives for ensuing year (2) Instructions to Representatives (3) 10 p.m. Address by Dr H. B. Brackenbury, Vice President of Branch and President elect of Branch. Dr Brackenbury will explain the National Provident Scheme for hospital and additional medical services. As this is likely to affect the general practitioner very closely, it is hoped that everyone will make a special effort to be present. It is particularly to be desired that as many members as possible who are resident in the Islington section shall attend. It is proposed during the next session to hold several of the meetings, both clinical and ordinary, in the Islington area. During the session 1921-22 there will be a dinner entertainment (on November 3rd) and three dinner dances. Monthly lectures will be given, the first, in October, being a dental lecture, with lantern slides, by Dr C. E. Wallis.

METROPOLITAN COUNTIES BRANCH LEWISHAM DIVISION—A meeting of the Division will be held on Tuesday, May 24th at 8.30 p.m., at St George's Lodge, Catford, S.E.6. Agenda: Discussion of the provident scheme for hospitals in London area. Any other business.

MIDLAND BRANCH KESTIVEN DIVISION—The annual meeting of the Division will be held at Dr T. P. Greenwood's residence, 36 St. Mary's Street, Stamford, on Tuesday, May 31st, at 3.30 p.m. Business: (1) To elect the Chairman and Committee for the ensuing year (2) To elect a Representative in Representative Body. For the purpose of this election, this meeting is a joint meeting of the Kesteven and Holland Divisions. (3) To discuss the Meeting, and to instruct honorary secretary, Dr. He has obtained authority out the Division, for called in by the police. Tea will be provided at hoped that objects of interest in Stamford may be viewed.

SOUTH WESTERN BRANCH EXETER DIVISION—The annual meeting of the Division will be held in the library of the Royal Devon and Exeter Hospital, on Thursday, May 26th, at 3 p.m. Tea will be provided. Agenda: Report of Executive Committee. Election of officers and representatives. Consider Annual Report of Council.

WORKSHIRE BRANCH SHEFFIELD DIVISION—The annual meeting of the Division will be held at the Church House, St. James Street, Sheffield, on Friday, May 27th, at 8.30 p.m., when the report of the Executive Committee will be presented and the officers and committee elected for the ensuing year.

SCOTTISH CONSULTATIVE COUNCIL'S REPORT.

VIEWS OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

THE Royal College of Physicians of Edinburgh at its last quarterly meeting adopted the following report of a Committee of the College regarding the Interim Report submitted by the Consultative Council on Medical and Allied Services to the Scottish Board of Health.

In reviewing the Interim Report of the Consultative Council on Medical and Allied Services the Committee of the College have kept in view the terms of the reference from the Board of Health to the Consultative Council, as follows:

'To consider and to make recommendations as to the systematic provision of such form of medical and allied services as should, in the opinion of the Council, be available for the community.'

The reference raises two issues which, although closely related, may with advantage be considered separately—namely (1) What forms of medical and allied services should be available for the community? (2) How best can the provision of such services be systematized?

(1) What forms of medical and allied services should be available for the community? The Committee of the College are in accord with the view of the Consultative Council that the present provision of such services throughout the community is inadequate and patchy. Difficulties and irregularities exist which call for careful consideration.

The Committee note with satisfaction the definite recognition of the home and the household as the primary centre of medical care. From the medical as well as from the social point of view the family is the normal unit. If the health of the nation is to be placed on a high level, the home must be the centre of medical endeavour, both preventive and curative. The family doctor, in immediate relation with the individual household, must be the instrument and agent of any scheme for the systematized provision of medical and allied services. Households should be encouraged to look to the family doctor as their normal medical adviser and guardian, to whom they naturally refer all matters pertaining to health, and who personally renders such services as he can, and likewise sees that auxiliary services otherwise provided are suitable and sufficiently brought within their reach.

It is, in the opinion of the Committee of the College, a primary and essential condition in the provision of extra medical services that the family doctor should be the medium of communication and arrangement in the case of households which are normally under his care. Only in this way can the continuous attention of the doctor to the well being of the household be maintained and the interest of the community secured. Divorced from the family doctor as the ultimate health agent, attempts at the systematic provision of medical services are, in the judgement of the Committee, doomed to failure.

If the premiss be conceded the way is clear to a useful consideration of the directions in which the efforts of the individual doctor may properly be supplemented by extra services duly systematized.

Provision for such extra services has already been made in certain directions, but in piecemeal and unequal fashion. In connexion with some of these it may fairly be questioned if sufficient care has been taken to secure the friendly concurrence and co-operation of the family doctor in the way which seems to the Committee essential for success. Obvious examples of the lack of proper co-ordination are to be found in connexion with the education medical services and child welfare and maternity schemes.

Such agencies affect the life of family life and their operation can only be successful when intimately linked with those of the family adviser. It is most desirable that any machinery for the betterment of the community erected outside the individual home should be brought into intimate relationship with the operation of the doctor within the home. The doctor should be a party to all communications and measures proposed in the interest of the members of the household. No one knows better than the family doctor the lacunae which exist in his

an armamentarium for the suitable treatment of various patients at varying stages of illness; nor will anyone be more appreciative of sound proposals whereby the deficiencies can be made good.

The Committee of the College are unanimously of opinion that the facilities presently available for the care and treatment of sick persons throughout the country call for improvement and expansion in numerous directions. They recognize that existing needs differ somewhat in different parts of the country. The needs of a densely populated centre of industrial life are different from those of a scattered rural area. In this respect the needs of the Highlands and Islands call for particular consideration.

The recommendations of the Consultative Council are evidently based on a careful review of the available evidence. The Committee of the College have gone over the recommendations in detail and are generally in agreement with the proposals, provided that the relation of the family doctor to the extra medical services be safeguarded, and that certain conditions as to the mode of provision and systematization of such services be fulfilled.

The Committee of the College desire to reinforce the position that a great improvement might be effected in relation to the immediate treatment of illness and to the prevention of disease by a thoroughgoing reform of housing conditions, and particularly by the education of the inmates as to how to make the best use of the dwelling house.

The Committee approve of the recommendation of the Council that certain services involving special skill or equipment, which are essential for successful medical treatment, and are at present beyond the reach of certain classes of the community, should be made available to all. In this sense the Committee approve of the suggested provision of special accommodation for cases of illness, either acute or chronic, which, while not requiring special surgical or other skill, cannot in the judgement of the doctor be adequately treated in the patient's own home. This arrangement would have the added advantage of facilitating the work of sick nursing.

While really serious surgical cases would for the most part continue to be sent for operation to hospitals or homes, it seems right that supplementary professional advice and assistance should be made available to doctors in connexion with graver cases of illness occurring in their practice and continuing under their care. Some scheme for the simplification and facilitation of medical and surgical consultation throughout the country is most desirable. It seems unnecessary at this stage to enter into detailed consideration of the proposed plan. In the opinion of the Committee this may safely be left to gradual development along natural lines, according to the needs and possibilities of the several areas.

The Committee are in hearty agreement with the Council's recommendation in favour of the provision of adequate laboratory facilities, and especially the bringing of these more uniformly within easy reach of practitioners throughout the country. It seems natural that in some areas such facilities might be associated with local clinics. Here also the detailed scheme outlined in the report must evidently be a matter of gradual development.

The Committee are unanimously in favour of the extension of the principle of convalescent homes in connexion with the hospitals of the country. This would notably ease the strain on hospital accommodation, and obviate the many disadvantages presently attaching to the system of waiting lists, which seriously limit the value of the larger hospitals. Apart from the needs of hospitals, it would be an immense boon to the general practitioner to have more closely at his service convalescent homes for the behoof of persons recovering from serious illness involving long convalescence. Much may be said likewise for the provision of country rest homes to which persons suffering from the strain of work, or other cause, might be sent with a view to anticipate illness or prevent more serious breakdown.

No argument is needed to enforce the value to the patient and to the doctor as to the extension of the methods of district nursing. The Queen Victoria Jubilee Nurses' Organization has brought incalculable benefit to the community, and the voice of the profession is unanimous in pressing for a still larger development along such lines. What the rich can afford for themselves in this direction should be made available to all. No greater immediate service could be rendered to the country by the Board of Health than the placing of the Queen Victoria Jubilee Organization on a larger and more stable basis. The proposal for an elaborate service of health visitors, apart from such nurses, is little favoured by the Committee. The experience of a good many members of the Committee

is strongly adverse to the methods of this service as hitherto developed. The Committee are unanimously of opinion that health visitors should in all cases have enjoyed nursing training.

With regard to maternity, the Committee favour the view that provision must be made whereby skilled medical guidance is available for every expectant mother. For the most part this should be attained by way of the family doctor, who in many directions may be the means of ensuring safe gestation and anticipating trouble. The doctor would be suitably aided by a service of midwives who may frequently, in cases of normal labour, replace the doctor. In view of the occurrence of difficult cases, or where the home is obviously unsuitable, it is desirable that a sufficient number of maternity beds should be available in every district.

The Committee concur in the Council's recommendation that adequate facilities should exist throughout the country for conservative dentistry.

(2) Assuming that an expansion of medical and allied services such as has been outlined should be afforded, a further question arises as to the method whereby the services should be made available. How best can the provision of such services be systematized? The Committee would remind the College that the Board of Health, as now constituted, represents the centre of co-ordination for purposes of direction and administration of all the public services and agencies concerned with the health of the community.

The College has on various occasions urged the desirability of a complete and systematized centralization of health activities. The Consultative Council on Medical and Allied Services, whose interim report is now under consideration, is an important auxiliary of the Board. The College gave its concurrence to the constitution of the Council by recommending certain persons for inclusion in its membership.

Whatever conclusions the Board of Health may come to after consideration of the views of the Consultative Council, and of other bodies who may volunteer suggestions as to the policy to be followed in the interest of the health of the community, it is obvious that a successful issue will chiefly depend on the just adaptation and smooth running of the machinery whereby the policy is put into practice throughout the country.

If such co-ordination of services and agencies be essential at the centre, similar co-ordination is no less necessary throughout the country, and particularly at the periphery. The Committee of the College cordially endorse the plea of the Consultative Council in pressing for a unification of the various local authorities concerned with health and treatment in each district. Such unification is the first step towards a successful systematization of medical services.

Locally as well as centrally the various agencies concerned with the direction and maintenance of health services must be closely linked up. The question whether this should be effected by enlargement of the presently existing Health Committees of local authorities so as to include in their membership a larger proportion of competent persons—by reason of training and experience—or by the creation of a special local authority—erected *ad hoc*—hardly rises for consideration here. The Committee would, however, emphasize the opinion that ultimately the success of the Board of Health's policy will largely depend on the extent to which the policy embodies the principle that the health service of the nation, however elaborated, should be based on the family doctor as the medical attendant and guardian of the household, and that, whatever extra services are provided, should be conceived as supplemental and auxiliary to his efforts.

In endorsing the above recommendations made by the Consultative Council the Committee of the College would not have it supposed that they look for the immediate realization of the details outlined in the scheme of medical services proposed in the report. The present economic condition of the country makes this manifestly impossible. It is, in their opinion, none the less important that a beginning be made and sound foundations laid for the gradual development later as circumstances may permit.

Lastly, in relation to financial considerations which hardly come within the terms of the reference, it seems pretty clear to the Committee that, while the wealthier classes can already attain most of the advantages which are now claimed for all, it will be found that for a certain section of the community, fairly described as necessitous, the provision of all medical service will have to be made at the public expense. It seems no less clear that the costs of medical services as expanded in the way that has been outlined—which will be necessarily considerable—

might, for a large intermediate group between the wealthy and the necessitous, be met by a scheme of graded contribution either voluntary or enforced by statute.

The Committee think it proper to add that some members of the Committee, in adhering to the Committee's report, object to an extension of medical benefits under the National Health Insurance Acts to dependants of the insured population except on a basis of voluntary contribution, while some desire to place on record their continued disapproval of the conditions of service under the medical benefit section of the National Health Insurance Acts.

Correspondence.

A Medical Service Scheme for Scotland

SIR,—On January 25th last the Medical Guild addressed a letter to the medical profession in Scotland with an accompanying memorandum, both of which adversely criticized the Interim Report on a Scheme of Medical Service for Scotland presented to the Scottish Board of Health by the Consultative Council on Medical and Allied Services. These communications were published in the *Scotsman* on the following day. The "Summary of Recommendations" taken verbatim from the interim report was annexed to the letter.

The letter contained the following questions to which answers were invited: (1) Do you approve of the terms of this letter and memorandum? (2) Do you approve of the proposed extension of National Health Insurance (Recommendation 4)?

We are now in a position to announce the result of this referendum, which is of equal importance to the general public and the medical profession. Question 1 referred to the letter and memorandum of the Guild, whose attitude is expressed in the memorandum thus: "Matters will be righted only when the State ceases to interfere with medical attendance on sick people other than those who belong to the necessitous classes, so long as the sick are not a danger to the community by reason of infectivity." Question 2 requires no elaboration. Replies favourable to the policy of the Guild required "Yes" for Question 1 and "No" for Question 2.

The returns so far to hand number 1,331. Of that number, 1,105, or approximately 83 per cent., voted "Yes" to Question 1 and "No" to Question 2, 165, or approximately 12 per cent., answered both questions in the negative, the remaining 61, less than 5 per cent., voted "No" for Question 1 and "Yes" for Question 2, and thus this small minority only were in favour of the recommendations of the Consultative Council. The large majority, 1,270 (that is, 1,105 plus 165), over 95 per cent. of the total vote, were therefore opposed to further extension of the National Health Insurance Act, which is made the basis of the Consultative Council's scheme. In many cases replies were accompanied by emphatic protests against the nationalization of the practice of medicine, notably from men who have had ample experience of work under a State Medical Service similar in outline to the scheme proposed by the Consultative Council.

It is difficult to give an accurate statement of the number of men at present serving under the National Insurance Act who voted with the above large majority, but the returns received from certain working class districts prove that the proportion was large.

The result of this referendum demonstrates that a large section of the profession in Scotland is opposed to the provision for medical services recommended in the interim report, including the extension of the National Health Insurance Act.

It will be remembered that the Consultative Council consider co-operation of the medical profession to be essential for the success of this scheme. The above results clearly indicate that this will not be obtained. On the contrary, it is evident that the profession would support a medical service limited to those who are unable to make provision for themselves. This would restrict the large and increasing national expenditure on medical practice, and would in no way interfere with the national health.—We are, etc.,

FRANCIS M. CAIRD,

President.

FRIDRICK POPEP,

Honorary Secretary.

The Medical Guild Edinburgh,
May 12th

Insurance Remuneration.

SIR,—I notice in the address delivered by Dr. Alfred Cox to the Leeds Division of the British Medical Association he alluded to the possibility of a demand being made in

the near future for a reduction of the National Insurance capitation fee to the doctors.

Now, Sir, I for one consider that such a demand would be preposterous, and I am quite sure that the great majority of panel practitioners would be of my way of thinking. Why should such a demand be made? We have only had the increased fee for fifteen months, while many other workers have had a rise for years, and not one rise only. What does our rise amount to? The fee was increased from 7s. to 11s.—just 57 per cent.—while the increase in some workers' wages was over 200 per cent. It will be time enough to talk of reduction when the cost of living is reduced to about 60 per cent. over pre-war figures. At present I believe the increase is 133 per cent.

The BRITISH MEDICAL JOURNAL has fought for and obtained in a great number of cases increases to whole-time medical officers of 50 per cent. and over. It is not suggested (and quite rightly so) that their salaries should be reduced at present, yet they are in a much more comfortable position than panel practitioners, as they have fixed hours and no night work, while a panel practitioner cannot call his soul (or body) his own, as he is always expected to be on duty. The chemists who take service under the Insurance Act take good care that they are not always at the beck and call of insured persons.

When the question of a State Medical Service was being talked about some time ago, one of the advantages I saw in it was that the medical men would have a very good case for demanding an eight hours day. We might then be able to carry on in the calm "go-as-you-please" fashion of a Government office instead of struggling to keep up with our work (including the keeping of records) and wearing the flesh off our bones in the endeavour to decide whether we should notify a case of scarlet or enteric fever and receive for our trouble the magnificent fee of one shilling. By the way, are we still at war with Turkey? If so why so, and if not why not the notification fee raised to half a crown? Let M.P.'s grant themselves free first class railway tickets and propose to raise their own salaries.

There is a very widespread impression in the profession that the Insurance Acts Committee of the British Medical Association do not stand up to the Government as they might, and unless this impression is removed it will act prejudicially on the Association. When I use the word "profession" I mean those of us who are in general practice, and more particularly those of us who are panel practitioners.

While saying this I would at the same time earnestly appeal to all medical men to join the British Medical Association, which is far and away the largest body of medical men. Do not be selfish, do not say "What benefit shall I reap by joining the Association?" If you receive no personal benefit remember that you are helping many of your brother chips. If you are dissatisfied with the present conduct of affairs it is all the more necessary that you should join and make your point of view felt in the meetings, both local and general, of the Association. Many men who take no active part in the work are those who are most ready to criticize, and yet they receive the same advantages as those who have fought for it, and who have borne the burden and heat of the day.

—I am, etc.,

PHILIP LAMBERT BENSON.

Steeple Claydon Bucks May 12th

INSURANCE.

MEETING OF BUCKINGHAMSHIRE INSURANCE PRACTITIONERS.

A GENERAL meeting of the insurance practitioners on the Buckinghamshire panel was held at the Royal Buckinghamshire Hospital on April 29th, when Dr. BELL was in the chair.

Dr. BELL briefly introduced Dr. BOYTON, the regional medical officer, who then gave detailed advice as to the filling up of the new record cards, the procedure adopted when a second opinion was required the filling up of certificates and other matters. He stated that he wished to help the doctors, and to make their path as smooth as possible. At the conclusion of this useful address questions were invited and many points were dealt with that were not very clear in the instructions. The greatest trouble experienced by the doctors was said to be in regard to their keeping correct lists of insured persons. It was quite impossible to do so under the present system, and much time was lost in searching for record cards that were not sent, slips were sent and not altered on women's cards, getting a record card in envelopes supplied the case of the men over 70 years of age who are liable to be overlooked, enlisted men who have returned and not taken the trouble to get a new card, etc.

Finally the following resolution was directed to be sent to the Ministry of Health:

"That this general meeting of the practitioners on the Buckinghamshire Hospital Committee wish to express its great dissatisfaction at the state of affairs which exist in the keeping of the lists of insured persons by the Insurance Committee of this county. The record cards issued to practitioners are very incomplete, causing much extra work and great exasperation among practitioners."

A hearty vote of thanks was accorded to Dr. Bontor, and the meeting concluded after partaking of tea kindly prepared by the matron of the hospital.

A meeting of the Local Medical and Panel Committee was held on the same day at the Royal Buckinghamshire Hospital, with Dr. BELL in the chair. Dr. DICKSON reported that friendly societies were making arrangements for the nursing of their members. It was reported that a doctor had been fined £10 for a breach of the certification rules. The revised terms with chemists were agreed to. Consideration was given to the letter from the Ministry of Health (SUPPLEMENT, April 16th, 1921) dealing with anaesthetists' fees, wherein a new form of claim was suggested (G.P. 19), and in which the practitioner performing the operation declares it to be within his terms of service. It was thought to be very unwise to adopt this, and to be far better to adhere to the decision that the Panel Committee should decide this matter.

Mileage Scheme.—Correspondence was produced from adjoining areas as to the method of making mileage claims. In some districts the medical cards were marked with the distance and the lists compiled at the office. It was carried: "That in future years some method of making lists of mileage claims at the insurance office should be urged."

Surgery Notices.—It was decided to have five hundred notice forms for practitioners to put up in their surgeries giving notice that medical cards must be produced when coming for treatment or a fee would be charged.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE. ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Lieutenants promoted:
J. Lorimer, L. C. D. Irvine, N. L.
D.S.O., A. G. L. Reade, O.B.E.,
W. G. Evans, J. H. Lamb, E. F. Murray.

ARMY MEDICAL SERVICE.

Colonels H. N. Dunn, C.M.G., D.S.O. (late R.A.M.C.), and H. J. M. Buist, C.B., C.M.G., D.S.O., retire on retired pay.

ROYAL ARMY MEDICAL CORPS.

Major S. McK. Saunders is restored to the establishment.
Captains G. K. Maurice, D.S.O., M.C., and D. W. Pailthorpe are seconded for service with the Egyptian Army.
Captain A. W. Benvis retires, receiving a gratuity.
Temporary Captains relinquish their commissions and retain the rank of Captain: T. M. Richardson, V. H. L. MacSwiney.

ROYAL AIR FORCE.

MEDICAL BRANCH.

T. P. Harpur is granted a temporary commission as Flying Officer with effect from and seniority April 19th.

BIRTH.

SAYERS.—On May 16th, at Bushy Lodge, Teddington, to Dorothy and Patrick Sayers, M.R.C.S., L.R.C.P., a son.

to be a satisfactory electorate, and that the method unduly restricts the choice of the meeting. It will be noted that the election by postal vote of 24 members by grouped Branches is untouched, as is also the election of members of Council by Oversea Branches. Other proposed changes in the Council are to make the outgoing Chairman of Representative Meetings *ex officio* a member of Council for one year after he leaves the chair and to make the Deputy Chairman of Representative Meetings *ex officio* a member of Council.

The last large section of the report deals with the Committees of the Association. It proposes to make more precise the references to most of the Committees, to decrease the size of the Finance Committee while increasing that of the Journal and Science Committees, and so to alter the method of election of the Science Committee that 4 of its 10 members will in future be elected by the Representative Body instead of all being elected by the Council. Besides this, power is given to Committees to consult each other directly instead of, as at present, indirectly through the Council, and to any Standing Committee to co-opt persons who may be thought specially qualified to assist the Committee in its work.

None of these changes are to come into operation at once. The intention is that the Representative Body shall freely express its opinion this year on the changes proposed; such of them as are accepted will be placed formally as new Articles and By-laws before next year's Annual Representative Meeting. There can, therefore, be no fear of hasty and ill-digested changes in the constitution.

Those who study the report will be struck with the fact that a careful and long-continued scrutiny of the existing constitution and machinery of the British Medical Association by a body of experts who were by no means prejudiced in favour of leaving things alone has resulted in a report which recommends no revolutionary changes and which expresses the deliberate opinion, endorsed by the Council, that on the whole the present constitution has proved well suited for carrying out the objects of the Association. It remains to be seen whether the Divisions and Representative Body are also of this opinion, and how far they think the changes now suggested will tend to make the Association still more useful to its members and to the profession.

THE MINISTRY OF HEALTH.

THE vote to complete the estimate for the Ministry of Health had a quiet passage through the House of Commons last week. Sir Alfred Mond, on beginning his speech, appealed for consideration because of the newness of the Ministry and the difficulty of its task, and in concluding it spoke of a time when disease would be a thing of the past and illness a kind of forgotten tradition. While agreeing that the Ministry has a great future in helping the nation towards higher standards of health and physical development, we think it will be prudent at this stage not to promise too much. Dr. Farquharson again directed attention to the disappointing results of sanatorium treatment when compared with the glowing promises of twenty years ago, and expressed the opinion that it would be impossible to have a tubercle-free population in this country. Without attempting to adjudicate on a matter so complex and uncertain, it may be said, without fear of contradiction, that the facts about tuberculosis illustrate the point we desire to make. It would, we think, be both wise and politic, even

in a peroration, to impress on the public mind the truths that the increase of industrialism and of the proportion of the population in urban accumulations are constantly making the preservation of health and the prevention of disease more difficult, and that, if things are not to grow worse, the hearty and intelligent co-operation of the individual as well as the expenditure of public money are necessary.

A good deal of the short time the House gave to the debate was spent in getting at the truth about a fairly simple matter of fact—namely, the number of medical officers Dr. Addison had appointed to the Ministry. By counting in the regional medical referees or consultants appointed under the Insurance Acts, which was perhaps fair, and by reckoning the medical inspectors of the Local Government Board who became medical officers of the Ministry of Health as new appointments, which certainly was not, the *Times* got a total of 50 new appointments and of about 100 medical officers altogether. The official calculation by omitting the regional referees gave a net increase of 13 and a total of 59 medical officers. Technical justification for the omission of the referees is found in the fact that their appointment was approved by Parliament in 1914 but suspended during the war; but in any case to get a true comparison they should be excluded, for the work of the medical department of the Local Government Board had nothing to do with the Insurance scheme. Of the new medical officers six, Dr. Addison states, were appointed to reinforce the staff dealing with the prevention of the spread of epidemics and kindred matters, especially with a view to the requirements of the sanitary cordon urgently necessary in the post-war period; from what Sir Alfred Mond said it would appear that the reference is to the port sanitation work in which the central authority can give essential help, as was long given by the Local Government Board. It may be true that in this and other directions the Ministry is not yet doing much more medical work than its predecessor, but it seems obvious that a Health Ministry must have an adequate medical staff if it is to be as useful as the country has been led to expect it will be. The charge of extravagance in this matter of the appointment of medical officers has broken down completely.

Sir Alfred Mond, like his predecessor, feels the oppression of the housing problem, but could say that though there was a shortage of certain classes of workmen good progress had been made; cost had decreased a little and local loans had been raised without difficulty. In spite of all this, each house erected by local authorities is to cost the State £50 more a year than its rent, so that the best news the Minister had for the tax-payer was that the estimate originally made in many districts of the number of new houses needed had proved to be enormously beyond the actual demand. Anyone who a year ago had hinted at an over-estimate would have been called reactionary, and the reduced estimate is not now accepted by the National Housing and Town Planning Council; Sir Alfred Mond spoke of an ultimate gross number of 300,000 new houses of different classes, but the Council would appear to adhere to the estimate of a million houses for England and Wales alone. This estimate was founded on the results of the housing survey made under conditions laid down by the Ministry of Health, but did not, perhaps, take sufficient account of the possibility of repairing old houses—often much better built than modern—and rendering them habitable and healthy.

Not very much was said about National Insurance. The new Minister stated that he had begun by doubting whether the regional referees were necessary.

but had been convinced of their utility. Sir Watson Cheyne expressed the opinion that the panel could be improved if it were made easier for the insured person to change his doctor so as to encourage competition, and the Minister agreed. Another proof is thus afforded of the wisdom of the policy of the British Medical Association in insisting on free choice of doctor. Sir Watson Cheyne's remarks also throw from Sir Alfred Mond the statements that the establishment of a State medical service was not in contemplation, and that he did not think anyone wished to destroy the voluntary character of our hospitals. In this opinion we fear he is mistaken; but it may be deduced that he is himself anxious that the voluntary system should be maintained.

The general impression produced by his share in the short debate (of which a full account appears in our Parliamentary Notes this week) is that Sir Alfred Mond is disposed rather to allow things medical, so far as he is concerned with them, to follow the natural line of development than to endeavour to bend them to conform to any theoretical preconceptions.

THE PROBLEMS OF INDUSTRY.

THE newspapers are filled with the tale of labour troubles and struggles, but these accounts reveal only a one-sided appreciation of the magnitude of the problems involved and the efforts that are being put forth to secure both better and more efficient working in industry. To the student of these problems two books recently issued may be commended. One by Archibald Chisholm,¹ entitled *Labour's Magna Charta*, is a critical study of the labour clauses of the peace treaty and the draft covenant and of the recommendations of the Washington International Labour Conference; it is exceptionally well written and sets out the economic problems of international labour in a lucid and interesting manner. Considering only those parts of the work which have a distinctly medical bearing, we note how far-reaching is the influence of physique, hours of work, food, and fatigue. Physique as a factor in industrial efficiency is of prime importance. Chatterji is quoted as declaring that Indian labour is really dear, though wages are low. He stated that if an English mill engaged on a similar work were compared with an Indian mill it would be found that, while a much greater number of employees were engaged in India, the output would not be worth more than 65 or 66 per cent. of the value of the English output. This low efficiency applies to child labour and to a lesser extent to female labour. As a means of meeting the needs of women who must work, reference is made to a "half-time" system which has been in operation for some years in the United States, and has been applied also to apprentices. While the great majority of workers are engaged all day, some work from 8 a.m. until noon. One great firm declares that it has found the system so successful that it is prepared to adopt it on a large scale. Industrial fatigue is, of course, another factor in efficiency. It is defined as "a condition of lower capacity for work, which follows or occurs during the performance of work, of which it is the direct result." It may exist, therefore, without weariness. Under the Taylor system, whereby causes of fatigue are largely reduced, the workman's output has been found to increase by as much as 60 to 100 per cent., and in addition a considerable saving of material has been effected. The influence of fatigue upon efficiency is readily appreciated by the doctor who typewrites his own letters and compares the number of mistakes made in the evening after a hard day's work with his morning performance. Adequate food is another important

factor: the better-fed worker is usually the more efficient. It is said that figures show that before the war Germany consumed 20 per cent. more food in proportion to the number of industrial workers than the United Kingdom, and France 15 per cent. more. Mr. Chisholm quotes an interesting speculation of Dr. Ellsworth Huntington which suggests that health is a greater determinant of trade cycles than the condition of crops. For every death, he holds, we have about ten cases of severe illness, and owing to the disorganization of industry caused by deaths and sickness, bad trade ensues. He endeavours to show that a high death rate regularly precedes hard times, and that a low death rate is followed by a period of prosperity. The relative inefficiency of Indian labour may be connected with a high death rate, for the average duration of life in that country is given as only 23.5 years. The second work is a massive volume by Dr. René Sand² on industrial organization, social medicine and civic education in England and the United States. The book is the result of three personal investigations made in these countries in the years 1918-19, the first at the instance of the Belgian Government. His journeys were extensive, his investigations most thorough, and the results are of great value. The primary object of his visit to the States was to make a study of "Taylorism," which has a wide vogue in that country and to a lesser extent in Europe. At present it seems to be the last word in industrial progress, and may be epitomized as the application of the science of organization to production. The physiology, psychology and social condition of the worker are studied, for in their improvement is found the key to efficiency. The health of the worker must be assured, or else he cannot do good work. General and professional education must be high, so that talent may be developed. Contentment must be secured, for that determines the wish to work. The author has collated the efforts that are being made to attain these ends by great industrial organizations, and he shows how extensive and far-reaching are the effects already secured. A compilation of this kind is of great value to those engaged in industrial and State medicine, and presents points of interest to every physician. On page 478 is a most interesting table in which the infantile death rate is correlated with the annual income of the father. With wages less than 150 dollars the death rate is 170 per 1,000, at 500 dollars it has fallen to 130, at 700 dollars to 108, at 1,000 dollars to 80. A like correspondence is found between wages and the health of the workers. One of the conclusions to be drawn from the evidence of these two books is that low wages mean poor work and a more costly production than high wages. The economic failure is further aggravated by the drain on the public purse due to the piling up of costly remedial expenditure that could be better utilized in more remunerative forms of medical and sanitary provision.

ROYAL SOCIETY CONVERSAZIONE

THE annual conversazione of the Royal Society was held at Burlington House on May 11th, and was so well attended that it was practically impossible to see a tenth part of the exhibits and demonstrations. Fortunately arrangements are always made for an earlier press view of the latter. This year amongst the thirty-nine demonstrations figuring in the catalogue there was none having any direct bearing on medical science, though the exhibition contained much of great general interest. Mr. L. T. Hogben, of the Imperial College of Science, demonstrated the effects on tadpoles by feeding them with pineal gland. Hitherto there has been no proof of any physiological function exercised by the pineal body, but Mr. Hogben has succeeded in showing, in tadpoles at least, that it has some controlling power over the pigment cells. *Macroscopic*

¹ *Labour's Magna Charta*. By Archibald Chisholm, M.A. London: Longmans, Green, and Co. 1921. (Pp. 192. 8s. 6d. net.)

² *Organization Industrielle, Médecine Sociale, et Éducation Citoyenne en Angleterre et aux États-Unis*. By Dr. René Sand, of Dr. Willers. Paris: J. B. Baillière et Fils; Bruxelles: Librairie Larmurion. 1920. (Roi. 8vo. pp. 295; 30 francs.)

and microscopic preparations showed that in the pinched tadpoles there is a very evident contraction of the melanophores, an effect that is not produced by feeding experiments with any other endocrine organ. Mr. C. Tate Regan, F.R.S., gave a demonstration of part of the life-history of the common eel, founded on the researches of Dr. J. Schmidt, who showed that the freshwater eel of Europe breeds in the Atlantic, south-east of Bermuda. A series of larvae, from the middle and western North Atlantic, with long and slender pointed teeth, were exhibited, together with a photograph of the metamorphosis into the elver. The accompanying models illustrated the changes from the yellow eel with its thick lips, small eye, and compact pectoral fin, into the thin-lipped, large-eyed silver eel with pointed pectoral fin, the latter form of eel being that which migrates to the ocean to become mature. Dr. John Rennie demonstrated the mite, now named *Tarsonemus woodi*, which has been claimed by Bruce White to be the causal agent of Isle of Wight disease in bees. White showed that the mites perforate the tracheae, and by their numbers obstruct the spiracles and thus deprive the bees of the power of flight. Mr. J. E. Barnard gave a demonstration of the microscopic appearances of sections by ultra-violet light. Certain structures, owing to their differences in chemical composition, give different fluorescent tints, and the images obtained are often dissimilar to those obtained by ordinary staining methods. The light filter used was a glass made by Chance, which is transparent to the ultra-violet radiations, and the quartz substage condenser was of the "dark-ground" type. A most interesting and instructive astronomical model designed for educational purposes was exhibited by Dr. William Wilson. This model, which has received great praise from leading astronomers and teachers, not only demonstrates the more familiar motions of the sun, earth, and moon, and the various phenomena resulting therefrom, but is capable of simple analyses of each particular motion. The apparatus is most ingenious.

NORTH EUROPEAN CONFERENCE ON VENEREAL DISEASES.

THE first North European conference on venereal diseases opens to-day at Copenhagen, under the auspices of the League of Red Cross Societies. Besides the Danish Red Cross Society, which is acting as host and convener, the conference will be attended by representatives of the following national Red Cross Societies: Great Britain, Holland, Norway, Sweden, Finland and Germany. The Governments of these countries will also send delegates. The results of the all America conference on venereal diseases, held at Washington in December, 1920, will be presented to the Copenhagen meeting by Lieut.-Colonel Ritchie, Assistant Chief of the Division for Combating Venereal Diseases, League of Red Cross Societies. The conference will be opened by the chairman of the Danish Red Cross, Professor Høffding, after which Sir David Henderson, Director-General of the League of Red Cross Societies, will deliver an address. A general summary will be given of the conditions in each country, and the medical and educational measures against venereal diseases will be discussed. The following special problems are to be presented: (1) The supply and cost of arsenical compounds for the treatment of syphilis; the possibility of establishing an international standard for the export and import of such compounds: discussion to be opened by Dr. Kristian Grøn, of the Norwegian Red Cross Society. (2) The provision in important ports, by international agreement, of facilities for the treatment of venereal diseases among sailors, and measures to be taken in connexion therewith: discussion to be opened by Colonel L. W. Harrison. (3) The part of the Red Cross in combating venereal disease, its relation to government and voluntary agencies: discussion to be opened by Professor C. E. A. Winslow, of the League of Red Cross

Societies. (4) Medical measures for the prevention of venereal diseases: discussion to be opened by Dr. Meisild, of the Danish Red Cross Society. Following this meeting at Copenhagen, the League of Red Cross Societies expects to arrange other conferences of groups of nations, both in Europe and in other parts of the world.

THE HARROGATE WATERS.

PROFESSOR ARTHUR SMITHIELLS, C.M.G., F.R.S., has completed the survey of the Harrogate waters entrusted to him four years ago. He has been assisted by Mr. W. Lowson, B.Sc., F.I.C., lecturer in analytical chemistry in the University of Leeds, where Professor Smithiells occupies the chair in that subject, and also by Professor Bragg, F.R.S., who was responsible for determinations of the radio-activity of the waters; by Professor P. F. Kendall, who reported on geological questions; by Professor Goodman, who advised on engineering problems; by Mr. G. R. Thompson, B.Sc., formerly Professor of Mining, and by Professor J. W. Cobb, B.Sc., F.I.C. Details of the results obtained have not yet been published, but we are informed that the analyses when compared with previous records show that the special characteristics of the Harrogate waters are fully maintained. Improvements have recently been carried out which have led to an increase in the sulphur content in the sulphur bathing waters; the storage loss can now be kept at the remarkably low level of 5 per cent. The Harlow Car alkaline sulphur water used in skin diseases, hitherto only available at its source two miles from Harrogate, has now been brought to the Royal Baths, the difficulty of transmission without deterioration having been overcome. Mr. Arnold Woodmansey, M.Sc., has been appointed full-time analytical chemist to the Harrogate corporation to supervise the collection, storage and distribution of the mineral waters. He has demonstrated the presence of manganese in all the chalybeate and most of the sulphur waters, and it has been shown that the barium content of several of the wells has been increased, in one instance by as much as 50 per cent. The British Spa Federation has instituted a system of training for bath attendants; persons attending the balneological training school at Harrogate are required to have had a minimum of eighteen months' practical work at one of the spas of the Federation, and to have attended a series of lectures given by members of the local medical profession; they are then submitted to a primary examination. After further practical work on specialized and more difficult treatments, and a further series of lectures, a candidate is eligible for the final examination. Nearly all the members of the Harrogate Baths staff have attended lectures during the past winter and have passed the primary examination. It is expected that next winter a considerable number of candidates from other home spas will attend the course.

THE UNMARRIED MOTHER.

THE aims and needs of the National Council for the Unmarried Mother and her Child were put forward at an "At home" given by Dr. Mary Scharlieb at her residence on May 12th. The object of the National Council is to correlate the work now being done on this subject all over the country, and to influence public opinion in favour of the bill which has been prepared by the Council. Captain G. E. W. Bowyer, M.P., is in charge of this measure, and is keenly endeavouring to obtain a second reading for it in the House of Commons. The main features of the bill—which was introduced last year by Mr. Neville Chamberlain on the Council's behalf—are that proper responsibility for the illegitimate child should be placed upon the father, and that subsequent marriage should legitimize children from the date of marriage. Besides the work involved in trying to amend the existing law, the Council is carrying on a great deal of educational work throughout the country. While at first it did not consider that dealing with actual cases came within its programme, a deaf ear could

not be turned to the individual cases of hardship which have come to its notice, and the care of unmarried mothers and their children is now included within the scope of its activities. Maternity homes are found for expectant mothers, hostels for mothers and children, and work is found for mothers, with the object, if possible, of keeping mother and child together; for no longer in these more enlightened days is it thought desirable to separate mother and child in different institutions, as used to be done. When it is realized that 80 fresh cases were dealt with last month by the Council, and that the number of illegitimate births in England and Wales last year was over 42,000, the necessity for the work of the National Council is obvious. Unfortunately, with the increase in unemployment, the difficulties in placing mothers in suitable employment have increased. At Mrs. Scharlieb's meeting the excellent work that the National Council is doing was made clear, and its financial needs were ably pleaded. Its efforts to bring the law of England on illegitimacy into line with that of other civilized countries, and the educational and charitable work it is doing, are worthy of increased support.

THE TREATMENT OF ALCOHOLISM.

In his last annual report to the Homes for Inebriates Association, Dr. F. S. D. Hogg gives an account of the year's work at Dalrymple House, Rickmansworth, of which he is the medical superintendent. Certain of his general conclusions, based on a long experience of the institutional treatment of alcoholism and drug addiction, seem worthy of note. Thus he considers that admission under the Inebriates Act is the best course both for the patients and their friends in a large number of cases. No kind of distinction is made at Dalrymple House between either class, but while private patients can end their stay at any time, and sometimes do leave prematurely without giving themselves a chance of success, those under the Act must remain in residence until the period for which they have signed expires, unless they are previously discharged, or go away on leave of absence under the Act. The last-named procedure he finds a useful method of practically discharging a patient while still keeping in touch with him and being in a position to help him and his friends should a relapse occur. In regard to treatment, Dr. Hogg says: "I continue to adopt no single form of drug therapy in all cases, for I know no treatment that is universally applicable. Each case has to be studied, and such treatment as is considered appropriate is adopted. Alcohol is given at first to those who require it, but after the first two or three days it is rarely demanded; for drug habitué's gradual reduction is usually employed. My object is to wean a man from alcohol, or from the particular drug for which he has an addiction, with as little discomfort to him as possible." This, we believe, represents the opinion of those, in this country at least, who are in the best position to judge. Most authorities will probably also agree with the view here expressed that, when the poison has been withdrawn from the patient's system, the next step is to cure him when possible of any diseased condition that may be at the root of his drink or drug impulse, and restore him to a sound physical condition. Thereafter the object is to train the patient's mind to resist the morbid impulse by cultivating his self-control, strengthening his will power, and making him realize that part of his cure lies in his own hands. Above all, the inebriate and the drug slave must be made to understand that abstinence is an absolute necessity. The first principle in the treatment, not only of dipsomania and pseudo-dipsomania, but of chronic alcoholism as well, is total abstinence. As has been well said by a writer on this subject, it is idle for the drunkard to hope that he can ever drink habitually in moderation. With regard to liberty to leave the grounds of the institution, Dr. Hogg reports that a considerable amount of freedom can be given to some patients within a few days of admission, and after

two to four weeks' residence the large majority can be given parole. His patients are all males and mainly, if not wholly, drawn from the upper and middle classes, and this experience, therefore, may not quite coincide with that of the medical superintendents of all inebriates' retreats.

THE HISTORY OF MEDICINE.

The second Congress of the History of Medicine will be held in Paris during the first five days of July under the presidency of Professors Jeanselme and Menetrier. The congress will be opened at the Faculté de Médecine at 9 a.m. on Friday, July 1st, by the Minister of Public Instruction, and discussions will take place on the afternoon of that day and the four following days. The subjects chosen are the history of hospitals and of public provision for the sick in all countries; the diet scales of man and the diet of animals in antiquity and in the middle ages; the history and nature of the great historical epidemics; the part played by pharmacists in the development of biology, and the history of opizootics. Visits will be paid to hospitals, museums, and central hospital pharmacies. After the closing session on Tuesday there will be a reception at the Hôtel de Ville. During the congress an exhibition will be open containing manuscripts, books, engravings, paintings, medals, and instruments of historical interest. The subscription—40 francs for members and 20 francs for members' relatives—should be sent to M. Fosseyeux, 3, Avenue Victoria, Paris.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Ministry of Health.

SIR ALFRED MOND'S DECLARATION OF POLICY.

IN Committee, on the vote for £15,245,098, Sir Alfred Mond made, on May 12th, the annual statement on behalf of the Ministry of Health. Recalling that the Ministry was established as recently as the year 1919, and that it had taken over the already heavy burdens of the Local Government Board, National Insurance, and the development of health, and had had placed upon it the responsibilities of housing, he pointed out that comparisons between the expenditure of the Local Government Board and that of the new department could not fairly be made. In spite of their difficulties, the Ministry had reduced the estimate by £3,300,000 as against what it was last year, including what had been saved in the stoppage of war services. There was an increase on administration of £594,000, an increase in housing grants of £251,000, an increase on miscellaneous health services of £970,000, a decrease in insurance grants of a considerable sum, and a decrease on special services arising out of the war of £7,000,000. It should be borne in mind that a great part in the increases and decreases in the grants resulted automatically from legislation passed by the House, and especially from the operation of the National Insurance Act. For instance, about £2,000,000 representing grants in aid, payable under the Act, were not subject to change by the Ministry. He pointed also that a considerable sum in respect of the establishment represented an expenditure on services delayed by the war, and of a temporary character. In regard to housing, Sir Alfred Mond said that his position reminded him of that occupied by some remote ancestors of his in the land of the Pharaohs some few thousand years ago, who were asked to make bricks without straw—the trouble in the present case was to find the money. The situation on May 1st was that they had 176,000 houses under approved tenders, 160,000 under signed contract, and 102,000 houses in course of construction. The amount of skilled and unskilled labour had risen from 129,000 on October 1st to 130,000 on May 1st; they were completing nearly 6,000 in April, and would complete nearly 7,000 a month hence. Partly, as he believed, on account of the depression local authorities were greatly reducing their estimates of requirements, and the Minister hazarded the view that this might be because many people seeking houses a year or two ago might be contemplating emigration. But, on the best estimate of reviewed arrangements, the loss to the State on each house erected by local authorities under the present scheme would be about £60 a year, and that put

into the terms of 200,000 or 300,000 houses meant a net loss to the State and burden on the taxpayer of between 12 and 18 million sterling a year. In addition, a grant of 15 million had been voted for the private builders' subsidy, and there were other heavy obligations. He was glad to say that the price of houses was coming down. Tenders for the average sized house had come down from £950 in August to £855, and they were still dropping. Roughly speaking, he regarded 300,000 as the limit for the number of houses to be built in England and Wales under these conditions, and if they could get along with less he should cut down the figures. In closing the review of this part of his work the Minister described housing as a kind of cuckoo's egg laid in the nest of the Ministry of Health which had pushed little chicks of health out of the nest.

Coming to what he described as being really the work of his department—that was considerations of health—Sir Alfred Mond dealt first with a criticism in the press on the medical establishment of the Ministry. He said that, whereas the old Local Government Board had a relatively small medical staff, and comparatively few medical duties, the National Health Insurance had a much larger staff, and when the two were joined together that automatically increased the staff of the Ministry of Health. On April 1st, 1919, the number of pensionable medical men in the Local Government Board and the Insurance Commission of England and Wales was 46, the number in the Ministry of Health at present was 59—that was a difference of 13 distributed as follows: Maternity and child welfare 2, tuberculosis 2, venereal disease 2, port isolation hospitals 3, statutory medical service and intelligence work 3, and work for the Home Office 1. These were additional functions to the work which was being looked after by the medical staff of the Ministry of Health, apart from the newly established regional officers. He thought it was not quite realized how big was the sanitary work the department supervised. No fewer than 1,800 sanitary authorities, 114 port authorities, 646 Poor Law Unions looked to it for guidance, and 1,029 isolation hospitals and 4,220 public vaccination districts had to be inspected. There was a vast number of maternity centres and tuberculosis sanatoriums also requiring attention. He had stated why the increase in the medical staff of the Ministry had taken place; they were not up to their full establishment on the medical services, and he did not propose to fill the two vacancies at the present time. There were also some six temporary appointments the work of which had lapsed, and he intended to discontinue them. He understood there would be the possibility of the reduction of two more of the permanent established staff, so there would be a reduction altogether on establishment and non establishment of between nine and ten. That was as far as they could wisely go at the moment in the direction of economy in this very important service, upon which so much depended and so much more would depend in the future. He was glad to say that the health rate of the country was good and the birth rate was rising and the death rate declining. Particularly marked was the continued steady decline of infant mortality. No one who had seen the maternity and infant welfare work could doubt the services rendered. He remembered what was perhaps the first centre or home of this kind in the world, which was started in his own constituency by his wife many years ago. Any one who had seen how much good a relatively small institution, wisely guided, could do would certainly wish to see the work extended all over the country. He was glad to say that the number of health visitors had gone up from 1,400 to 1,700, the number of non resident centres had risen from 1,400 to 1,900, the number of maternity homes had gone up from 740 to 1,200, and the infant hospitals for children under 5 years had risen from 50 to 367. Whatever economies they might be forced to make, he hoped that they would not economize on the infant life of the country, that would be the poorest and most miserable economy.

They were making good progress in dealing with tuberculosis. The work that had been done was beginning to bear fruit—the first fruit of the work done by the Ministry of Health and by the enthusiasm and zeal of his predecessor in office, who had so much special knowledge of the subject. They might achieve relatively little at the time, but they could be confident that, if they proceeded on reasonable lines of care and treatment, if they proceeded on the lines of teaching people about hygiene and how to avoid the disease rather than dealing with it only when contracted, they could produce a great improvement in the standard, physical and therefore moral, of this country. It was the best investment the country could make, for after all the greatest curse and unhappiness was ill health.

He was glad to say that venereal disease work was

making good progress. While he did not believe in covering the country with posters to draw attention to the evil and over emphasize it, he was quite convinced that they must steadily proceed with propaganda and with treatment. He was considering now the issue of a new circular to explain the policy of the department, which consisted of a sane and moderate view of this very complex and difficult problem, which had a moral and social as well as a medical side. The moral and social side should never be overlooked; it was more important in some respects than the medical. While quite prepared to assist to have the health of the nation protected against this very terrible disease, he was not prepared to accede to the demand of those who seemed to him to regard the question—with perfect sincerity and great enthusiasm—merely from the aspect of the medical cure without taking the wider view.

Sir Alfred Mond next referred to the establishment of medical referees in connexion with National Health Insurance work. The appointment of some thirty three whose duties were largely connected with the examination of members of approved societies, had been criticized in the press; but these appointments were really made as long ago as 1914 by the House. It was no new fantastic idea which had been elaborated, but the redemption of an old pledge. The object in the main was that approved societies should have an independent and carefully chosen man in each area, to whom they could submit cases in regard to which they were doubtful whether such cases ought to remain on the books, or were to resume ordinary occupations. It was very difficult sometimes to determine whether a man was malingering, there was a danger—he would not say a bias—on the part of the man's medical attendant to give him the benefit of the doubt, but it was in the interest of everyone that a man should return to his normal life as quickly as possible. When he entered upon his office he had some doubts as to the ability of these medical referees, and he asked six of them from different parts of the country to come and have a talk with him. He was very much impressed with the value of their work and of the way in which their work was being appreciated, both by the approved societies and by the most intelligent of the ordinary general practitioners in the district in which they worked. They acted also to a considerable extent as consultants, and were ready to act in such capacity to the panel doctors when the latter had more than ordinary difficulty. He believed that their presence was welcomed by the medical profession as a whole. They were engaged only as an experiment for a certain number of years, but were performing good and useful work, and it would be a very great mistake, under the pressure of clamour or prejudice, to do away with a very fruitful source of development of this work by men very carefully chosen and very able, before there was time to judge how far the work would be of utility.

He believed there was a great future before the Ministry of Health. He regretted very much that one of its important sections, namely, research, had been detached, he hoped it was going to be joined on again, for that was one of the most fruitful sources of developments. There were many other matters on which he would have liked to speak, but he would say broadly that he would try to extend those activities which would bear most fruit at the least expense and show the greatest amount of good. He should deplore beginning his economies at the wrong end. Such a course would be like that of people who, when they did not feel well, took some patent medicine and so got thoroughly bad, and then had to spend months under the doctor and pay a bigger bill than if they had started with him. There were so many false economies. A friend broke his leg in running after a motor bus, when it would have been much cheaper to have taken a taxi. They must not carry such policy into their national life, but must have a wide vision for the future. He felt his responsibility very greatly. He recognized there was a great work to be done, and if they could assist to put a few small stones in the great building of national health and national wealth he should indeed be glad.

Debate.

In the course of discussion Mr. C. Edwards brought up the complaint made by members of the Standing Joint Committee of the Industrial Women's Organization who were appointed on one Consultative Council. They said that in the first instance their reports were mainly ignored, and that afterwards the Council was not called together. Orders were issued by the Ministry without any reference to such Councils for an opinion. Women members of the councils were so dissatisfied with what was being done that they sent in their resignation.

752 MAY 21, 1911]

Colonel T. B. Mildmay, after a tribute to Dr. Addison for his sympathy with voluntary hospitals, expressed his confidence in the Committee presided over by Lord Cave, whose final report was shortly expected. He asked the Government hospitals were appreciate that many of the principal London hospitals were already in financial crises. The London Hospital management was being compelled to close two hundred beds at once, though 761 poor people were waiting for admission. Lord Knutsford had told him that the hospital was getting further into debt at the rate of £2,000 per week; King's College Hospital was, he understood, being forced to close 150 beds; St. Thomas's was being forced to close a hundred, and so on. At the Middlesex Hospital, with which he was associated, they had been obliged to get an overdraft for £15,000, against which legacies were pledged, and, even supposing that legacies were maintained in the coming year at the rate of £3,500 a quarter, and by the end of the year would have exhausted their credit. He agreed that Sir Alfred Mond could not anticipate the report of Lord Cave's committee, but did suggest that he might make one helpful move. These difficulties of Middlesex Hospital were due mainly to the treatment of naval and military patients during the war, and the cost to the hospital was £32,000 more than the Government occupied three fourths of the beds during that period, and the cost to the hospital was £32,000 more than the Government paid. Surely that might be claimed as an ordinary debt. The figures had been checked by the hospital accountant and auditors of the King's Fund. If this sum were repaid the hospital would be freed of debt, and they would have breathing space. If it could not be liquidated without delay, let the debt be acknowledged, and they would be able to borrow money against its acknowledgement. Lord Hambleden had expressed himself in the same condition. They were not asking for a subsidy, but for payment for services rendered. He was the immediate difficulties which were daunting them. The system of payment of patients had been introduced really looked upon the financial future of hospitals as fairly hopeful. The system of payment by patients and recognized by many, particularly the Middlesex, and was promising really well; it had been accepted by the patients and recognized by them as just. Again, the generous decision of the National Deposit Friendly Society to devote one-third of their surplus—over £125,000—towards the payment of the cost of hospital and nursing services to members was a splendid sign to be imitated, he was confident, by all other approved societies.

Earl Winterton said he was interested in the negotiations between the London hospitals and the Council of Approved Societies in London. There was a possibility of getting a very much larger sum than Colonel Mildmay had mentioned, from this Council—approximately between £200,000 and £300,000. That would tide over the immediate difficulties. These negotiations were nearly complete.

Sir Watson Cheyne said he desired information on one or two matters. The first was, What (if any) alteration was to be made in the medical services? He presumed that something could be done, because they knew that the panel service could be improved and it would lie between improvement and introducing some new service—a form of State Medical Service. Personally, he should favour finding out what the defects of the panel service were, and trying to improve it, rather than scrapping it and introducing a new service, which certainly would not be at all favourable to the medical profession. Various things were required to bring the panel service into a better condition. Much assistance was required to help medical men to diagnose their cases and also in certain other matters. So far as his own experience in consultation had gone, he had not come across any evidence to support the accusations made against panel doctors, but he thought that in a few cases the statements might be more or less justified. When the Insurance Act was first considered, he welcomed the idea of insurance against sickness, but questioned the doubtful about the question of medical benefit; he welcomed the idea of insurance against sickness, but questioned the advisability of the panel system. One thing wanted was to increase the free choice of doctors. The advantage of a greater choice of doctors would be to reintroduce competition to a very marked degree. He held that a State medical service was undesirable; one reason against it was that it was not worked that was that the State control of industries had not worked satisfactorily. Coming to the question of research, he deplored that the work of the Medical Research Committee had been transferred to the Privy Council. They were told when this was done under the Ministry of Health, and that a certain amount of research was going on in connexion with the old Local Government Board, and that this might be developed. He understood that at present the Medical Research Council was ready and willing to assist in the Ministry of Health. One of the great attractions, and it was men was to have an opportunity for investigation, and it was wished to do research and not to have to go to another body and ask leave. The existence of a proper Research Department was extremely necessary for the future of the Ministry of Health. For if any body required information it was that death were still in the melting pot, and questions must be stantly arise which required research in the Estimates, but apparently were remarks about research. The whole expenditure of the Ministry of Health on laboratory work was £700. There was second heading under which some expenditure came and there were two special inquiries. He was not speaking in criticism

but in the hope of hearing from the Minister that more was to be done in this direction.

Mr. Irving called attention to Circular 185 as in direct antagonism to the speech the Minister of Health had delivered. The circular, he said, was an attempt to save money along pettifogging lines in child welfare. It complained of expense in administration, and in other services in the distribution of milk.

The Minister's Reply.

Sir Alfred Mond, replying to a number of the questions raised, emphatically denied that Circular 185 was inspired by a niggardly spirit. The Ministry had introduced experimentally a new medical service in providing milk for expectant mothers and infants. The experience, after very careful investigation, had been that in certain areas this service had been grossly misused, and that everybody who had wanted milk for nothing had been getting it. Most sympathetic and competent lady doctors had told him that what had happened in various localities amounted to a gross scandal. All that the circular did was to require strict control of the milk, and to place the distribution under medical supervision. Coming to a complaint by Mr. Stewart, Sir Alfred said it rested with the local authority to make by-laws as to tents, vans, and sheds, and apparently they did not yet know what their powers were. The subject, he admitted, was not altogether free from difficulty as regards rating, and apparently as long as there was no epidemic his powers of intervention were small. Dealing with the speech of Sir Watson Cheyne, the Minister said he could set at rest any fears he had of a great extension of State medical service. There was no intention to start a vast system of State medical service. The Ministry was working on the lines of endeavouring to improve the panel system. The panel had been limited and reduced generally to a maximum of 2,000. An insured person not satisfied with his doctor could now leave him by mutual consent or after six months. They were making improved regulations in regard to surgeries. The panel system, he thought, had not worked so badly, and he believed that the medical profession had a great desire to do their best. He believed that the patients, on the whole, were satisfied with the service they obtained. Seeing that it was a great experiment, and the large number of medical men employed, he did not think very serious fault could be found. In his opinion there was a great deal of weight in the argument of Sir Watson Cheyne as to medical research. The question of voluntary hospitals had been giving him very grave anxiety; he expected the Cave report towards the end of the month. He was extremely sorry that certain of the large hospitals deemed it necessary, notwithstanding the fact that the report of the Cave Committee was so closely impending and that the Government would be bound to take action upon it speedily, to close those large numbers of beds, although in a few weeks the crisis might be passed. The Cabinet could not reasonably be asked to bring forward a scheme within the next few days. On the other hand, the approved societies had already set aside £250,000, to be paid during five years, out of their surplus. He should have thought it would have been possible for the hospitals to get their bankers to advance the comparatively small sums necessary for carrying on during the next few weeks. He wondered whether something could not be done in that direction even now.

Dr. F. E. Fremantle, in urging that the Ministry of Health, in its care for economy, should exercise discretion, referred to the case of a local authority which had made ruthless reductions in its estimate, with grave danger, he thought, to the large working-class population to whom it was responsible. On the other hand, he asked for an explanation of the enormous size of the administrative and clerical staffs of the Ministry, which exposed it to the criticism that there was too much red tape, too much letter writing, and too much filing work. He suggested that there should be a checking committee in each office, composed of members of the particular returns also duties it should be to decide the medical staff, he had looked lately necessary. As for the medical staff, he had looked into the extra work which was being done and found that it was extraordinarily large. As for research, the Ministry of Health, in laboratory work, had performed to a great extent what Sir Watson Cheyne had said was not being done. That was the *ad hoc* work in regard to sanitation generally. It was only where the research was of a more general nature that the Privy Council. He assumed that the Director of the last-named department was not far short of a scandal to be looked into not, it would be not far short of a scandal that there were two kinds of research—the *ad hoc* and the research not directed to a special object, but of a general character. It was to get independence of administration that this latter research was placed under the care of the Privy Council. Dr. Fremantle argued from the actual vital statistics of the year that the Ministry of Health was engaged in a winning battle, and expressed the belief that the lessening of mortality was largely due to the improvement of services under the Ministry of Health.

Dr. A. C. Farquharson said he regretted to hear that Sir Alfred Mond proposed further to reduce the medical staff of the Ministry of Health, though this staff was getting collectively a sum rather less than one-third of what was being paid to the mushroom growth in connexion with housing. Instead of an increase in the payment of the medical staff, as had been suggested in the case, there was a diminution of something like £7,336, and the staff was to be reduced in the

near future. He was not concerned as to relative figures of the Local Government Board; he took the problem on its merits. These 80 or 90 medical officers recently appointed were to see that proper services were rendered in connexion with something like 6,000,000 or 7,000,000 insured people. They had to bring themselves into liaison with 12,000 or 13,000 doctors. They had to unite the work of approved societies and professional men. In terms of finance, they had the spending of something like £9,000,000 per annum. Yet a paltry sum of £100,000 was being spent on the whole medical staff of the Ministry of Health, while a sum of £300,000 was being spent on the excrement growth in connexion with the housing scheme. These medical men were very eminent men who had acquired a reputation in their profession before they entered the Ministry, and they would give good service to the State. To propose to cut them down or turn any of them out was the most short-sighted policy of which he could think. As for research, he felt strongly that unless the Ministry of Health had a properly equipped laboratory and properly trained scientists, the functions which was laid upon it by statute in the Ministry of Health Act, must remain dormant. He recalled that it was at his instance that an amendment was made in the Public Health Act which placed the responsibility on the Ministry of Health for the direction and elucidation of research. So far as he could gather from the figures in the estimate, the total sum to be spent by the Ministry on research, including the payment for laboratory attendants, special inquiries into disease and pathological expenses, was £2,444. Compared with the sums that Continental nations had devoted to research, the figure was ludicrous. If this country spent upon disease one hundred times as much as it was spending already, that would not be a penny too much. Yet they had the Ministry of Health, to which they had looked forward with such hope, revealing from the very first its feet of clay. On the other hand, he congratulated the Minister of Health upon the increased expenditure in connexion with maternity and child welfare. Regarding the increase of over half a million sterling in the estimate for the treatment of tuberculosis, Dr. Farquharson said that in his opinion sanatorium treatment had broken down, and he suggested that the Minister of Health should exercise some limit of expenditure on schemes sufficiently tried to be pronounced upon as more or less failures. If there was one person more dangerous than another in respect of these matters it was the platitudinous politician who mixed his politics with sentimental notions regarding sanitary and scientific matters. The most recent scientific work went to show that in this country, at all events, it would be impossible to have a tuberculosis-free population. Dr. Farquharson went on to inquire as to the grant to the National Council for Combating Venereal Diseases. He understood that the amount was about £10,000. He did not doubt that the Society was doing good work, but why should a grant be made to one society and none to the other society which also probably had a good deal of wisdom in its ideas? He raised the question, moreover, whether the Ministry, which had every means of disseminating information, should delegate work of this sort. Finally Dr. Farquharson renewed his appeal to Sir Alfred Mond not to cut down the medical staff.

Mr. Jesson earnestly supported the appointment of the regional medical referees. He read an extract from a letter from a secretary of one of the largest approved societies, complaining of indifference by panel doctors to cases. He did not suggest there were many instances of the kind, but the regional referees would be able to correct them.

Major Birchall regretted any attempt unduly to curtail expenditure upon the Ministry of Health, which he regarded as the "key" ministry of all the other departments.

Dr. J. E. Molson said he regarded the expenditure on regional medical officers as very economical. As for research, he regretted that the department was not under the control of the Ministry of Health, and held that a great deal more money should be spent on this work.

Mr. Godfrey Locker-Lampson criticized the increases in staff salaries, more particularly in the higher secretarial grades, his point being that they went beyond scale increases.

Mr. T. Davies read a telegram from the Secretary of Joint Committees of Approved Societies, warmly supporting the appointment of regional medical officers, because a second opinion was valuable, and because any saving in benefit claims spelled economy. Taking his own experience, however, Mr. Davies added that in the country districts they were liable to miss these attentions. He said that if the Ministry of Health would send once in three weeks to the district of his society a doctor to perform such services, his society would pay £200 for the assistance. It was very difficult for one man to detect an obscure disease. Quite recently he had a case in which the doctor had certified for seven different diseases in seven weeks, and in reply to correspondence had remarked, "It is very difficult to say what is it."

Sir A. Mond, replying of high officials were fixt departments as well) by

Mr. Asquith presided. The question of voluntary hospitals and Poor Law infirmaries, and the future of their complicated system, was engaging the very earnest attention of his department. It was extremely difficult. They did not want to destroy the voluntary hospitals and make them State-aided or rate-aided institutions. The voluntary system had been a very remarkable success; but, on the other hand, there was the possibility at a future date of developing Poor Law infirmaries. These were not questions for that moment, but were being considered. The vote was then passed.

Tuberculosis Bill.

In accordance with a pledge given by Sir Alfred Mond to Dr. Raw, a new clause was added in Committee in the House of Lords to the Tuberculosis Bill, in order to meet the cases of seamen. This was brought down from the House of Lords to the Commons on May 12th.

The Treatment of Bilharziasis.—Mr. Doyle asked, on May 12th, whether the Minister for Pensions was aware that Dr. Christopherson's antimony treatment was now accepted as a certain cure for bilharziasis; that the Australian Government, after segregating all returned officers infected in Egypt, had completely stamped it out by this method of treatment; that there are still a number of men in this country who were infected during the South African war, and were still sufferers, but who were debarred from treatment by the Ministry because they had not served (in many cases because of this disease) in the recent war; and if there were any reason why an exception should not be made in favour of these men so that they might receive treatment? Mr. Macpherson sympathized with the suggestion, and said he was communicating with the War Secretary about it.

Arsenobenzol Treatment for Venereal Diseases.—Mr. R. Richardson asked the Minister of Health, on May 12th, if he would give a return of all the cases of death arising from the ill effects of the arsenobenzol treatment of venereal diseases which had been reported to his department since the commencement of the public treatment of these diseases; and if he would arrange for such particulars to be recorded in future in his annual report or in that of the chief medical officer. Sir A. Mond replied that twenty-one deaths had been reported to his department as following the administration of arsenobenzol compounds in treatment centres of venereal diseases. Further inquiries show that in three of these cases death was not due to the administration of the drug, and that in five other cases it was doubtful how far the drug had contributed to the fatal result. In the last complete year for which figures were available, the number of deaths in which the administration of the drug had been a contributing cause represented one in approximately every 4,300 patients treated for syphilis, and one in approximately every 30,000 injections of the drugs. He would consider the suggestion in the last part of the question.

"Lock-up" Surgeries.—Mr. Doyle asked, on May 12th, whether the attention of the Minister of Health had been drawn to the increasing number of what were known as lock-up medical practices, where panel medical practitioners saw panel patients at fixed hours only, as they (the doctors) had only consulting rooms there, while they resided, it might be, miles away, out of reach of a panel patient in an emergency; and whether, in view of the hardship thereby incurred by the patient, he would consider taking action. Sir A. Mond said his attention had been called to one or two cases of the kind, and they were under investigation. If Mr. Doyle was aware of any such case he would be obliged if particulars were furnished. The regulations made adequate provision for dealing with such cases.

Medical Decisions on Attributability.—Mr. Forrest asked, on May 9th, whether the Minister of Pensions was aware of the growing resentment in the country, especially among ex-service men, at what were thought to be the unfair decisions in many of those cases in which a man with a long record of good service and an A1 health certificate on entering died soon after returning to civil life, from, according to medical testimony, some ailment not connected with his war service, but of which he never showed any previous "trace" and whether steps could be taken, even if it meant some modification of the law, to meet such cases. Mr. Parker, for Mr. Macpherson, replied that he was not aware there was any feeling in the country that unfair decisions were being given. All cases were most carefully considered by experienced medical officers, and in every case where the claim was rejected on the ground that the disease was not attributable to, or aggravated by, military service the widow had a right of appeal to a tribunal which was independent of the Ministry.

Chemicals among the Key Industries.—References were made in debate in Committee of Ways and Means in the House of Commons, on May 9th, to the optical instruments and to the chemicals which are to come within the provisions of the Safeguarding of Industries Bill. The subject came up on the money resolutions which are being taken to prepare the way for the introduction of the measure after Whit Sunday. Optical glass and optical elements, microscopes and other optical instruments, thermometers, tubing and other scientific glassware, laboratory porcelain, a variety of scientific instruments and chemicals are included amongst the articles upon which an import duty amounting to 33½ per cent. is to be imposed. Sir William Pearce, in supporting the motion as a private member, referred to the report of the Balfour of Burleigh Committee and to the report of the National Health Insurance Commission, with regard to certain fine chemicals not produced in this country before the war.

The Committee on Hospital Finance.—The Committee on Hospital Finance, of which Lord Cave is chairman, has completed the taking of evidence and is now engaged on its report. The expectation is that this will be presented to the Minister of Health near the end of the month and published early in June.

Dangerous Drugs Act Regulations.—It is understood that the report of the Dangerous Drugs Act Departmental Committee is practically finished and will be available in a few days.

England and Wales.

LEEDS GENERAL INFIRMARY.

THE last few years have seen many changes at the General Infirmary at Leeds. Occurring, however, as many of them did, during the strenuous years of the great war, they have been left uncommented upon in these columns. There have been important changes in the personnel of the honorary staff; structural alterations and additions, begun before the outbreak of hostilities, have been brought to completion; a new ward pavilion with about one hundred beds has been in use for some two years, and has enabled the work to be kept up to the pre-war standard of numbers, while certain of the other wards are receiving that process of modernizing which the lapse of time has made necessary, for the infirmary was opened in the year 1868; the new theatres and out-patient rooms are now in full occupation; there has been considerable development in the x-ray department, which has been divided into two subdepartments under the care of two distinct officers, one of whom is at the head of the diagnostic section and the other at the head of the therapeutic section; the department for the treatment of venereal diseases is now fully organized, and will shortly have an addition to its staff; and the dental department of the Leeds Public Dispensary, having found the accommodation at that institution inadequate for the requirements of the growing school, has by the courtesy of the board found a temporary and very excellent habitat in the large out-patient hall which was opened in 1894, but which is now referred to as the "old" out-patient room. The nursing staff has been largely increased; a system of preliminary probationership has been instituted, and all candidates for full training at Leeds have now to undergo a three months' preliminary training; lectures are given by the honorary staff and by the university teachers, and a special tutor sister has been engaged for the work of teaching and supervising the work of the candidates at this stage of their training. These and many other matters of importance should be commented upon, not only as being of interest to former students of the Leeds school, the vast majority of whom have such cordial recollections of their clinical Alma Mater, but because the activities of a large teaching hospital must be of interest to the profession at large.

Changes in the Honorary Staff.

Dr. Churton resigned from the full staff in 1919 after nearly forty years' service, and was elected an honorary consulting physician with the right to the use of six beds. This system which prevails at Leeds was begun in the year 1884, when the rule, which of course was not made retrospective, was introduced that twenty years' service on the full staff was to be followed by promotion to the consulting staff. Under a self-denying ordinance the rule came into immediate operation by the resignation at the end of their twenty years' service on the full staff of Dr. Clifford Allbutt—as he then was—Mr. C. G. Wheelhouse and Mr. T. Pridgin Teale. For some years after his resignation Mr. Wheelhouse carried on an active professional career in Leeds, and then retired to Filey where he died a good many years ago. The activities of Sir Clifford Allbutt are known and admired by the whole profession, and many will be interested to learn that Mr. Teale gave an introductory address to the University Medical Society at the opening of one of its recent sessions, and that within the last few months he addressed the Leeds and West Riding Medico-Chirurgical Society on his favourite subject of lithotomy. The movements following on Dr. Churton's resignation created a vacancy on the assistant staff, and to this position Dr. J. Le Fleming Burrow was elected.

Mr. R. Lawford Knaggs resigned during the year 1919 from the position of honorary surgeon; he had acted on the full staff for eighteen years and was elected an honorary consulting surgeon on the recommendation of the board at a general meeting of the governors of the infirmary, who have the power to make such an appointment if they think fit, though the officer may not have acted on the full staff for the normal term of twenty years. The compliment was well merited in the case of Mr. Knaggs, whose work has always been characterized by unflagging zeal. In passing, it may be mentioned that since leaving Leeds

Mr. Knaggs has completed a very important piece of work for the Leeds school which has occupied a large amount of his time for many years. This has consisted in the complete revision of the catalogue of the bone and joint section of the pathological museum at the medical school—a work which has entailed a careful examination and remounting of most of the specimens in that section. This catalogue is shortly to be printed. The vacancy on the assistant staff brought about by Mr. Knaggs's resignation was filled by the election of Mr. Alfred Richardson to the position of assistant surgeon.

Mr. H. Secker Walker, having served his period of twenty years on the full staff in the ophthalmic department, has also been elected a consulting surgeon. Mr. Walker, to the regret of his many friends, has left Leeds for Wiltshire. Mr. Constable Hayes resigned his position on the honorary staff in 1918 and has left Leeds for Gloucestershire. The vacancies in the ophthalmic and aural departments caused by these resignations have been filled by the appointment of Mr. Harry Lee to the former and of Mr. W. Maxwell Munby to the latter department.

Dr. J. B. Hellier, who was elected obstetric physician in 1899, completed his term of service in 1919 and became honorary consulting obstetric physician, being succeeded by Mr. Carlton Oldfield. The title of this post, "obstetric physician," gives a wrong impression of the character of the work. The holder of the post is, of course, essentially a surgeon, and in future he is to be termed such. Dr. Hellier's connexion with the Leeds school has been a long and honourable one; he was a student of the school; he acted as demonstrator of anatomy; he taught materia medica and founded the museum; he lectured on gynaecology, and for many years was professor of midwifery. His interest in the school and in the welfare of the students has never flagged, and he has been unsparing of time and of effort to promote the best interests of the university and of the infirmary. He is still in full consulting work, and at the special request of the Faculty of Medicine he has consented to continue to act as honorary librarian for the joint library of the medical school and the Medico-Chirurgical Society. He is engaged, it is understood, in writing a history of the Leeds School of Medicine.

To the great regret of his friends, Professor Leyton resigned the professorship of pathology owing to ill health. The position of professor of pathology is essential to qualify anyone to act as pathologist and director of the pathological laboratory at the infirmary, and Mr. Matthew J. Stewart was appointed in succession to these two positions by the Council of the University and the Special Election Committee of the infirmary. Of the developments and future of the pathological department of the infirmary and of the university more may be said hereafter. Mr. Stewart's work as curator of the pathological and clinical laboratory at the infirmary brought him into relation with all the members of the honorary staff, and his election to the important position of professor of pathology was universally welcomed.

In connexion with a prospective and more intimate connexion between the infirmary and the school of dentistry certain temporary changes in the manner of conducting the dental work of the infirmary are being developed. Mr. Hordern, who has been honorary dental surgeon to the infirmary for a good many years, has been promoted to the consulting staff.

Death of Mr. Edward Ward.

This is not the place for any lengthy reference to the death of Mr. Edward Ward. A short obituary notice appeared in the JOURNAL of May 14th. Any reference to the changes in the personnel of the staff would, however, be very imperfect which did not express the deep regret of all who are connected with the university and with the infirmary and their sorrow in the loss of a well-loved colleague.

Statistics of the Infirmary.

In anticipation of the annual meeting of the infirmary, which is usually held in March, but which this year has been postponed till May 25th, the usual statistical tables of the numbers of patients attended to in the various departments during the year 1920 has been issued. The total number of patients treated within the walls of the infirmary as in-patients was 9,480—practically the same

as during 1919. It is of interest to note that during 1913 the number was 9,015. It has been explained above that the number of available beds has not in the meantime been increased by the opening of the new ward pavilion, and these figures may be taken as an indication that the infirmary is working, as it was in 1913, up to the limit of its resources. Of the new patients admitted 3,914 were men, 3,347 were women, and 1,500 were children. Four hundred and twenty-one patients remained in the infirmary and in the semi-convalescent hospitals on January 1st, 1920, and the balance of 293 was made up of service pensioners referred to the infirmary by the Ministry of Pensions. The average number of patients at the infirmary was 363, and at the two semi-convalescent hospitals 113. The number of new out-patients was 20,109, and of casualties 15,969. In addition there were 3,128 new cases in the venereal department. Operations were performed on 5,378 in-patients and on 3,929 out-patients.

WAR MEMORIAL AT THE LIVERPOOL MEDICAL INSTITUTION.

On May 11th, in the presence of a large number of members and ladies specially invited, a war memorial tablet, the gift of Mr. W. Thelwall Thomas, was unveiled by the Right Rev. the Lord Bishop of Liverpool, Dr. Francis Chavasse. The president, Dr. John E. Iemmell, occupied the chair, and briefly set forth the reason for commemorating in bronze those members who had paid the supreme sacrifice in their devotion to duty in the great war. In the name of the Institution he conveyed the thanks of the members to the generous donor. Mr. Thelwall Thomas, in acknowledging their appreciation, mentioned the fact that the number of members of the Institution was under 400, yet on the tablet fourteen names were inscribed who had served their country even unto death. The Lord Bishop delivered a short address before unveiling the memorial. He referred to the painful distinction conferred upon him—his son's name, Captain Noel G. Chavasse, V.C., with war is recorded—and said, "No body of men gave more of their sons and daughters to fight and work and fall than the doctors of Liverpool. We owe these men a debt of gratitude for the high ideals they set before us, and their names should ever be before us as examples of faithful service and loyalty to their country. To such we owe our deliverance from a tyranny that knew no pity and no shame."

The memorial tablet was executed by a Liverpool sculptor, Mr. Tyson Smith. It is of bronze, with the R.A.M.C. motto, "In Arduis Fidelis," inscribed on the capital. Underneath, "In honoured memory of members of the Liverpool Medical Institution who gave their lives for their country." There are fourteen names, preceded by their respective ranks, and on either side are reversed touches, with the naval and military crests of the medical service. The memorial is chaste in design and was much admired. It occupies a conspicuous position in the vestibule of the institution.

LIVERPOOL ROYAL INFIRMARY.

Mr. Robert Kennon has been appointed an honorary assistant surgeon to the Liverpool Royal Infirmary. He is M.D. of the University of Liverpool and F.R.C.S. For the past twelve years Mr. Kennon has held with distinction posts in connexion with the university. He saw active service during the war, was awarded the M.C., and was twice mentioned in dispatches.

India.

VENEREAL DISEASES' TREATMENT IN INDIA.

The League for Combating Venereal Diseases, Bombay has been in existence since March, 1917, and its work in that city is, we believe, a pioneer effort in the direction of combating venereal disease among the civil population of India. According to the third annual report of the League (1920-21) the incidence of venereal diseases in India is much higher than in England. As the provision of greater facilities for the modern treatment of venereal diseases was considered the first essential in the campaign of the

League, attention so far has been specially devoted to the dispensary which was founded, and is being conducted, under its control. From the report of the dispensary's medical officer it is evident that the work that is being done there is of a high standard, but as no more than 1,224 patients were registered during the year under report (of whom 217 were diagnosed non-venereal), only the fringe of the problem can yet have been touched in a city of the size of Bombay. The medical officer points out that the dispensary building is greatly lacking in privacy, and suggests that a general dispensary might be attached in order to induce patients to attend without having the nature of their ailment made so obvious; this recommendation is worthy of attention if a more suitable building cannot be secured. He emphasizes also the necessity for the provision in Bombay of facilities for the ante-natal and post-natal treatment of pregnant married women who have been infected by their husbands. Subsidiary centres for early treatment are also recommended in his report; irrigation stations have already been established for the daily lavage of gonorrhoea cases from the dispensary at a few municipal dispensaries in crowded parts of the city. Here again, however, the number of patients treated—84 in seven months—seems out of proportion to the work entailed. There is little doubt, therefore, that the stage of the League's campaign which is to come next—a vigorous educational propaganda—is very necessary if the population of Bombay is to benefit from the provisions which have already been made. It is intended to arrange a series of lectures in English and the vernaculars at different centres, and to distribute leaflets. A dissemination of the knowledge of the physiological laws of life, particularly among the lower classes of the population, should open their eyes to the seriousness and the grave consequences of venereal diseases. This propaganda should also create and develop a public opinion in favour of the League among all classes of society, and it is to be hoped that it may obtain the general support which it deserves, and that the campaign which it is conducting will spread throughout India.

CIVIL ASSISTANT SURGEONS

A new scale of pay for civil assistant surgeons has been announced by the Ministry of Local Self Government, subject to the limit sanctioned by the Secretary of State. The revised scale provides for pay of Rs 200 a month on first appointment, with biennial increase of Rs 25 till the eighteenth year of service. There will be grade examinations at the seventh and fourteenth years, and, at a later period, an efficiency bar is prescribed. There will be two senior grades, to which promotion will be by selection, these grades will contain four posts of Rs 425, and four posts of Rs 450. Civil assistant surgeons appointed to civil surgeoncies will draw Rs 500 by annual increments of Rs 50, and annual increments of Rs 100 for those with over five years' service to Rs 700. There will be one selection post of Rs 1,000, which will be open to officers of the Indian Medical Department and civil assistant surgeons. The new scale is to have effect from April 1st, 1920.

Correspondence.

HEART BLOCK AND THE ADAMS STOKES SYNDROME.

SIR,—At the Liverpool Medical Institution (BRITISH MEDICAL JOURNAL, May 14th, p 704) Dr. Harris expressed the opinion that in heart block the Adams Stokes syndrome signified degeneration of the heart muscle. It is very difficult to understand why this syndrome appears in some cases of heart block, but not in the majority. Yet I fear Dr. Harris's explanation may fail us. Two or three times I have had reason to believe that this explanation could not be accepted as a general rule. One case in particular seemed to be to the contrary.

An elderly gentleman in whom for some years a harsh systolic murmur had been audible at the base of the heart, began to suffer from bradycardia. A little later, when his pulse rate had fallen to 30-20 the Adams Stokes syndrome appeared. The malady increased slowly but inexorably. I often counted his ventricular pulsations as low as 12 or 10,

or even less. His own physician, the late Mr. Hyde Hills, more than once counted it at the rate of 6! The Adams-Stokes syndrome was intense, and the syncope and convulsive series were frequently repeated—often more than once in the day.

After death an aortic stenosis, evidently of very long standing, was discovered. The fibrous condensation, beginning no doubt at the aortic collar, gradually invaded the *a-v* structures. Now the heart, in obedience to the increased obstruction, had hypertrophied, and become very large and powerful. Macroscopically it appeared sound and firm; and microscopically, beyond a slight degree of fibrosis, it presented little or no defect.—I am, etc.,

Cambridge, May 14th.

CLIFFORD ALBUTT.

ECLIPSE BLINDNESS.

SIR,—I read with interest the article on eclipse blindness by Dr. Lodge, in the *BRITISH MEDICAL JOURNAL* for May 14th, and having, like I suppose most ophthalmologists, seen two similar cases following the recent eclipse, I would like to make a few comments, mainly supporting Dr. Lodge's arguments.

The first case that I saw was a girl of 18, who was led into my consulting room by the hand as though she were blind, three days after the eclipse; her history was that within a few minutes of looking at the eclipse through moderately black tinted spectacles, she had great pain in the eyes, and then "everything looked blank" when she looked at it. I found the central vision in each eye to be considerably less than 6/60, due to a large central scotoma for both white and colours; it seemed quite evident that peripheral vision was relatively unaffected, though vision was so defective that it was impossible to obtain any chart of her visual field on the perimeter. Both pupils reacted normally to light, and on dilatation with homatropine a careful examination of the fundus revealed no definite pathological appearances, beyond possibly a slight injection of both discs; a subsequent examination twelve days later still revealed no pathological changes in any part of the fundus.

This case is evidently very much more severe than either of those quoted by Dr. Lodge, and one is very uncertain as to the . . . symptoms in her case were severe, . . . back of the eyes and through the temples, which lasted for about a fortnight and had to be relieved by opiates; there was also, for the first few days, a good deal of photophobia, though no trace of redness of the anterior parts of the eyes. Dr. Lodge suggests the possibility of confusing retrolbulbar neuritis with this condition, but in this girl there was nothing to suggest it, the pupil reactions being perfectly normal and contraction well maintained when a light was kept focussed upon them; moreover, the girl appeared to be in perfect health. The actual change which takes place at the fovea is a matter of conjecture, and it is instructive to see that vision can be so profoundly affected as in this case, without there being any alteration in the retina that can be detected with the ophthalmoscope. If microscopical examination of the retina in a case of this sort could be obtained, it would no doubt throw light on the condition, but, so far as I can discover, this has never been done, owing no doubt to the difficulty in obtaining such an eye for examination.

Many ophthalmic surgeons after previous eclipses have described changes in the fundus consisting of a small yellow speck surrounded by an abnormally red appearance at the fovea in such cases—an appearance which it must be difficult to differentiate from that of a physiologically normal fundus. The two cases recently seen by myself support Dr. Lodge's contention, that there are no changes visible to the naked eye in the majority of such cases.

The symptom that Dr. Lodge describes as metamorphopsia was not present in this girl, as her vision was affected too severely for her to be able to appreciate it had it been present.

In view of these cases it certainly seems advisable, as Dr. Lodge suggests, that in future, before an eclipse, the public should be adequately warned, through the medium of the press, or in some other way, of the danger of looking at the eclipse without proper protection, tinted glasses being entirely insufficient to give such protection. If the injury to sight in such cases as the one to which I have referred is permanent it is a disaster which could and ought to be prevented in future.—I am, etc.,

Norwich, May 16th.

G. MANTON.

THE PREPARATION OF SCIENTIFIC PAPERS.

SIR,—In his letter printed in your issue of May 14th Sir James Barr is good enough to offer a series of "rules" for the guidance of writers engaged in the construction of scientific papers and in the preparation of such papers for publication. These "rules" may be accepted, I suppose, as the fruit of Sir James's considerable personal experience—in part as a contributor to medical journalism, in part as a critic, not to say a censor, of the literary efforts of others. They therefore come with a certain presumption in their favour, and the gratuitous quality of the offer adds grace to the occasion. But why is Sir James so angry with other authorities, and these not deficient in experience, who adopted at an earlier date the course he now pursues? The Medical Research Council and the *BRITISH MEDICAL JOURNAL* have each made a contribution to the end which Sir James himself is anxious to serve, and surely both the one and the other, on such a topic, have an abundant title to speak. Yet for their efforts Sir James has no larger measure of courtesy than the borrowed exclamation, "Sack the lot!" If such is the appropriate fate for advisers with whom Sir James Barr does not happen to agree, is there not some risk that he himself may fall into a similar catastrophe? The iconoclastic temper is apt to prove infectious, and, strange as it may seem to Sir James, not everyone will accept him as an instructor, even on the generous terms he proposes, for while in some respects his advice may be generally allowed, his performances do not invariably rise to the level of his precepts.

Sir James Barr not only provides "rules" for the literary aspirant, but in his criticisms of your leading article (April 23rd) he concerns himself with various questions of literary style, or at least of literary expression, and his comments may reasonably be examined in reference to his voluntary appearance as a director and guide. With his ban upon "superfluous" words, readers in general and editors in particular will doubtless be in complete accord. But is Sir James very fortunate in the example he selects? He condemns as "superfluous" the "it" in the sentence, "his [Gibbon's] notes . . . usually contained matter which he judged it becoming to veil in the decent obscurity of a dead language." Yet in an earlier paragraph he himself writes: "Why the Medical Research Council should have found it necessary to issue such instructions I cannot say." If the one "it" is superfluous, why not the other? A few lines from the judgement above recorded Sir James complains of your contributor that he writes "as if he had not got an independent opinion of his own." Critics may possibly differ as to the elegance of this phrase, but on the most liberal construction is not "got" superfluous? And would anything be lost if the words had run "as if he had not an opinion of his own"? In his specific instructions to intending authors Sir James tells us to fasten our papers with "an ordinary paper fastener," and in view of his fashion of searching criticism I feel bound to ask, is not "ordinary" superfluous? On the point here in issue Sir James gives us excellent advice, but he scarcely lives up to the height of his exhortation.

Another instruction Sir James Barr offers to the author and writer is "learn when and where to place capital letters." The advice is hortatory rather than helpful, and illustrative guidance is hardly to be found in Sir James's letter, for in his letter he writes "the Tower of Siloam," whereas both in the Authorized Version and in the Revised Version the phrase is "the tower in Siloam." Here Sir James is as unhappy with the preposition as he is with the capital letter, and this is the more remarkable seeing that for accuracy in this respect he urges a high demand. He will not suffer your contributor's phrase "a drawing should be made in Indian ink," and he insists upon the correction "with Indian ink." I wonder whether he would allow such a description as "a worker in bra and iron" or "a painter in water colours."

Really Sir James Barr would be more effective if I always practised the precision and accuracy to which invites us. He directs, for example, that when numerous corrections have been made in a typewritten article "a revised version" should be "again typed." Would a critic, following Sir James's severity, be justified in remarking that as the "revised version" has not yet been typed it is impossible at the present stage that it can be "typed again"? Finally, to complete the series, will

other guides to literary excellence warn us against the "split infinitive," Sir James gaily writes "she wished to strongly express." He thus compels the doubt whether we can afford to accept him, to the exclusion of others, as a master and exemplar in the craft of authorship. He proclaims a lofty standard and for this we owe him thanks. But his censures are not always supported by his performances.

To the classical advice, "Verify your references," Sir James naturally gives unqualified support. He tells us, indeed, that a certain discovery "necessitated me verifying the references," though, fortunately, he does not ask us to parse this phrase. Here again, however, devotion to an ideal is found to be not inconsistent with some laxity in practice. Your contributor (April 23rd) has a sentence, "he [the compositor] ought not to be put to the test." Sir James makes this read, "he ought not to be put to *that* test," and on this misquotation and "in the name of common sense" he founds an indignant protest. So true is it that even Homer sometimes nods, and that a profession of "common sense" may at times be associated with something that looks amazingly like common carelessness.

Sir James's advice to editors—a third feature of his letter—hardly concerns me, as my own editorial career, always obscure, was closed some years ago. Yet from some of his remarks I fear Sir James has found certain editorial departments not up to his standard. Happily there is one bright spot. It is provided by an American paper "to which I occasionally contribute." This paper boasts an "intellectual" editor, who, by an interesting coincidence, never "mutilates" Sir James's contributions. The inference for those who covet the complimentary adjective is an obvious one. The model editor, we are told, "should allow his ideas . . . to flow freely." Is it not an equal editorial virtue to allow Sir James's ideas to flow freely?

Those of us who aspire to be pupils rather than professors may, doubtless with advantage in some respects, take note of Sir James Barr's advice, even though, while pointing to brighter worlds, Sir James does not himself always lead the way. But we are little likely to join in a cry for the "scrapping" of editors, researchers, councils and journals in order to put Sir James Barr on the throne. These threatened authorities may remember with encouragement that Charles II lived without fear of assassination because, as he explained to his brother, "They will never kill me James to make *you* king." We had better suffer the whips of Solomon than invite the scorpions of Rehoboam. And if, in turn, the occasional contributor may venture a modest word of counsel to those who are so anxious for his improvement, it would be to remind each of these benevolent instructors of the importance of steadily supporting precept by example, "lest that by any means, when I have preached to others, I myself should be a castaway."—I am, etc.,

London, W., May 16th.

C. O. HAWTHORNE.

THE PREVENTION OF PUERPERAL INFECTION.

Sir,—In your leading article based upon Dr. Blair Bell's able paper in your issue for May 14th a matter of enormous importance to the general practitioner is raised. You lay down a standard of asepsis in midwifery which many will regard as quite impracticable. You state that in a case of normal labour no vaginal examination should be made unless absolutely unavoidable, and that in all cases the patient and the attendants should be prepared as for a major operation.

I do not say that anyone will deny this as an ideal, but I think every conservative-minded practitioner will regard it as an impossible one, and I believe a frank discussion of how far this is so to be a matter of great practical moment.

Personally I am a general practitioner who does a certain amount of midwifery, and also a fair amount of major surgery. I am quite convinced that the amount of skill and experience required in any difficult obstetric operation is fully as great, and the issue, since two lives are involved, is greater than in a large number of major surgical operations—for example, the operation for acute appendicitis. Yet I am forced (and so is everyone else under the same conditions) to perform the first operation under thoroughly bad conditions, and for absurd fees, while there is no difficulty in getting ideal conditions for the poorest person in the second operation, and where fees are involved they are adequate.

What is the chief reason for this state of affairs? It is the fact that custom and usage in connexion with obstetric operations dates back far beyond the first dawn of asepsis and far beyond the present status and organization of the profession, while that connected with major surgery has been recent and followed both. The old tradition of general practice that midwifery was the basis of it, and as a matter of business must be secured at nominal and wholly artificial fees, is the main trouble. Tradition dies hard, but the fact remains that the advent of the midwife is fast rendering this belief a mere tradition, and with the midwives lies, Sir, in my opinion, the only hope of realizing your ideal.

It is not the slightest use expecting the busy doctor to act as a good midwife. If he is doing the midwife's work he must make frequent vaginal examinations, and he certainly will put on forceps much too often to do all the other things that Dr. Blair Bell deprecates. Patients who want a doctor to act the part of a good midwife must be prepared to pay such fees as are quite out of the question for the vast majority. It is, and should be, a luxury for the rich. The first of your propositions—absence of vaginal examinations—can only be obtained by the presence of a patient and skilled person with the woman for many hours. This person is naturally the midwife. Your second proposition, that any interference with the confinement must be treated as a major operation, is much more difficult of attainment, but it is psychologically impossible to the doctor who tries to act as his own midwife. It involves education of the public and of public bodies to regard it as a major operation. Only when they put it in the same category as appendicectomy will it be possible to do it under the same conditions.

Let me conclude by tabulating my ideas of how the change can be brought about.

1. We must encourage midwives in every possible way, and we must try to raise their educational standard and their fees. Every case should be attended by a midwife, with a doctor in the background to come in if an operation is to be performed.

2. We must try and get this idea that interference is an operation more and more into our own heads and that of the public and of public bodies—that it is an operation, and that it must be paid for as an operation.

3. There is no reason whatever why every general practitioner should practise obstetrics any more than he does major surgery. What would the standard of surgical work be like if every family doctor, whether his tastes lay that way or not, were compelled by the force of public opinion to operate on his patients for all surgical emergencies? It would be far better if obstetric work were undertaken only by those who really liked it and were interested in it, working in conjunction with the midwives, and having at their disposal adequate lying-in wards at every hospital. There is only one necessity to secure this, and that is money. No small group of practitioners is going to undertake the extremely arduous task of doing practically all the serious obstetric work of a town unless it is made to pay them at least as well as it pays the small group who at present undertake the major surgery, but under these conditions I am convinced the men would be forthcoming, and the other men of the town would be only too glad to be relieved of the necessity of undertaking the midwifery to keep the family in the practice.

I fear that any real advance in this direction will remain an ideal so long as such fees are accepted as I notice in the same issue of the JOURNAL as proposed by the Scottish Board of Health. The comparison between that table of fees and Dr. Blair Bell's article is most instructive. The rule that you cannot get good work without paying for it is not to be set aside by any amount of preaching of the ideal. We must raise the whole status of the obstetric operation.—I am, etc.,

Dover, May 16th.

A. R. JORDAN, M.D., F.R.C.S.

Sir,—Again the heavy guns have opened on the general practitioner and the midwife, and we are told for the nth time that we are responsible by our negligence for the unsatisfactory results disclosed by the Registrar-General's report on maternal mortality. But our withers are unwrung, and again the result will be a tolerant smile on many of our faces, and some facetious remarks about those who have opened the bombardment. And it always

will be so until there in high places mend their ways and supply opinions gained from tested observations in place of some of the *a priori* generalizations that are usually thrown out.

It is a pity that there has grown up two techniques of midwifery—one that taught in the schools, and the other that practised on the major part of the population. But to think that the latter is due to mere carelessness is a mistake. The practitioners feel that in default of better instruction they must rely on their own observation and evolve their own technique.

The general practitioner still retains some remnants of his scientific training, and likes evidence in support of *obiter dicta*. So as one of them I should like to ask whether there is good evidence that—

1. Labours conducted as major operations are less liable to sepsis than those conducted with ordinary cleanliness?

2. Easy labours without vaginal examination are much less liable to sepsis?

3. Puerperal infection is really less prevalent in the homes of the well-to-do who are attended under so-called ideal conditions?

4. Puerperal infection is more common after such operations as simple forceps delivery or manual removal of a retained placenta than in labours ended by nature alone?

5. Infective organisms are almost always conveyed into the vagina and uterus by the attendant's hands and instruments?

Also I should like to ask:

6. Will a staphylococcus go up into the uterus on the surface of a rubber glove as easily as on a washed finger?

7. What is the exact mechanism by which a sterilized overall or a face mask prevents infection of a patient's uterus?

8. Does examination of organisms found in cases of puerperal sepsis supply any conclusive evidence of their origin, whether from the perineal skin, the skin of the attendant, materials used at the time, or from such external sources as pyorrhoea or otitis in patient or attendants?

In most cases I think the general practitioner would say that as far as his experience goes the answer to questions 1 to 5 is in the negative, but he is open to receive evidence, but not *a priori* assumptions, to the contrary.

Frankly he is puzzled by the fact that he knows he is far more aseptic than he was thirty years ago, but the figures of sepsis remain practically unchanged, and he is inclined to think that the fault may be that of his teachers, who may be chasing a will-of-the-wisp with their cry of still more asepsis, when possibly what is really required is more intelligent efforts to find out the real mechanism of infection and a new technique to meet it.

And so the big guns will boom to no effect until they show that they base their dicta on carefully verified observations, and show more respect for exact reasoning than they seem inclined to do.—I am, etc.,

Cambridge, May 15th.

C. M. STEVENSON.

SIR,—Are the methods recommended in your issue of May 14th at all practicable in dispensary and working-class practices, which must furnish a very large percentage of confinements throughout the country?

I have been in general practice two years, and, though I started with ideals quite in line with the recommendations, I find myself gradually adopting quite a different course of procedure owing to force of circumstances.

1. With reference to the application of forceps, I used to be terrified at the idea of putting on forceps to save time; now I am all in favour of getting the case over as quickly as possible owing to the pressure of other work coming along. When there is delay in the second stage caused by partial inertia, I ask myself the question: "Are you satisfied that you can deliver the woman with forceps if the injection of 1 c.cm. of pituitrin does not finish the labour in fifteen minutes?" And if I am satisfied that I can, then I give it, with so far the happiest results both for the anaesthetized patient and myself.

2. With regard to asepsis, I was amazed to find how many women were practising as maternity nurses who never used antiseptics during or after the confinement, nor

did they provide themselves with such a luxury as an enema syringe. All talk of aseptic midwifery is beside the mark so long as such persons are allowed to compete with the regular midwife.

Any attempt to instil better ideas into this class of nurse only results in your cases diminishing in number in the area where they work, and the nurse is usually engaged first and the doctor afterwards.

I am writing from the working-class end of a good London suburb, so such conditions cannot be exceptional. I do not think that there is likely to be any change in the conduct of midwifery practice and the results as regards puerperal infection till general practitioners frankly state how they conduct their maternity practice, and then, if possible, better methods of action could be decided on, having due regard to the actual difficulties of the situation.

Such an inquiry could surely be made by the British Medical Association through its Branches, and results obtained which would have a real effect on the incidence of puerperal sepsis.—I am, etc.,

May 13th.

C. M. A.

PREVENTION OF VENEREAL DISEASE.

SIR,—Lord Gorell states in his letter, which you printed in your issue of May 7th, that there is now admitted to be but one point of difference between the two societies. In order that your readers may appreciate the extent of the difference it is necessary for them to read our letter to Lord Gorell of April 22nd, which was not published in full in the BRITISH MEDICAL JOURNAL. We adhere to the position defined in that letter, and are still ready to meet the National Council for Combating Venereal Diseases according to our letter to the Bishop of Birmingham of February 25th, accepting his invitation to a round table conference, on the understanding that the National Council for Combating Venereal Diseases were prepared to take action forthwith on the terms of the report of the Bishop's committee.

The National Council for Combating Venereal Diseases did not accept this invitation, therefore the conference did not take place.—We are, etc.,

WILLOUGHBY DE BROKE,

President of the Society for the Prevention of Venereal Disease.

H. BRYAN DONKIN,

Vice-Chairman, Executive Committee, S.P.V.D.

H. WANSEY BAYLY,

Honorary Secretary, S.P.V.D.

London, W., May 13th.

Dear Lord Gorell,

I am desired by the Executive Committee of the Society for the Prevention of Venereal Disease to thank you for your letter of March 22nd, enclosing a definition of the policy of the National Council for Combating Venereal Diseases, which you tell me had been accepted by Dr. Addison.

We do not know whether Sir Alfred Mond will accept your policy as stated in the "eight points" that you sent to us, but I am afraid it is not acceptable to this Society. It appears to us to amount to nothing more than a restatement of a policy which has admittedly failed to arrest the spread of venereal infection. Indeed you admit this failure in your first point, in which you state that "the nation and the world is, in venereal disease, confronted with a terrible menace to its welfare."

I am sure you will agree with us that venereal disease is not only a formidable menace to national health, but is also a most damaging form of waste, both in men and money. We therefore submit with great respect that it is a matter of grave public concern that the National Council for Combating Venereal Diseases has still no policy to offer except a continuance of a method that has been accompanied by an alarming incidence of venereal disease at a heavy cost to the nation.

It was surely not unreasonable to expect that, after the Bishop of Birmingham's committee had endorsed the practice of immediate self-disinfection, the National Council for Combating Venereal Diseases would at least show some relaxation in their hostility to the policy of the Society for the Prevention of Venereal Disease.

Such recognition as the National Council for Combating Venereal Diseases gives to the value of immediate self-disinfection, although the term is definitely avoided in your definition, appears to us to be inconsistent. You would seem to recommend that personal cleansing immediately after incurring the risk of infection is an essential point of instruction in sex hygiene; and you advocate the public removal of any disability or misapprehension that may now exist with regard to the sale or use of disinfectants. But the practical value of this recognition is rendered nugatory by your statement that no instruction in the use of disinfectants should be officially issued, and that disinfectants in connexion with venereal diseases should not be recommended to the public.

We submit that the policy of immediate self-disinfection is either right or wrong. If it should be brought to bear tenanted in any shape or soap and water. If it is bound to use in the prevention of venereal disease, and the Ministry of Health should take in hand forthwith the necessary and simple instruction in the correct use of disinfectants by those who persist in running the risk of infection. Some knowledge of immediate self-disinfection is already public property.

We had hoped that you would admit the necessity of official instruction in this matter. We might then have joined forces for the purpose of considering the best method by which this instruction should be given. Union, therefore, is impossible unless your society definitely endorses the principle of immediate self-disinfection.

We yield to no one in our support of the moral crusade. But the moral crusade taken by itself is demonstrably inefficient. We deeply regret that the National Council for Combating Venereal Diseases has little or nothing to recommend except a vast expenditure of money for moral propaganda and an attempt to cure established disease that might have been prevented. Meanwhile venereal infection is proceeding at an alarming rate, and the policy of immediate self-disinfection involves neither delay nor money.

We propose to send this letter to the Press, together with your letter of 22nd March.

I am,
Yours very truly,
(Sgd.) WILLOUGHBY DE BROKE.

April 22nd, 1921.

REFRACTION WORK AMONG SCHOOL CHILDREN.

Sir,—Not long ago I was an applicant for a post as school medical officer and I was asked how many refraction cases I could do in an hour. Having always used both the objective as well as the subjective tests and knowing the difficulty with school children, I replied that three cases was a good average. I was at once told that at least six was expected, and I have been puzzled ever since to learn how this number could be done properly. Now I know. Mr. Bishop Harman, in his article, "The axis of astigmatism" (May 7th, p. 666), has let the secret out of the bag. They only use the objective method, they do the retinoscopy and prescribe what they consider to be appropriate spectacles from this alone. I could do six or more cases an hour by this method, but the results would be nothing comparable to those obtained from the use of subjective tests, also testing the vision by means of Snellen's types.

I was in hopes that some ophthalmic surgeon would have taken up the challenge that only objective tests are necessary in school children; but I suppose it is a delicate matter to differ from a colleague who writes in the *BRITISH MEDICAL JOURNAL* as an authority on the subject. But I appeal on behalf of school medical officers in general that we should be protected against statements of this kind, and that we should be allowed to do our work in the way we are taught at Moorfields and other eye hospitals, and give the preference always to the subjective test, using the retinoscopy only as a guide.

The use of the retinoscopy as the sole test is compulsory in infants and young children, but if it is not combined with subjective tests in older children in school clinics there will be still more cases than at present of these children coming to the hospitals to get their glasses changed.

With everything else in the article I am sure we all agree, and thank Mr. Bishop Harman for his lucidity.—I am, etc.,

ARTHUR E. LARKING, M.D., D.P.H.,
May 16th. Assistant Local School Medical Officer for Bucks.

THE EARLY DIAGNOSIS OF ACUTE ABDOMINAL AFFECTIONS.

Sir,—I hope Mr. McAdam Eccles will not think me hypercritical if I suggest that, in his comprehensive paper on the acute abdominal affections, he has done scant justice to a classical sign when, in speaking of "perforations," he says: "Better to explore than to wait for advanced signs, such as loss of liver dullness."

No doubt the surgeon pays little heed to this sign, and no abdomen is ever opened because of its presence alone, or left unopened because of its absence. But I do trust no one, for many a day, has ever waited for its development. It appeals more to the physician who desires to make the diagnosis absolute before calling in the surgeon;

and, of all the signs in medicine, I can think of none that conveys such certainty, almost such completion, of diagnosis, if it can be safely affirmed to be present; and the deduction of free gas or air in the peritoneal cavity be justifiable. It is not the loss of liver dullness that is valuable, for that is present in many other conditions; but the deduction that this loss of dullness is due to free gas within the peritoneal cavity. In making this deduction there are a number of absolute conditions to be observed. Chiefly, these are the time of its occurrence, the associated signs, and the associated general contour—size of abdomen, shape of chest, and obesity, or otherwise, of the patient. It is an early sign, and only of value when early—within the first few hours. To speak of it as a late sign is to miss its application and cultivate a dangerous fallacy. Once the abdomen has relaxed, or the least distension appeared, the sign is valueless and misleading. It may, and does, appear almost immediately after some perforations, or very shortly after; it can be noticed to have appeared between a first visit and a second visit paid a few hours later. It is essential that the abdomen be obviously rigid and retracted and more or less motionless. Its value lies solely in its association with these signs. Nor must it be trusted to in very obese people, nor in those with deep barrel-shaped chests or emphysema of the lungs. Such people may have no appreciable liver dullness at any time. But in well-shaped adolescents, thin people, or those with abdomens of natural healthy shape and size—and perforation very frequently occurs in such—its detection is easy, and if correct, and the conditions otherwise present which make deduction logical, is pathognomonic of perforation of an air-containing viscus.

Of course, it counts for nothing against perforation if the dullness of the liver is normally present. It all depends upon whether air escapes, how much and where it lodges. Usually, when the sign has been present, the practitioner may await the operation with perfect confidence. As soon as the surgeon opens the peritoneum gas audibly escapes. But in trusting to it, there must be no tympanites whatever, and there is not, in the early stages of any perforation I have ever seen. The sign may be neglected entirely; perhaps it is safer to do so in many cases. Still, it is a classical sign, and its proper significance may as well be justly stated.

I see it is twenty-five years since I first was interested in this subject, and then, as now, no little confusion surrounded its proper importance.—I am, etc.,

Glasgow, May 9th.

R. O. ADAMSON, M.D.

THE SITE OF OPERATION FOR EMPYEMA.

Sir,—I have followed with interest the discussion in your columns on "the site of operation for empyema." As during the war I was wounded in the chest, and subsequently operated on for empyema, my personal experience may be of some little value. The site chosen was in the scapular line, and I can vouch for the discomfort and even actual pain caused by the pressure of the tube when lying back in bed. I usually tried to lie on the sound side, and I know many medical men encourage this, as it is believed to cause expansion of the damaged lung. Be that as it may, it caused me considerable breathlessness and cough. Pocketing occurred three times, and it was over three months before the drainage tube was finally dispensed with.

Since return to civil life I have operated on a number of cases of empyema, and, bearing my own personal experience in mind, have always made the incision anterior to the posterior axillary line. The patients were comfortable and able to lie at ease. I have seen no pocketing and the lung appeared to expand well.

As Mr. Pearson says the particular point chosen does not matter from the point of view of drainage, may my own personal experience be counted as argument in favour of drainage anterior to the posterior axillary line? I have, of course, not forgotten that there are such things as local encysted empyemata.—I am, etc.,

May 16th.

F.R.C.S.I.

DIFFERENTIAL STAINING OF CARCINOMATA.

Sir,—Dr. Shera accuses me of haste and inexperience. I am sorry, as it does not seem to me to serve any useful purpose in controversy. In common with many laboratory workers, I have used a method indistinguishable from his

for considerably longer than his period of two years. *Pace* Dr. Shera, I was teaching histology before he was qualified, and am still in active practice as a pathologist, and I am quite content to leave the verdict to others of similar experience.

My real point, however, was not controversial, but to suggest that others without Dr. Shera's experience might be led to rely on a "differential" staining reaction rather than on the morphology of the cell itself.—I am, etc.,

London, W.C., May 13th.

A. KNYVETT GORDON, M.B.

Obituary.

SIR ROBERT WILLIAM JACKSON, C.B.,

Deputy Surgeon-General.

SIR ROBERT WILLIAM JACKSON, C.B., died at Sandymount, Dublin, on May 13th, aged 93. He was born at Edenderry, King's County, on August 11th, 1827, and was educated in Dublin. He took the L.R.C.S.I. in 1851, the L.K.Q.C.P. in 1859 and the F.R.C.S.I. in 1862. Entering the army as assistant-surgeon in the 90th Foot (Scottish Rifles) on May 26th, 1854, he attained the rank of brigade-surgeon on May 5th, 1881, and retired with a step of honorary rank on December 16th, 1882. During the regimental times he also served in the 84th Foot (York and Lancaster), 86th Foot (Royal Irish Rifles), 100th Foot (Leinster Regiment, Royal Canadians), and for several spells on the staff, and from January, 1862, to January, 1863, was on half pay.

He had a very long record of war service, first, in the Crimea (1854-55), where he was present at the siege and fall of Sevastopol and received the medal with clasp and the Turkish medal. In the Indian Mutiny (1857-1858) he was at the first relief of Lucknow, at the battle of Cawnpur, the defence of the Alambagh, the final assault and capture of Lucknow, the capture of Kalpi and the operations in Oudh; he received the medal with three clasps. He served also in the Ashanti war (1873-74), being present at the action of Essaman and relief of Abakrampra, the battles of Amoafal and Ordahsu, and the capture of Coomassie. He was mentioned in dispatches, and was awarded the medal with clasp and the C.B. In South Africa, in 1879, he was present at the operations against Sekukuni, and was again mentioned in dispatches. He was in Egypt in 1882, shared in the battle of Tel-el-Kebir, was mentioned in dispatches, and received the medal with clasp, the Khedive's bronze star, Medjidie third class and knighthood.

After his retirement he settled at Sandymount, near Dublin, where for many years he took great interest in local affairs. In 1860 he married the daughter of Mr. John Jones Simpson, who died in 1888. He married again, in 1891, the daughter of Mr. Robert P. Daye. He had one daughter and three sons, one of whom is Major R. W. H. Jackson, R.A.M.C. (retired).

THE LATE DR. C. A. GREAVES.—Dr. W. F. Dearden writes: By the passing of Dr. C. A. Greaves of Derby (of whom an obituary notice appeared in the *JOURNAL* of May 7th) the ranks of certifying factory surgeons have lost a truly great personality. His is an excellent example of how well part-time departmental service can be carried out without neglect of other professional obligations. He was a factory surgeon during the long period of fifty-two years—a unique record in itself—and it is well known among his colleagues how conscientiously and thoroughly he fulfilled the duties of his office. He was very exact and painstaking, and during the whole of this period kept a careful account of his work in factories. This regard for note-taking proved to be the salvation of the medical branch of the factory service when, in 1891, the Government sought to abolish the examinations for certificates of fitness, on the ground that certifying surgeons rarely, if ever, rejected anyone for medical reasons. Dr. Greaves was able to produce particulars of over 2,000 rejections on purely medical grounds, occurring during his twenty-three years' service, and the obnoxious clause in the bill did not survive the Committee stage. It is for this particular reason that his name will always be revered by those of his contemporaries who remember this signal service. It was not, however, his only good

work on behalf of certifying surgeons. He was a firm believer in the advantages accruing to both employers and workpeople by the exercise of medical supervision over the youthful worker, and his views were well expressed in an address contributed to the Section of Industrial Hygiene at the Manchester meeting of the British Medical Association in 1902. In the course of his remarks Dr. Greaves clearly laid down the objects to be arrived at by the surgeon in making his examination, and his classification is quoted at length in the official memorandum issued by the Home Office for the guidance of certifying surgeons. He utilized the same occasion to make some very caustic criticisms of the sixpenny fee paid for these examinations, and was very definite in his opinion that "to accept three-quarters of a chimney sweep's minimum as a proper equivalent for the performance of a medical function is surely most degrading." His method of avoiding the degradation was the establishment of a collecting-box into which the "metallic affront" was dropped for the benefit of the Children's Hospital. He resigned his appointment only twelve months ago.

COLONEL ISAAC HOYSTED, one of the rapidly dwindling list of Mutiny veterans, died suddenly at Sidcup, Kent, on May 3rd, aged 88. He was the son of the late John Hoysted, of Walterstone, county Kildare; he was educated in Dublin and at King's College, London, and took the L.R.C.S.I. in 1855; he became L.K.Q.C.P.I. in 1864, and F.R.C.S.I. in 1865. He served in the militia from May, 1855, to March, 1858, and entered the army as assistant-surgeon on March 10th, 1858, becoming surgeon-major on April 1st, 1873, and retiring with a step of honorary rank on June 20th, 1887. In the regimental days he served successively in the 80th Foot (South Staffords), 37th Foot (Hampshire), 8th Foot (King's Liverpool), 13th Foot (Prince Albert's Somerset Light Infantry), and 9th Foot (Norfolks). During the Indian Mutiny he acted as extra A.D.C. to Sir Henry Havelock at the relief of Lucknow, and in the Shahabad campaign, receiving the medal, and in the Burmese campaign of 1885-87, gaining the medal with a clasp. There seem to be now living only four survivors of the Mutiny in the A.M.D. and two in the I.M.S. In his earlier days he was a man of fine physique, great strength and activity, and a fearless rider. In 1872 he married the only daughter of Mr. James Colthurst of Cork, who died in 1879, over forty years ago. He leaves four daughters. He was a nephew of Colonel Frederick William Hoysted, who served in the American War of Independence, commanded the 59th Foot in the Peninsular, and fought at Waterloo; and a brother of the late Surgeon-General Thomas Hoysted.

DR. RICHARD WILLIAM BROGDEN died at Folkestone on May 4th, aged 67. He was born at Tockwith, near York, the son of Mr. Robert Brogden, and received his medical education at Guy's Hospital. He took the diplomas of M.R.C.S.Eng. and L.R.C.P.Lond. in 1884, and graduated M.B., B.S.Lond. in 1885. He succeeded Dr. G. Hammond in practice at Ipswich about thirty-five years ago, and was elected honorary surgeon to the East Suffolk and Ipswich Hospital in 1887, a post which he retained until he left Ipswich a year ago. He was a member of the South Suffolk Division of the British Medical Association until he removed to Folkestone. He lost his only son in the war; his wife and four daughters survive him.

THE death occurred, on May 8th, of Dr. WILLIAM HENRY ELLIS, of Bradford, at the age of 76. He was educated at Cambridge University and St. Bartholomew's Hospital, and took the diplomas of M.R.C.S.Eng. and L.S.A. in 1866. Soon afterwards he commenced practice at Shipley and remained there until his retirement in 1910. He was for many years consulting surgeon to the Saltaire Hospital, and had served as chairman of the governors of the Salt Trust and a member of the Shipley School Board. He was a member of the West Riding Bench for thirty-one years and for ten years was its chairman. He leaves four sons and two daughters, his youngest son, Captain T. M. Ellis of the West Riding Regiment, having been killed in Flanders early in 1915.

DR. LAWRENCE RAMSAY THOMSON died at Musselburgh, Midlothian, on April 2nd, aged 39. He was the elder son of Dr. A. D. R. Thomson, of Musselburgh, with whom he was working in partnership. He was educated at Edinburgh, where he graduated as M.B. and Ch.B. in 1911. He joined the R.A.M.C. as a temporary lieutenant on September 27th, 1915, and was promoted to captain after a year's service. He served at Malta during the war.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 7th the following medical degrees were conferred:

M.D.—A. T. Edwards.
M.B. B.Ch.—J. B. Hunter, W. F. H. Binks, H. Gainsborough.
M.B.—H. A. Whyte-Venables.
B.Ch.—W. N. Goldschmidt.

ERRATUM.—In the list of degrees printed in the JOURNAL of May 14th, p. 722, there was an error. The degree conferred on H. B. Dodwell was that of B.Ch., not M.Ch.

UNIVERSITY OF MANCHESTER.

THE Council has appointed Dr. Albert Ramsbottom, F.R.C.P., physician to the Manchester Royal Infirmary and lecturer on clinical medicine in the Victoria University, to be Professor of Clinical Medicine.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

THREE public lectures on "The history of chemistry in the nineteenth century," will be delivered in the Chemistry Theatre, by Sir William Tilden, F.R.S., on Fridays, May 27th, June 3rd and 10th, at 5 p.m. The chair at the first lecture will be taken by Professor J. Norman Collie, F.R.S.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN Extraordinary Comitia of the Royal College of Physicians of London was held on Thursday, May 12th, at 5 p.m., the chair being occupied by Sir Norman Moore, Bt., the President.

The following gentlemen, who were elected to the Fellowship at the last meeting, were admitted as Fellows:

C. O. Hartthorne, M.D., C. H. Melland, M.D., J. G. Emanuel, M.D., A. E. Barnes, M.B., J. P. Hedley, M.B., J. A. Torrens, M.D., A. J. Clark, M.C., M.D., A. Feilding, M.D., R. H. Steen, M.D., C. M. Wilson, M.D., G. E. S. Ward, M.D.

Diplomas in public health were granted jointly with the Royal College of Surgeons to twenty three candidates who had passed the required examinations.

Communications were received from (1) the President and Honorary Secretaries of the Section of Laryngology, Royal Society of Medicine, dated April 8th, 1921, concerning teaching and examination.

The following report, dated April 19th, was received from the Committee of Management:

The Committee of Management have received from Sir Charles Ballance, K.C.M.G., C.B., M.V.O., the visitor appointed by the Royal Colleges to inspect the examinations of the Egyptian Medical School and Hospital, Cairo, a full and interesting report on the examinations.

The following report, dated April 19th, was received from the Committee of Management:

The Committee of Management have received from Sir Charles Ballance, K.C.M.G., C.B., M.V.O., the visitor appointed by the Royal Colleges to inspect the examinations of the Egyptian Medical School and Hospital, Cairo, a full and interesting report on the examinations.

The Committee of Management have received from Sir Charles Ballance, K.C.M.G., C.B., M.V.O., the visitor appointed by the Royal Colleges to inspect the examinations of the Egyptian Medical School and Hospital, Cairo, a full and interesting report on the examinations.

The thanks of the College were accorded to Sir Charles Ballance.

The Registrar proposed an addendum to the regulation attached to By-law CXVII (which prescribes the times of the several parts of the membership examination), as follows:

"Provided that when the number of candidates renders it desirable the President and Censors may on such additional times for the clinical and oral examinations as may be required for the proper conduct of the examination."

This was resolved accordingly.

The President then dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on May 12th, when Sir Anthony Bowly, President, was in the chair.

Issue of Diplomas.—Diplomas of Membership were granted to the 103 candidates found qualified at the recent examinations;

the names were published in the report of the proceedings of the comitia of the Royal College of Physicians of London (May 7th, p. 690). Diplomas in public health were granted, jointly with the College of Physicians, to 23 candidates. Diplomas in tropical medicine were granted, jointly with the College of Physicians, to 21 candidates.

Vacancies on the Court of Examiners.—The President reported that the terms of office of Mr. R. Lawford Knaggs and Mr. J. Hutchinson as members of the Court of Examiners would expire on June 8th next, and that the vacancies thus occasioned would be filled up at the ordinary council on June 9th.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At a meeting of the President and Fellows of the Royal College of Physicians of Ireland, held in the College Hall, Kildare Street, Dublin, on May 6th, Dr. Harold Pringle, King's Professor of the Institutes of Medicine in the School of Physics, Ireland, was admitted a Fellow of the College, and Dr. Samuel Denis de Vos, of Ceylon, was admitted a Licentiate in Midwifery.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

D.P.H.—T. Pullar, Janet B. Higgins. Part I.—Ellen D. Anderson, W. Cunningham, R. J. Peters, A. Davidson, Mary C. Walker, Margaret L. Scandera, W. H. Wallace, W. D. MacKinnon, E. M. F. Curmies, A. M. Davidson, C. L. Miller, D. Heard, D. Pye, W. McAndrew, Helena E. Barrett, S. J. Henderson, J. Frew.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

FINAL PROFESSIONAL—Mary Boland, Lucretia H. H. Byrne, T. Conner, P. J. Coyne, J. C. Cusack, Edith M. L. Dodd, A. G. Fennell, P. Gahan, S. A. Gahan, J. W. E. Graham, S. J. Halpin, T. J. Kerr, J. J. McHenry, P. Moynan, J. J. O'Sullivan, J. Tolan honours.

Medical News.

THE Senate of the University of Glasgow has resolved to confer the honorary degree of Doctor of Laws (LL.D.) upon Dr. Ireland Fergus, President of the Royal Faculty of Physicians and Surgeons of Glasgow.

Dr. J. F. GASKELL, physician to Addenbrooke's Hospital, Cambridge, has been appointed honorary pathologist to the hospital in succession to Dr. Aldren Wright.

A MEETING of the School Medical Service Group of the Society of Medical Officers of Health will be held on Saturday, May 28th, at 2.15 p.m., at the School Clinic, Great Charles Street, Birmingham. Members of the School Medical Service who are not members of the society will be welcome as visitors. The honorary secretary of the group is Dr. A. Ashkenny, Soho Hall, Birmingham.

A SPECIAL course of ten lectures on advanced surgery will be given in the Surgical Unit Lecture Theatre of the London Hospital, on Tuesdays and Thursdays, at 4.15 p.m., beginning on June 7th. The course is open to post-graduates and senior students.

PROFESSOR C. S. SHERRINGTON, President of the Royal Society, and Dr. H. K. Anderson, F.R.S., Master of Gonville and Caius College, have been elected members of Athenaeum Club under Rule 2, which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

THE ordinary quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at the Mandsley Hospital, Denmark Hill, S.E., under the presidency of Dr. W. F. Menzies, on Tuesday, June 7th. Sir Frederick Mott, F.R.S., will deliver the second Mandsley lecture at 4.30 p.m.

ON May 25th Dr. C. M. Wilson will read a paper before the Royal Society of Arts on "Some effects of the war on industrial unrest," and on May 30th Sir Kenneth Goadby will read a paper on "Industrial disease and immunity." Each paper will be given at 8 p.m. at the house of the society, John Street, Adelphi, W.C.2, and discussions will follow.

TWENTY THOUSAND cases of cholera, 9,000 of which were fatal, have recently been certified in Corea.

THE Japanese Government have arranged that the principal trains leaving Tokio shall carry a medical officer.

THE Soviet Tartar Republic at Kasan has formed a medical institute with a special section for the hygiene of labour.

the patient becoming less nervous and irritable, with less palpitation and sleeping better. Of objective symptoms the tachycardia is the first to improve, and its amelioration affords the best guide in discontinuing the treatment. Since the ray will stop secretion of the normal gland, it must never be used merely to reduce the size of the gland, and its use is contraindicated for cosmetic effects, pressure symptoms, cystic degeneration and malignancy, in which cases surgery is preferable. The author concludes that x-ray therapy will take the place of surgery in the treatment of hyperthyroidism; by inhibiting cell action it produces good results without scar formation, and without the dangers attending operation.

593. The Pituitary in Graves's Disease and Myxoedema.

FRIEDMAN (*New York Med. Journ.*, March 2nd, 1921) suggests the possibility that there may be a mild overactivity of the pituitary in Graves's disease, and a mild underactivity in myxoedema. Histological changes occur in the hypophysis in Graves's disease similar to those in hyperpituitarism, and in myxoedema similar to those in hypopituitarism, pointing to some degree of hypophyseal overactivity in hyperthyroid, and of hypophyseal underactivity in hypothyroid states. Chromophilia of the anterior lobe is characteristic of Graves's disease, and chromophobia of myxoedema. The increased metabolic rate, the tendency to glycosuria, mental irritability, intestinal spasticity, tendency to miscarriages, and altered skeletal growth are some of the symptoms and signs of Graves's disease which may be in part attributable to hypophyseal overactivity, while the opposite findings in myxoedema may be due to hypophyseal underactivity. From these considerations pituitary products are contraindicated in the treatment of exophthalmic goitre, and are indicated in addition to thyroid in the treatment of myxoedema.

594. Insomnia in Children.

REH (*Rev. méd. Suisse rom.*, March, 1921) records two cases in children, aged 7 and 7½ years respectively, observed at the Geneva Children's Clinic, closely resembling those recently described by Hofstad in the Munich Children's Clinic in their symptomatology, but differing from them as regards their etiology. In the first case the symptoms appeared after an attack of influenza, while in the second case there was no previous organic affection. Hofstad's 21 cases were classified as follows in regard to their etiology: In 5 cases the symptoms occurred in children admitted to hospital with lethargic encephalitis. In 9 there was a history of influenza accompanied by drowsiness or choreiform movements which were undoubtedly examples of lethargic encephalitis. In the remaining 7 cases there was no history at all of any previous disease: but owing to the similarity of the symptoms Hofstad regarded them as an incomplete form of lethargic encephalitis. During the day the majority of the patients were psychically normal and played with their comrades, a few appeared to be reserved and shy or slightly excited. The nocturnal insomnia was characterized by retardation and diminution of sleep, which might last for weeks or months, giving rise to a state of anaemia and profound emaciation. Unlike Hofstad's cases, which at the time of publication of his paper had not shown any improvement for weeks or months, both Reh's patients recovered—one after seven months and the other after eleven months. In each case normal sleep returned after an attack of measles independently of any treatment, to which both cases had proved refractory.

595. The Diet in Typhoid Fever.

MARañÓN (*Arch. de med., cir. y espec.*, February 15th, 1921), as the result of observations on 300 cases of typhoid fever fed on mixed diet and of 1,000 on milk only, maintains that in the great majority of cases a mixed diet does not aggravate the febrile process, but rather diminishes it, and so far from increasing the frequency of complications, places the organism in an incomparably better position of nutrition than in the case of typhoid patients fed on milk only. Since a mixed diet has been adopted the emaciated type of patient has disappeared from Marañón's wards, and all his cases have maintained throughout their illness a fair state of nutrition and their convalescence has been of short duration. The diet recommended by Marañón consists of a litre of milk daily, accompanied by meat juice, yolk of eggs, biscuits and butter, boiled fish, and fruit juice. He rejects the idea that a mixed diet is more dangerous than a purely milk diet in typhoid fever. The patients take a mixed diet better, and suffer less from meteorism

than when on milk alone. Moreover, it is rare to find in these patients *post mortem* the scybala which are often caused by a milk diet.

596. Symmetrical Tuberculous Ulceration of the Labial Commissures.

BETTAZZI (*Il Policlinico*, Sez. Chir., December 15th, 1920) records a case in a man, aged 46, which presented the following features: (1) Initial leucoplasmia; (2) atypical character of the lesions; (3) development of specific ulceration of the buccal mucous membrane in an individual who had been cured some years previously of a pleuro-pulmonary affection which was almost certainly tuberculous; (4) apparent recrudescence of old tuberculous disease at the apex, probably due to a true exogenous reinfection with buccal localization. The tuberculous nature of the lesion was demonstrated by microscopical examination; the ulcer was freely excised and complete recovery took place.

SURGERY.

597. Treatment of Fractures of Spongy Bones.

NATHAN (*Amer. Journ. Med. Sciences*, April, 1921) discusses the pathology and treatment of fractures of the spongy bones. Experimentally and clinically it is found that trauma, with or without fracture, of spongy bones, or of the epiphyseal ends of long bones, induces inflammatory changes closely resembling the non-suppurative infective processes in such structures, leading to bone softening and absorption, which renders them liable to distortion when subjected to weight bearing. Such traumatic inflammation, by intra-, peri-, and para-articular induce permanent arthritic abnormalities. Though premature mobilization is harmful, fixation should not be unduly prolonged lest ankylosis result, and only experience and constant observation when and to what extent each individual case requires movement, and objective conditions, such as the relaxation of muscular spasm and subsidence of swelling, are to be relied upon in judging the course to pursue. In the upper extremity the restoration of complicated and highly specialized movements is the therapeutic aim, while in the lower extremity weight bearing is a more important function than complete joint movement. Severe trauma to the back requires rest in bed or immobilization immediately after injury, even when the objective signs are negative, because of the tendency for subsequent decalcification and bone absorption to come on gradually and not until some time after the injury. In serious cases immobilization with plaster or a back brace must be continuous. In fractures near the joints of the lower extremity, provided the fragments are held in apposition, immobilization with early locomotion promises the earliest and surest results, but traumas of the tarsus resemble those of the spine in that the tendency to arthritis and distortion sometimes continues for a long time after injury. Long-continued supervision is required, and a support—such as a modification of the Whitman plate—to prevent valgus, should be worn for some months.

598. Surgical Treatment of Tuberculosis of the Bones and Joints.

CHIEVITZ (*Hospitalstidende*, March 2nd, 1921) has investigated the after-histories of 233 cases of surgical tuberculosis treated at Professor Rovsing's hospital on surgical lines, ranging from immobilization to resection. The observation period was from six to sixteen years. He tabulates his results according to the site of the disease. In 40 cases of hip disease there were 11 deaths, all within the first year of treatment. Of 14 of these cases discharged with fistulae 8 had subsequently healed. Though it usually took several years for the patient to regain his working capacity, the author expresses amazement at the permanency of the cures ultimately effected. A study of the 65 cases of disease of the knee brought out the point that resection quickly restores the patient's capacity for work; this was achieved by 21 patients within six months of the operation. Of the 14 deaths in this class, 10 occurred within the first two years of treatment. In every class of case the mortality was practically confined to the first year or two; after this interval the mortality from tuberculosis was almost negligible. The author also found that, though new clinical manifestations of tuberculosis might be separated by an interval of several months, they yet represented one and the same process in most cases. This view that the different manifestations originated at the same time, although they became clinically demonstrable

at different times, was supported by the observation that in 16 out of 22 cases of multiple foot the new manifestations occurred within a period of only one year.

599. Extraction Operation for Varicose Veins

COLT (*Brit. Journ. Surg.*, April, 1921) reports the late results in twenty cases of Babcock's extraction operation for varicose veins. It is the operation of choice for most cases, especially early ones in which the internal saphenous vein is involved. A general anaesthetic is advisable when numerous other veins and adjacent tributaries have to be ligated, divided or excised, though local infiltration with 0.25 per cent novocain over the sites of incision may often suffice. With the patient in slight Trendelenburg position it is important to tie and divide the saphena close to the saphenous opening in order to ensure extraction of the upper ends of the internal and external femoral cutaneous branches. A difficulty sometimes experienced is getting the knob of the extractor to pass a valve in the lower third of the thigh, probably due to the presence of a small tributary communicating with the deep veins four inches above the patella. Less bruising occurs when the extraction is made upwards instead of downwards, probably because the tributaries break without being displaced through an angle before they rupture. The operation results in the removal—in twelve minutes—of the whole of the internal saphenous vein, with about three inches of each of its tributaries, through two small incisions. Combined with local excision of all the tributary junctions of the external and internal saphenous systems the operation is the best one for ordinary cases if the symptoms are to be relieved for long periods. The need for an investigation by a plethysmographic method of the relationship between symptoms and the carrying capacity and retarding effects of the superficial and deep veins is urged, as also for further information as to the frequency with which duplication of the internal saphenous vein occurs.

600 Cysts in the Semilunar Cartilages

OLLERENSHAW (*Brit. Journ. Surg.*, April, 1921) discusses the development of cysts in connexion with the external semilunar cartilage of the knee joint, having personal experience of three cases. Clinically there is a history of injury, not necessarily severe, with gradually increasing pain and lameness, and the development of a rounded swelling over the external cartilage at the junction of its anterior and middle thirds. Varying in size from half an inch to an inch in diameter, the swelling is tense, fluctuant, and contains a clear glycerin-like fluid. The cysts are considered to be developmental in origin, due to small endothelial inclusions in the cartilage, the trauma causing irritation and distension of the spaces. The lesion in all the recorded cases has been in the external cartilage, no instance of its occurrence in the internal cartilage having yet been reported. Treatment consists in complete removal of the whole of the cyst-bearing cartilage with the cysts intact, since local removal of the cyst alone is frequently followed by recurrence. The after progress of the author's three cases, in which complete removal with the cysts intact was performed, was uneventful, all recovering with full function and freedom from any discomfort.

601 Rectal Injection of Massive Doses of Neo-arsphenamin

MEHRTE'S (*Journ. Amer. Med. Assoc.*, February 26th, 1921), considering that in previous investigations upon the value of rectal injections of neo-arsphenamin too small doses were used, conducted experiments by gradually increasing the dose per rectum up to 4 grams of neo-arsphenamin. A bulk purge was administered the day before, and two hours before treatment the colon was flushed until the washings returned clear. Simultaneously with the injection opium was given orally or hypodermically. After dissolving and neutralizing the neo-arsphenamin in the usual way, 100 c.c. were injected and retained, if possible, for twenty-four hours, the blood, urine, and spinal fluid being analysed for arsenic content. 160 injections were given before the maximum dose of 4 grams was reached, this dose being given in 125 cases with complete safety. It was found that arsenic was absorbed into and remained longer in the blood, and that larger quantities were eliminated in the urine, than after intravenous injections, while about equal concentrations in the spinal fluid were obtained with either method. Although intravenous administration is still the method of choice in most cases, rectal administration in massive doses is useful, especially in children, in those with difficult veins, and in those for whom intravenous injections are dangerous or undesirable.

602.

Surgical Narcosis

GOVARTS (*Le Schiphol*, March 12th, 1921) speaks very favourably of a method of procuring anaesthesia, described by Clerc Dandoy. An hour and a quarter before operation the patient is given a hypodermic mixture of dionin, heroin, morphine, and hyosine hydrobromate. To produce narcosis a mixture of one part chloroform, one part ether, and half a part ethyl chloride is given. An attempt is made to show how each of the various drugs plays a part. The advantages claimed for the method are greater safety, satisfactory anaesthesia, and diminished toxic results.

OBSTETRICS AND GYNAECOLOGY.

603 Gabaston's Method for Removal of the Placenta.

ESMANN (*Hospitalstunde*, March 16th, 1921) has nothing but good to say of Gabaston's method, which consists of injecting sterile saline solution into the placenta through the umbilical vein. In the course of only a couple of weeks the author encountered four cases of adherent placenta in which this method was perfectly successful, although Ciede's method had been tried and had failed. In the first case the injection of only 400 c.c. of sterile water was sufficient. In the second the placenta was not expelled until about 1,000 c.c. had been injected, and in the last two cases about 800 c.c. were injected. One of the patients was a 3 para, aged 30, whose last confinement in her home three years earlier had been complicated by retention of the placenta. Manual detachment had been undertaken, fever had supervened with bilateral phlebitis, and she had been confined to bed for five months. The author was therefore anxious to avoid a repetition of this misfortune. The patient had a severe cold on admission to hospital, and for some days she was febrile and showed signs of small infarcts of the lungs. But the author regards this condition as being unconnected with the adoption of Gabaston's method, and the patient was discharged in good health after confinement to bed for about three weeks. The remaining three patients were primiparae, in two cases labour was completed spontaneously, in the third it had to be hastened with forceps on account of imminent asphyxia. The puerperium in all these cases was uneventful.

604 Delivery by Version in Normal Labour

POTTER, in a paper read to the Philadelphia Obstetrical Society (*Amer. Journ. of Obstet. and Gynec.*, March, 1921), advocates the version and delivery as a breech in all normal confinements. He believes that by this unorthodox procedure he relieves the patient of much pain, and diminishes the risks of laceration and infections. In one year he performed 920 versions, 400 being primiparae, 520 multiparae, out of 1,113 deliveries. In this number there were 41 stillborn infants and 34 children died in the hospital. The maternal mortality was two—one from colitis and one from pneumonia. In the discussion that followed, opinion varied greatly as to whether it was justifiable to teach version as a routine, but all agreed that in Potter's hands the results were as good as those obtained by any other method of delivery.

605 Opoththerapy and the Menopause

MARIE and FOUCREYD (*Bull. Soc. de Ther.*, March 9th, 1921) remark that every alienist knows how dangerous the menopause is in neuropsychic subjects as well as in women with renal or hepatic insufficiency. Obsessions, phobias, melancholia, acute hallucinatory confusion, and more or less systematized persecutory insanity are frequently observed in the period preceding, accompanying, and following the menopause. Marie and Foucreyde are convinced that the suppression of the menstrual flow is not responsible for these symptoms, but assign the chief part to a deficiency of the endocrine glands, especially of the thyro-ovarian secretion, as maintained by Hutinel. They have therefore made a systematic use of opoththerapy in all the mental disorders of the menopause. After a preliminary period devoted to a disinfection of the system, when, as is the rule, a slight hepato-renal insufficiency exists, opoththerapy is instituted, consisting in all cases of thyroid and ovarian extract and supplemented by suprarenal extract or extracts of other endocrine glands in the presence of symptoms indicating their insufficiency. The histories of 8 cases are recorded, in 6 of which considerable improvement occurred, and in 2 no result was obtained from this treatment.

606. **Obstetric Paralysis of the Arm.**

MARAGLIANO (*La Chirurgia degli organi di Movimento*, February, 1921) controverts the views of the authors who have suggested that obstetric palsy may be caused by a lesion of the capsule of the shoulder-joint, apart from any muscular or nervous injury; the articular swelling, he believes, is a symptom of the distortion, and is always associated with lesions of the brachial plexus. In some cases muscular defects of the biceps, coraco-brachialis or brachialis anticus, are concerned in the deformity. It is never too late, Maragliano believes, to obtain some degree of improvement in the condition, however long it may have been untreated. The essential requisite is correction or hypercorrection of the deformity, with hyperabduction and external rotation at the shoulder, flexion at the elbow, and extension of the wrist, hand, and fingers. During the first few months of life an apparatus should be used which can be removed at frequent intervals for purposes of massage and toilet; in older patients the limb should be continuously immobilized for as long as twelve months.

607. **Fibromyoma of the Urethra.**

ACCORDING to OTTOW (*Zentralbl. f. Gynäk.*, March 12th, 1921) fibroid tumours of the female urethra are very rare, and Palm in 1901 was able to collect only 21 cases of fibroma, 4 of fibromyoma, and one of myoma. Ottow encountered a case of pediculated fibromyoma of the urethra in a multipara aged 53, who complained of a recently noticed discharge, but in whom micturition was normally performed. A hard, egg-shaped tumour, 2.7 by 2.4 by 1.8 cm., presented in front of a greatly dilated external urinary orifice; the surface of the tumour was smooth except for a narrow band of corrugations which extended sagittally over its anterior surface from the neighbourhood of the clitoris to that of the vagina. The broad pedicle, 1 cm. broad, sprang from the anterior wall of the urethra.

608. **Rupture of Uterus Treated Expectantly.**

VEXOT and PÉRY (*La Gynéc.*, January, 1921) record the case of a woman in whom, after extraction of the foetus, a tear admitting three fingers was found in the uterus. The treatment was expectant. Few signs of shock were perceptible, and the sequelae were in every way satisfactory. ANDÉRODIAS (*Ibid.*) has had a similar experience. The authors are agreed, however, in recommending laparotomy, whenever possible, as the correct treatment for rupture.

PATHOLOGY.

609. **Sedimentation Velocity of Erythrocytes during Pregnancy.**

ACCORDING to MACCABRUNI (*Ann. di Ostetricia e Gynecol.*, January, 1921), Fähræus in 1916 first noted that sedimentation of red blood cells in citrated blood occurred more rapidly in blood derived from pregnant women; the sedimentation velocity, he found, increased progressively as pregnancy advanced, and at term had become increased fourfold. The rapidity of sedimentation became increased also in certain infections and in some cases of tumour. In 1920 Linzenmeier confirmed these observations, and found that the increased velocity of sedimentation was not present before the fourth month of gestation; apart from pregnancy the phenomenon was particularly well marked in cases of pelvic cellulitis or peritonitis and of adnexal inflammations. It was also established that the diminution of sedimentation time persisted for eight months *post partum*. It is now acknowledged that the phenomenon has little diagnostic value; it is not present in the early months of pregnancy, and is of no assistance in the diagnosis between ectopic gestation and adnexal inflammations. Maccabruni claims to have discovered the cause of the sedimentation phenomenon by investigation of the corresponding specific gravity indices of the plasma. Whether taken from pregnant or non-pregnant subjects, from healthy women or from those who are the subject of various morbid processes (pelvic or located elsewhere), the red blood cells, provided they have been centrifugalized and washed in normal saline solution, exhibit exactly similar velocities of sedimentation. The cause of Fähræus's phenomenon is therefore to be found in the plasma. Further experiments showed that the variations of sedimentation velocity corresponded invariably to variations (in the inverse sense) of the specific gravity of the blood plasma. The author acknowledges that experimental alterations in the saline content, and therefore the specific gravity of the plasma, did not lead to corresponding

inverse alterations of sedimentation time, but points out that in such experiments haemolytic factors come into play. Support for his view is to be found in Zangemeister's researches in connexion with hydraemia gravidarum, and Tridonani's finding of a constant reduction in the specific gravity of the blood serum during pregnancy.

610. **Sarcoma of the Stomach.**

ACCORDING to KLINKERT (*Nederl. Tijdschr. v. Geneesk.*, April 2nd, 1921), who records a case in a man aged 28, sarcoma of the stomach is a rare occurrence; only one case being met with to every 200 gastric carcinomata. Haggard in 1920 collected 244 cases of gastric sarcoma, of which 107 came to operation. Two forms of gastric sarcoma are described. The first, of which Klinkert's case is an example, shows a tendency to infiltration, the whole stomach wall being invaded by the new growth. Tumours of this kind are almost always lymphosarcoma or round-celled sarcoma. They arise from the submucosa and do not involve the mucous membrane until late. This explains why haemorrhages do not occur till late, in contrast with carcinoma, which, being a malignant growth of the mucous membrane, is associated with occult haemorrhage. Symptoms of pyloric stenosis are rare in gastric sarcoma, although they happened to occur in Klinkert's case. Round-celled or lymphosarcoma of the stomach usually occurs in young persons. The prognosis is grave, even after operation, as metastasis occurs, according to Flebbe, in 40 per cent. of the cases, especially in the lymphatic glands and liver. Cases of complete recovery, however, have been recorded, and Rupert reports a case in which the patient was alive seven years after the onset. The second form of gastric sarcoma is fibrosarcoma and usually occurs late in life and is more

It may form a very large tumour, which is attached only by a pedicle to the stomach wall and is liable to cause great difficulty in diagnosis, as it has been mistaken for an ovarian cyst. The prognosis is much more favourable in these cases, complete recovery taking place in 70 per cent. according to Flebbe.

611. **Primary Hypertension.**

PAL (*Wien. klin. Woch.*, February 10th, 1921) distinguishes a primary permanent hypertension, due to a hypertonic condition of the muscular wall of the arteries, from secondary hypertension, which is found in certain forms of nephritis and arterio-sclerosis. The mitral stage of primary hypertension is almost always free from symptoms. The heart is usually already considerably enlarged when subjective symptoms occur, such as headache, irritability, and insomnia. The etiology of the condition is unknown, but most probably there is a familial predisposition.

612. **Cysts of the Anterior Mediastinum.**

ACCORDING to CLERC and DUVAL (*Bull. et Mém. Soc. de Chir.*, February 15th, 1921), who record a case in which the tumour was successfully removed by the transpleural route, dermoid cysts of the anterior mediastinum may be classified as follows: (1) Retrosternal, (2) cervico-retrosternal, (3) median and lateral mediastino-thoracic, (4) lateral thoracic. Of 51 cases collected by Naudrot, 3 cysts were situated in the mediastinum and projected into one-half of the thorax, 6 were cervico-mediastinal, 18 did not extend beyond the limits of the anterior mediastinum and 24 which had mainly developed in one side of the thorax projected into the pleural cavity. From the surgical point of view, therefore, the two following varieties of cysts can be distinguished: (1) Those which can be attacked by the anterior mediastinal route only, the incision being prolonged upwards to the neck, if necessary; (2) those which can be attacked by the co-tal route the most frequent variety.

613. **Histological Examination of the Skin after Subcutaneous Injections of Paraffin.**

VAN GELDEREN (*Nederl. Tijdschr. v. Geneesk.*, February 19th, 1921) made a histological examination of the skin of a dog which had been given eight injections of liquid paraffin, with the following results: (1) The paraffin is absorbed by phagocytes. The vacuolated cells round the deposits of paraffin are leucocytes and fibroblasts which have undergone fatty degeneration. (2) A slight inflammatory reaction occurs in the neighbourhood of the paraffin, with considerable degeneration of connective tissue. (3) Encapsulation begins in the second week. A slight infiltration of small cells persists. Giant cells are absent. (4) Paraffin exerts a permanent irritation of the cells of the body, as is shown by fatty degeneration and the marked growth of fibroblasts.

Iodolysin

IN RHEUMATISM &

RHEUMATOID

ARTHRITIS

'Iodolysin' is a soluble compound of Thiosinamin with Iodine and contains 43 per cent. Thiosinamin and 47 per cent. of Iodine. The preparation has been very successfully used in the treatment of Rheumatoid Arthritis and Arthritis Deformans.

A Striking Report

"It may interest you to know that I have been using it ('Kapsol' 'Iodolysin') in a case of Rheumatoid Arthritis with very marked success. I saw the case first about a year ago when she had been a complete cripple for over six months. She was discharged from a hospital in ——— as incurable. I found her suffering from *pyorrhœa alveolaris*, which I treated with an auto-vaccine and afterwards gave her the 'Iodolysin', and that only, in varying doses. She can now walk into her garden, goes up and down stairs, dresses her own hair, and her joints are quite free from pain and deformity. She continues to take one 'Kapsol' daily. I think the result is most satisfactory."

Bronchial Affections

Quinsy—Pharyngitis—Laryngitis—Influenza

are usually more prevalent during the "breaking-up" season, following the Winter months.

applied thick and hot over the throat and upper air passages, not only gives almost instant comfort to the patient but begins promptly to reduce and relieve the inflammatory process in the larynx and bronchi.

FOSFOXYL

Assimilable Phosphorus

STIMULANT AND TONIC.

SPECIFIC FOR MENTAL AND NERVOUS DEPRESSION.

Fosfoxyl acts as a powerful stimulant of the central nervous system and promotes mental activity; its specific action in melancholia and neurasthenia is due to its property of elevating the nerve tone.

Fosfoxyl is an excitant of assimilation and at the same time of appetite, hence its action in anæmia, rachitism, and rheumatism.

Fosfoxyl is a corrective in mal-assimilation; hence its use in phosphaturia, tuberculosis, and diabetes.

In Bottles containing 155 c.c.

IODEYL

AN ORGANIC COMBINATION OF IODINE AND PURE PEPTONE.

Iodeyl possesses a special affinity for those organs containing lymphoidal elements. It is a special treatment of the lymphoidal tissues, and is therefore useful in cases of lymphatism and scrofula.

Iodeyl advantageously replaces iodide of potassium in all cases where this is used as an anti syphilitic, without causing iodism.

Iodeyl is an excellent resolvent for goitre.

In Bottles containing 60 Globules.

A Clinical Study OF THREE CASES OF HEART-BLOCK.

BY
T. WARDROP GRIFFITH, C.M.G., M.D., F.R.C.P.,
PROFESSOR OF MEDICINE, UNIVERSITY OF LEEDS; HONORARY
PHYSICIAN, GENERAL INFIRMARY AT LEEDS.

THE three cases of heart block which form the subject of this communication present certain features of interest. In the first, a block which remained complete for a long period suddenly broke into a two to one block and ultimately passed off altogether. In the second case, though the vexed and difficult question of whether the block was partial or complete arose from time to time, there certainly were periods when the block was of the former character, and it was mainly during these that the tracings I discuss here were taken. The phenomenon of ventricular "escape" is shown; an auscultatory sign is mentioned to which I have elsewhere referred; the effects of amyl nitrite and of atropine are discussed, and tracings are shown which demonstrate the occasional occurrence of "flutter" of the auricle. The third case is put on record not only as an example of complete heart-block with an unusually slow ventricular rhythm, but on account of the large number of attacks of the Adams-Stokes character, during some of which satisfactory tracings were obtained. In this case also, simultaneous tracings of the pulse and of the respiration showed a remarkable relation between the periods of asystole and those of the apnoeic phases of the Cheyne-Stokes respiration when that was present.

CASE I.

W. R., aged 60, a gardener, was admitted under the care of my colleague, Dr. Watson, to whom I was indebted for permission to study the case and who has also kindly allowed me to publish the results of my investigations. Four months before admission he felt giddy when at work; this feeling was transient, but recurred in a fortnight and then almost every day. He became very conscious of the beating of his heart and volunteered the information that its action had become very infrequent. He was a temperate man and moderate in the use of tobacco. He had had rheumatic fever when he was 38 years of age; there was no evidence of syphilis. His complaint was of some measure of breathlessness and of a feeling of oppression over the heart. The arterial walls were thickened; the apex beat was forcible and it was external to the nipple line; a systolic bruit was audible with its maximum at the apex and was also heard at the aortic and pulmonary areas, but there was no clear evidence of a valvular lesion. The pulse was regular and infrequent; from the date of his admission till the twenty-eighth day of his stay in hospital the pulse never exceeded 36, and it was counted as low as 24. On the twenty-eighth day of his stay in hospital he detected a change in the frequency of the heart's action. On counting the pulse he found it was 48; shortly before he had counted it at 24, and his report at a later period of the same day was that "it was running backwards and forwards from 44 to 63 and 70 and upwards, but was never keeping to one regular beat."

The tracings shown in Figs. 1 to 5 were taken on the same day during the former of these two phases. The

FIG. 1.

upper tracing of Fig. 1 might readily be interpreted as an example of a partial block in which every third auricular stimulus passes to the ventricle. The lower

tracing, taken by itself, might also bear that interpretation, though an undoubted lengthening out of the a-c interval as the tracing is read from left to right ought to arouse one's suspicions of the block being a complete one. When, however, the upper and lower tracings are viewed in relation to one another, the evidence in favour of the block being a complete one is very strong. The a-c interval is much longer in the lower than in the upper tracing, and a partial block would not account for this. On the other hand, if the block were a complete one it is clear that a temporary acceleration of the auricular rate would result in this interval being lengthened. The diagram in Fig. 2 explains this.

FIG. 2.

I have elsewhere¹ discussed the difficulties, sometimes I believe insuperable, which await the attempt to distinguish between a partial and a complete auriculo-ventricular block. In this case it is not a difficult task. If, in any case where the question arises of there being a two to one or a three to one heart-block, a long tracing is taken, and it is found that variations in the frequency of the auricular contractions are slavishly followed by similar variations in the ventricular rate, this will be accepted as confirming the partial nature of the block. If, on the other hand, in spite of variations in the auricular rate, the ventricle goes on the even tenor of its way and beats with perfect regularity, we may regard the block as being complete. It is true that in cases of complete block there is nothing to prevent the auricular rate happening to be exactly twice or three times that of the ventricular rate, but the arm of coincidence would require to be a very long one for this relationship not to vary in a tracing taken over a period of many minutes. Still I have seen it occur, and it is sometimes a good plan to get the patient gently to inhale some ammonia, which has the effect of increasing the auricular rate. Light may thus be thrown on the relationship between the auricular and ventricular contractions. Fig. 3 shows the result of this

FIG. 3.

experiment. At a time when the auricle was beating exactly three times the rate of the ventricle, the patient was directed to inhale a little ammonia. For some time, but only for the period of a few beats, the auricle went on beating at the same rate; then the beats became rather more frequent. As it was observed that the ventricular rate was not affected in the slightest degree, confirmation was obtained of the complete character of the block. In the upper tracing of Fig. 3 it will be seen that every third auricular wave—and this I have underlined—"falls back" from the "c" which comes after it, and in this way the seven radial periods between the two asterisks are equal to twenty-one and a half interauricular periods. With the increase in auricular rate in the lower tracing it is seen that seven radial periods correspond to twenty-two interauricular periods. Throughout, the ventricle beats with remarkable regularity.

But in this case the completeness of the block was obvious without artificial means. Later in the day the

tracing shown in Fig. 4 was obtained. The block is manifestly a complete one, and it will be seen that at every fourth cycle auricle and ventricle contract at the

FIG. 4.

same moment. While this relationship prevailed a tracing was taken over the apex beat, and this is shown in Fig. 5. The position of some of the auricular waves is open to doubt, but in the case of the second and sixth ventricular

FIG. 5.

impulses it is clear that the systolic plateau is dimpled by the drag of the contracting auricle, while in the case of the third and seventh the end of the plateau is modified. Some may see a difficulty in accepting the view that the plateau of a powerfully contracting ventricle can be dimpled by the action of the auricle, but this dimpling of the plateau does not represent any victory of the auricle over the ventricle. Here there is no question of which is the stronger; the greater part of the ventricular force is engaged in driving blood into the aorta, a small part of it only in maintaining the forward thrust of the apex. This contracting ventricle is drawn back as a whole from the chest wall by the drag of the auricle in systole.

The sudden increase in the pulse rate noticed by the patient on the twenty-eighth day of his stay in hospital has been mentioned; for about thirty-six hours the rate varied from about 36 to 68 or 70. On the day on which the alteration in rate was observed the tracing shown in Fig. 6 was obtained. Calculated from the slow rhythm

FIG. 6.

the pulse rate is seen to be about 36 per minute. If the condition is still one of complete block, we must regard the fifth pulse wave as the expression of an extra-systole of the kind described by Wenckebach in complete heart-block; and this view would be strengthened by there being no lengthening of the *a-c* interval which leads to this fifth systole as might be expected if two auricular stimuli got through in succession, as well as by the next radial period being practically equal to the customary long radial intervals. Still I incline to think that the condition is really one of a two to one heart-block with the occasional passage of two auricular stimuli in succession, and this

FIG. 7.

appears to be borne out by the two tracings which I took the following day. Figure 7 shows what I take to be a change from a two to one rhythm to one in which every auricular stimulus passes to the ventricle. Calculated on the slow rate the pulse is about 36; when every stimulus

gets through the auricular rate very soon falls slightly, and this is reflected in the rate of the ventricle, for towards the end of the tracing it will be seen that the time

FIG. 8.

occupied by two radial periods is rather greater than that occupied by one period of the slow rate. Figure 8 shows the converse of this—a change, that is to say, from the fast rhythm to the slow. Here it is to be observed that shortly after the blocking of every second stimulus from the auricle, the auricular rate increases. I think that in these variations we may see an expression, though at first sight not perhaps a very obvious one, of the well known relationship between the blood pressure in the medulla and the frequency of the cardiac action. When the blood pressure rises the cardiac systoles are lessened in number by vagus influence; when it falls, the removal of that influence leads to their increase. This influence of the vagus is of course exercised primarily on the auricle, and it is the rhythm of this chamber which must be studied in this connexion. In Fig. 7 the sudden increase in the number of systoles due to the passing of the block will tend to raise the blood pressure; this in turn will lead to a slowing of the auricle, which will result in two radial pulse periods of the rapid phase being slightly greater than one of the slow phase. So also in Fig. 8 the blocking of auricular stimuli after the middle of the tracing will primarily tend to lower arterial blood pressure, and the quickening up of the auricle which soon follows may be regarded as being the result of this, and also an adaptive effort to combat the lowering of pressure.

Two days afterwards the condition was that shown in Fig. 9. Every auricular stimulus passes through, but there remains some lengthening of the *a-c* interval. There was no recurrence, and the man went home after a few days of this normal rhythm. I heard from his

FIG. 9.

medical man some time afterwards that he had again had an infrequent pulse for some three weeks; that this suddenly passed off, the pulse rising to 120 and then in ten minutes falling to 80. He died some months after this without any obvious cardiac symptoms, and I understand that he had abdominal discomfort and emaciation.

CASE II.

A woman of about 38, who was admitted under my care complaining of dyspnoea and who was conscious of the cardiac action. The systolic blood pressure was 250 mm. of mercury and sometimes higher, and there was a trace of albumin in the urine. The pulse was infrequent, sometimes regular and sometimes irregular. The degree of irregularity was sometimes enough to strike one at once, and on some occasions was so slight that it could not be detected without instrumental means.

The first tracing which I show from this patient (Fig. 10) reveals an impairment of conductivity, for not only every second auricular stimulus is blocked, but the passage of those which reach the ventricle is delayed. I find it often an advantage to measure from the summit of the "a" wave to the radial rise in estimating conductivity rather than to adopt the usual measurement from the beginning of the auricular wave to the beginning of the carotid. For reasons which I need not mention here the beginnings of both these waves may be obscured. It is clear that the block is not a complete one and that the auricular rate is dominating the ventricle. In the

place the ventricular rate is 47, which is high for a complete block, and in the second place the relationship which is shown in the figure between auricle and ventricle was preserved over a long tracing.

FIG. 10.

In the next tracing (Fig. 11) the auricle is beating less frequently—that is to say, at 54 and not at 94 a minute. At the time this tracing was made most of the auricular stimuli got through in spite of the fact that some of them were premature, a condition inimical to transmission; but

FIG. 11.

at one point it will be seen that a contraction of the auricle has indeed failed to reach the ventricle, probably because it is more premature than the others which are only associated with an increase in the a-c interval. With the auricle beating at 54 instead of at 94 the blocking of one stimulus from the auricle will give the ventricle a much longer time in which to build up its stimulus material to the flash point, and this is more than enough, for its systole occurs eight fifths of a second after the previous beat—that is, as it so happens, at the same time as the auricle contracts, and of course at a time that it cannot be attributed to this event. This phenomenon is not uncommon in cases of partial block and is by Einthoven referred to as "ventricular escape."

The next tracing (Fig. 12) shows the blocking of stimuli becoming rhythmical. One of these is premature. The

FIG. 12.

escaped ventricular contraction occurs synchronously with the auricular contraction, and this gave rise to an alteration in the first sound of the heart. There was usually a faint systolic bruit at the apex, but when in consequence of ventricular escape auricle and ventricle contracted at the same time the first sound became loud and thumping and the bruit was not audible. When in a case of infrequent cardiac action the first sound shows this alteration, either rhythmically or irregularly, one may strongly suspect either a partial block with escape of the ventricle or a condition of complete block. The black dots under the radial tracing indicate beats which were announced as being loud by an observer who was confining his attention to that one point. He did not give his signal, however, at one point when the two cavities contracted together, and this I have indicated by a small circle.

Effect of Amyl Nitrite.

As I had found that inhalation of amyl nitrite caused a partial block to be overcome, I decided to make the test in this case, but on examining the patient before doing so I found the heart so nearly regular that I was unable to make out the slight irregularity which existed without

instrumental means. I also found that the characters of the pulse in the veins of the neck had entirely changed (see Fig. 13). The waves referable to the auricle were now 266 per minute, while the ventricle was beating so

FIG. 13.

infrequently that the pulse was about 46 and the radial spaces varied from about six to seven fifths of a second. The condition was clearly that known as "flutter," and for reasons I need not mention at present I am in some doubt whether the block was a complete or a partial one. Inhalation of amyl nitrite did not at first produce any effect on the auricle, which continued to give rise to 266 waves per minute. The radial pulse increased to 55 (see Fig. 14). If the block was a partial one this might

FIG. 14.

be due to auricular impulses, getting through more frequently from the improvement in conductivity which occurs from amyl nitrite; if, on the other hand, the block was a complete one, the action on the ventricle must be of a more direct nature. In a few seconds the auricular waves fell to 250 and the pulse to 43½ per minute.

I waited till this condition of auricular flutter had passed off before I considered that I had an opportunity of trying

FIG. 15.

the effect of amyl nitrite on conductivity. In the upper tracing of Fig. 15 it will be seen that the auricle had resumed its normal action; it was beating at 65; there were escaped beats of the ventricle following on blocking of stimuli, and the a-c interval varied from 1.6 to 2.4 fifths of a second. Inhalation of amyl nitrite at once increased the auricular rate to 91 per minute. Yet in spite of this great demand on the conducting function of the bundle every impulse was transmitted; not only so, but the time of transmission was lessened, as will be seen on comparing the two tracings. The next tracing (Fig. 16) shows that the effect on the conducting function of the bundle began to pass off before the effect on the auricular rate; for

while this remains at 91 we find a progressive lengthening of the α -c interval until this culminates in a block. This tracing also gives evidence that the inhalation of amyl

FIG. 16.

nitrite increases the rate of the idio-ventricular rhythm, for it appears that if the ventricle is left to itself it enters into contraction at the end of a period of about four and a half fifths of a second.

Effect of Atropine.

On another day I tried the effect of atropine on the function of conductivity. However, on taking a preliminary tracing I found that the auricle was again in a condition of flutter. This passed off in about an hour, and the two tracings seen in Fig. 17 were taken. The

FIG. 17.

auricles were beating at 60 and 61, and every fourth or fifth stimulus was blocked. One-fiftieth of a grain of atropine sulphate was then injected subcutaneously; in fifteen minutes all the stimuli from the auricle passed through to the ventricle. This is seen in the upper tracing of Fig. 18. Some impairment of conductivity is indeed

FIG. 18.

still apparent in the lengthened α -c interval, which slightly exceeds the longest intervals in the previous tracing, but in view of the fact that every stimulus is now passing the comparison is not quite a fair one. It will be noted that the auricles are now beating at 54 instead of at 60. This is not the first time I have found atropine produce this effect in the earlier stage of its action, and it might be suggested that the passing off of the block is attributable to a lessened demand on the function of the conducting structures in consequence of this slowing of rhythm. The lower tracing gives the answer to this, because here the auricular rate has gone up to rather more than it was before the injection, and yet, though there is some return of blocking of stimuli, there are long runs where every stimulus reaches the ventricle. Here also, as with amyl nitrite, the effect of the drug is more evanescent in respect of conductivity than in respect of the auricular rate.

SUBSEQUENT HISTORY OF CASE II.

The patient remained in hospital many months, and a great many tracings were taken. A very common rhythm was that shown in Fig. 10, with every second auricular stimulus blocked. At other times the block was clearly a complete one, with a regular ventricular rate of 37 to 40—a rate which is in harmony with the time at which the sporadic escapes of the ventricle have been seen to occur.

About twelve months after her discharge from hospital she was again admitted, having had a sudden attack of left hemiplegia without any loss of consciousness. Both arm and leg were affected, but the weakness was not great; at first there was neither hemianæsthesia nor hemianopsia, but the hemiplegia increased and soon became associated with both these symptoms. In the course of a few days she suddenly became unconscious; very soon Cheyne-Stokes respiration came on, followed by death. During the last days of her life the tracings showed a condition of partial block in which the passing of a stimulus was regularly followed by the blocking of the next, which in turn led to an escape of the ventricle. In this way the radial tracing presented a series of long and short periods, the long ones being rather less than two interauricular spaces, and the short ones being rather more than one interauricular space. Shortly before she died the pulse went up to 85, and though no venous tracing was taken there can be no doubt that, so far as the actual passing of stimuli is concerned, the block had disappeared.

CASE III.

T. M., a labourer, aged 50, was admitted under Dr. Churton, to whom I am indebted for permission to use the case. Alcoholic excess for years; no history of syphilis. Three weeks before admission, at a time when he was not exerting himself at all, he had an attack of loss of consciousness and is said to have been convulsed. He was able to get home by himself. On admission he was found to be the subject of general atheroma; there was great enlargement of the heart; the blood pressure rose during the systole to 210 and the pulse was anærotic. The radial pulse was regular and about 22 per minute. At the apex a systolic bruit was heard which varied very much in distinctness from beat to beat, and which at times was inaudible, the first sound being then loud and thumping. This last sign, pointing as it does to a simultaneous systole of the auricle and ventricle with some of the heart-beats, led to a diagnosis of complete heart-block.

Figure 19 shows tracings of the jugular pulse in the upper and of the apex beat in the lower record, the radial pulse

FIG. 19.

being also shown in each case. It will be seen that though the auricular rate varies from 70 to 77, the ventricular rate is not affected; the block is a complete one. He then began to have long periods of asystole with, after some little time, tonic and clonic convulsions following on loss of consciousness. Of these attacks I saw an immense number; the majority of them conformed to the following description, which I quote from my notes made at the time:

"While lying quietly in his usual condition, the pulse stopped suddenly; he becomes pale, and looks as if he were going to die. I think the respiration becomes less full. Then, after a varying period, usually about fifteen seconds, he becomes unconscious. To test this I was in the habit of getting him repeat numbers or letters after me; he would become confused in his utterance over one or two letters or numbers, and then all response would cease. Following very soon on the loss of consciousness, in about two or three seconds that is to say, begins to have slight tonic spasm, the face being usually turned from the left towards the right, and the head slightly raised from the pillow. Some alteration of expression of the face suggestive of pain is usually noticed. Then, quite suddenly and before the disappearance of the tonic spasm, the patient returns, the first beat as a rule being quite strong and full. At once the face assumes its normal colour, and in a second or two becomes redder than usual. About the same time the tonic spasm, which lasts only a few seconds, passes off, and the patient may again rest on the pillow. Then, almost at once, clonic

spasms of moderate violence come on, and after these have lasted a few seconds, he usually puts his hands to his head, and complains in a confused voice of pain in the head before all the spasm has passed off."

mission, tended to become less frequent, and Fig. 21 was taken at a time when the pulse rate had fallen to 9 per minute. Sometimes long pauses of ten or eleven seconds

FIG. 20.

The tracing shown in Fig. 20 was taken during one of these attacks. The increase in the auricular rate during

FIG. 21. Pulse rate, as calculated from single waves. 9 per minute

FIG. 21.

the period of asystole is well seen, and is doubtless the expression of the fall in arterial pressure. The duration of

occurred, and towards the end of these pallor, without unconsciousness, prevailed.

Apparently in connexion with the long periods of asystole—and here I refer to those which were not associated with convulsion or with loss of consciousness—Cheyne-Stokes respiration was present. The relation was constant and peculiar, and it is shown in Fig. 22; the period of apnoea does not begin until after that of asystole has passed off; there is sometimes an interval of a few seconds between the two phenomena; they never coincide in time. I am not aware that this relationship has been formerly noted. In this tracing the return of the pulse is of the staircase variety. I have looked through my many

FIG. 22.

asystole is twenty-one seconds; the point of time at which consciousness was completely lost is indicated, and it will be seen that the tonic spasm interfered with the record from the venous pulse.

tracings, but find, as I have already mentioned, that as a rule the pulse returns with a full beat.

A Lecture

ON

CAPILLARY PRESSURE AND OEDEMA.*

BY

LEONARD HILL, M.B., F.R.S.

It is generally held, both in physiological and pathological teaching, that the transudation of fluid through the wall of the capillaries is due to the pressure of the blood within these vessels—that is to say, to the force of the heart beat. The average capillary pressure is taken as something between 20 and 30 millimetres of mercury, and it is suggested that this pressure is sufficient to overcome the osmotic force which is found to be exerted through gelatine membranes by the proteins of the blood and separate the water and crystalline substances which pass out from the capillaries into the tissues. According to the modern theory of the secretion of urine, it is assumed that such filtration takes place through the Malpighian capsules, and it is supposed that to maintain this filtration and to overcome the osmotic pressure of the colloids the pressure within the glomerular capillaries is about 20 per cent. less than that in the aorta. The assumption that there is any such high pressure within the capillaries I believe to be erroneous.

My attention was first drawn to capillary pressure some twenty-five years ago when I was inquiring into the principles of the cerebral circulation. I measured the pressure of the brain against the skull wall by means of a tube filled with water and closed by a thin rubber membrane, which was so screwed into a trephine hole that the rubber membrane came into contact with the bulging brain; the tube was connected with a glass tube

containing an air-bubble index, and this by a T-piece with a pressure bottle and a manometer. When the tube was screwed in and the rubber membrane came in contact with the brain, the air-bubble index was pushed out from the zero pressure position. On raising the pressure bottle, so as to restore the air bubble to the zero position, the manometer recorded the pressure required to push in the bulging brain, and restore it to its natural position within the closed skull cavity. The pressure of the brain against the skull wall is due to the distension of the cerebral arterioles and capillaries by the heart, and my method, I believe, gave me a measure of the pressure in these vessels.

In the anaesthetized animal lying in the horizontal position this pressure was about 5-10 mm. Hg, and was the same as the pressure measured in the torcular Herophili; in the dog this was a bony cavity, and therefore suitable for the insertion of a tube and the measurement of the cerebral venous pressure. Trephining the lamina of the atlas and screwing in a tube there, I obtained the pressure of the cerebro-spinal fluid. I found the pressure of the cerebro-spinal fluid, cerebral venous pressure, and the pressure of the brain against the skull wall were the same and varied together, and I concluded that the cerebral capillary pressure is only some 5-10 mm. Hg, and is practically the same as the pressure in the cerebral veins; only the least difference is required to maintain the flow. I may point out here that whether blood is extravasated within the skull or we are dealing with a depressed fracture, either the blood clot or the depressed bone expresses blood out of the brain contiguous to it, and occupies the room of this blood, and so raises the circulatory pressure up to arterial pressure in adjoining parts. The clot or the bone do not continue to press, but occupy room. The increased brain pressure is due to the shutting up of the capillary-sized vessels.

The brain is enclosed within a rigid case—the skull—and the total content cannot vary, but there may be more blood in the brain and less tissue substance and cerebro-spinal fluid on the one hand, while on the other hand

* Given at St. Mary's Hospital in the Institute of Pathology and Research during the course on Pathological Research in its Relation to Medicine.

there may be less blood, and more fluid or tissue substance. The arteries may dilate and the tissue cells may swell, and these together may confine the size of the veins and raise the pressure in the capillaries, so that there is a relatively rapid flow through a more rigid set of vessels, or the arteries and the tissue cells may shrink and the veins dilate, so that there is congestion of these and a sluggish flow. In a healthy state of activity the cerebral arteries are moderately expanded, the tissue cells in a normal state of turgescence, the veins narrow, and the flow of blood and oxygenation good. In a state of collapse the opposite conditions hold: arterial pressure is low, veins congested, or there is more fluid in the spaces, and blood flow is slow and oxygenation poor.

It has commonly been taught that in the eye the aqueous fluid, which is at a pressure of some 25 mm. Hg, is filtered through the walls of the capillaries, the blood within those vessels being supposed to be at a pressure of 20 to 30 mm. Hg higher. That the pressure of the aqueous balances the capillary pressure in the iris is shown by the fact that on letting this fluid escape the iris bulges forward, and may touch the cornea, and on compressing the abdomen the vessels burst, and the blood comes into the anterior chamber. No such bulging or hæmorrhage can be brought about by squeezing the belly when the eye is intact.

Martin Flack and I also showed that when one of the venae cavae was opened, and the venous outflow from it was observed, while the pressure in the eyeball was raised by forcing normal saline into the aqueous chamber, the outflow of venous blood did not cease until the pressure in the carotid artery was just overtopped; this indicated that the capillary and venous pressures rise together and equally with the fluid pressure within the eyeball just as they do within the cerebro-spinal cavity. The contents of the eyeball are confined by unyielding membranes, and the intraocular pressure is ruled by the secretory action of the cells of the ciliary processes. Just as in the case of the brain if the cells secrete more fluid, there is less room for blood, the veins narrow and the capillary venous pressure rises. Suppose the pressure within the blood vessels rises, this increase of pressure is instantly transmitted to and balanced by the aqueous; both in the brain and the eye the pulse helps to keep up the outflow of venous blood and fluid, cerebro-spinal or aqueous.

Abraising the skin, no less than opening the eyeball or skull cavity, removes the balancing counter-pressure of the tissue fluid enclosed by resistant membranes, and allows plasma to escape through the capillaries, which are no longer supported. The tissue cells and capillary walls, too, are damaged by exposure, and the transudation of fluid thus enhanced.

While in the living kidney, confined by its capsule, the pressure of the tissue fluid and secretion balances the capillary pressure; in the dead kidney, on the other hand, water driven through the renal vessels may filter out into the pelvis of the kidney.

A sharp distinction must be drawn between the living conditions and those in a wound or in an organ of a dead animal.

In the case of a salivary gland, it is known that on stimulating the chorda tympani nerve the pressure of the saliva, when its escape is obstructed, rises greatly above that in the carotid artery. Flack and I found that the outflow from the salivary vein was not obstructed under these conditions; in fact the outflow might be rapid, while the gland became tense and swollen. There is a strong membrana propria which confines the secretory cells of each alveolus and limits its expansion, acting like the leather case of a football or the pericardium of the heart. Each lobule and lobe and the whole gland is surrounded with membranes limiting expansion. When the secretion is obstructed the alveoli swell, the lobules and lobes swell, and the whole gland swells until limited by the membranes, and the veins within the gland are narrowed while the arteries dilate owing to the influence of the vasodilator nerves, and the circulatory pressure is thus raised until arterioles, capillaries and veins approximate towards a rigid system at arterial pressure with a fast rate of flow.

In the sweat glands the structure is similar; the same high secretory pressure can be produced. In the kidney there are figured membranae propriae enclosing secretory cells of both renal capsules and tubules, but they are less well defined. The secretory pressure does not rise up to the arterial pressure.

Direct Measurement of Capillary Pressure.

Now let us turn to direct measurement of capillary pressure. Roy and Graham Brown used a small brass cylinder closed at one end by glass and at the other by a cup-shaped piece of transparent peritoneal membrane. A tube entered this little chamber, by means of which the pressure could be raised within it, a manometer being attached to indicate the pressure. With the peritoneal membrane in the domed-up position, the web of a frog's foot or other transparent tissues can be brought in contact so as to flatten down the dome somewhat. The web is then covered by a thick glass cover-slip attached to a holder. The chamber is placed beneath the low power objective of a microscope, and the capillary circulation observed. The pressure is then raised in the chamber so that the web is compressed between the membrane and the glass cover-slip, and the pressure is found which just obstructs the flow. In the case of man a similar apparatus inverted has been applied to the skin just behind the finger nail, and strong direct illumination used. A drop of castor oil is placed upon the finger before the application of the membrane; and the capillaries can then be seen in the papillae of the skin. Measurements of this kind have been made by a considerable number of observers, and give high values such as 20 to 40 mm. Hg.

Instead of microscopically observing the capillaries of man in the way just described, another method has been used—namely, that of finding out the pressure which just suffices to blanch a small area of the skin, as seen by the naked eye. To blanch the skin, 55 to 75 mm. Hg are required according to some observers, but the average generally given is 35 to 45 mm. Hg.

Basler has compared the colour of the compressed finger with another placed beside it, and taking the least change of colour as the index has found a much lower pressure than other observers—namely, 5 to 8 mm. Hg. He has also used a very ingenious method of making a small cut in the finger and inserting the finger in a tube connected with a manometer and finding out the pressure the escape of blood raised the manometer. Again he finds the same low pressure. Now it is clear that in cutting the finger one probably would not only cut capillaries but might wound an arteriole, and the pressure might, therefore, indicate not capillary pressure but that of the arteriole.

The arterioles in their end branches consist of endothelial cells and circularly arranged muscle cells. As they branch into capillaries the muscle cells cease, and the capillaries have an endothelial lining only. When the capillaries join together to form the venules, the endothelial lining first becomes coated with connective tissue fibrils, and then further on muscle cells are added. It seems very unlikely that there should be any difference of pressure between the venous end and the arterial end of the capillaries. We know that the pressure is very small—for example, in a number of observations made by Bayliss and Starling on dogs while the pressure in the aorta was 81 to 125 mm. Hg, that in the vena cava was from 2 to 5 mm. Hg, the pressure in the portal vein 5 to 8 mm. Hg. If in the upper arm the pressure is measured which just stops the outflow from the lower, the arm being placed horizontally at heart level, it is found to be from 1 to 5 mm. Hg (L. Franks, Elpers).

The method used by Roy and Brown, and the method of blanching the skin first used by v. Kries, are methods which stop the flow of blood in the capillaries or arterioles, but obviously, if the flow of blood is stopped, the pressure rises to that within the arteries which feed these vessels. What has been measured then has been capillary pressure but the pressure in the arteries.

Krogh, who has made a great many observations of interest recently on the contractility of capillaries, has found that mechanical excitation causes a contracted and a dilated capillary in the frog's tongue to dilate at the venous end first and the blood to advance from the venous end until finally the capillary dilates up to its connexion with the arteriole, when the current is suddenly reversed. He finds then that the venous pressure is enough to fill the capillary, and overcome the resistance to flow within it, and the venous pressure is agreed to be only a very few millimetres of mercury.

I have examined the capillary pressure, using a

form of the Roy and Brown apparatus, kindly made for me by Dr. E. Schuster—

1. In the tadpole's tail.
2. In the toad's lung, tongue, mesentery, and bladder.
3. In the frog's lung, tongue, mesentery, web, bladder, and kidney.
4. In the newt's lung and mesentery.
5. In the grass snake's lung, mesentery, and kidney.
6. In the mouse's ear, mesentery, and abdominal muscular wall.
7. In the cat's mesentery and muscle.

To determine the pressure correctly the transparent membrane covering the compression chamber must be tied on loosely, as Roy and Brown direct, so that when blown up it forms a dome over which the web or other organ is spread; the threads attached to the toes in the case of the web, for example, are carried to pins, and the leg arranged so that the flow of blood is free and unobstructed. The glass against which the web is compressed is lowered until it touches the web, the top of the dome being thereby slightly flattened. The web is compressed between the flattened part of the membrane and the glass. Care must be taken to secure that the toes are not pressed by the glass cover against the metal rim of the pressure chamber, and that pressure is not spent in merely expanding the membrane.

Capillary pressure I take to be that pressure which just begins to lessen the velocity of flow in those capillaries wherein the flow is slowest. These naturally first undergo compression, the blood taking the pathway of least resistance through other capillaries. If the compression be gradually increased the flow is slowed, then stopped in more and more of the capillaries until it continues only through the most direct pathways connecting the arterioles with the venules wherein the velocity was greatest to start with. With further increased compression the flow of blood becomes pulsatile not only in the arterioles but in these capillaries and even in the venules, the compression being sufficient to stop the flow in diastole, but not in systole. Finally the blood is expressed out of the capillaries and veins, and the pulse is seen swinging the corpuscles to and fro in the arterioles, but not translating them onwards. The pressure required just to produce this effect is the systolic pressure in the arterioles supplying the compressed part.

All those phenomena which take place on the application of pressure to the arm by means of the cuff of the sphygmomanometer can thus be observed and taught to the student. The diastolic pressure can be measured in the frog's web just as well as the systolic pressure. Diastolic pressure is that which just arrests the onward flow of the corpuscles in diastole; to give an example, in a frog's web diastolic pressure was 17 mm. Hg and systolic pressure 26 mm. Hg.

The pressure required just to modify the capillary flow in the outer part of the tadpole's tail or at the edge of a frog's web is from 1 to 3 mm. Hg. There are some capillaries which require a higher pressure than this—for example, 5 to 8 mm. Hg—such as the capillaries in the papillae of the frog's tongue, or in the glomeruli of the kidney of the frog. Glomeruli may be observed with the blood corpuscles running through the afferent vessel, spinning round the network of capillaries and out by the efferent vessel—the whole giving a most striking picture. The following is the technique which was briefly described in the *BRITISH MEDICAL JOURNAL* of April 9th, 1921, p. 526:

The frog is put under urethane, an injection under the skin of the back of about 0.3 c.cm. of a 20 per cent. solution being given. The animal chosen is a rather small active one, not a female full of spawn. It is fixed on its side by pins through hip and ankle-joints; a lumbar incision is made through the skin and abdominal wall and the ileum on that side is removed. All haemorrhage is stopped by means of a cautery heated to a dull heat. The external edge of the kidney on which runs the renal portal vein is picked up in the forceps about the middle of the kidney and a ligature tied on at this point. The animal is then arranged belly upwards at the side of the Roy and Brown apparatus, and by a very gentle traction on the thread the kidney is drawn over the peritoneal membrane and the glass cover brought down upon it. The manipulation of the body and the traction on the thread must be so carried out as to expose the outer edge of the kidney to the light, when brought under the microscope, without stopping the circulation in the renal arteries. It is along this edge that the glomeruli may be found.

On examining the preparation the whole surface of the kidney is seen pervaded with wide venules and their capillary branches coming from the renal portal vein, through which the blood is flowing in slow and most ample streams. On putting on a pressure of 2 to 3 mm. Hg the blood is squeezed out of these veins, and glomeruli may then come clearly into view and exhibit the arterial blood coursing through them. I found a pressure of some 4 to 8 mm. Hg definitely slowed the flow in the glomeruli, while it took some 25 mm. Hg to stop the flow in the renal arteries. There is nothing extraordinary about the behaviour of the glomerular capillary network; it resembles that of other capillaries; the flow in the afferent and efferent vessels is stopped by the same pressure. I found it took very little pressure to drive the corpuscles out of the glomerulus when the circulation had stopped. I have seen the flow reverse under pressure before the glomeruli empty.

I find that a pressure of 2 to 5 mm. Hg momentarily applied checks the flow of corpuscles in the arterioles of the frog's web, etc., while it takes some 25 mm. Hg to stop the flow altogether. In the chief capillary branches, where the velocity of flow is rapid, the same pressure momentarily checks the flow, and at the same time as in the arteriole, but in the case of the venules the flow may be accelerated during and retarded momentarily after such an application of compression. The acceleration is due to the expression of blood from the capillaries, the retardation to the capillaries filling again. The pressure which momentarily checks the flow in the arteriole is, I take it, a measure of the pressure of the blood against the wall of the vessels. It closely approximates to that pressure which, when continuously applied, retards the flow in those capillaries with the slowest rate of flow. If the compression is maintained the pressure, of course, banks up behind it to that of the artery which feeds the obstructed arteriole. As the water manometer, owing to its inertia, does not fully record the value of the momentary compression, I have also used an air manometer with a xylol index, graduating this against the water manometer.

The conclusion then is reached that the pressure in the arteriole with unobstructed rapid flow is 2 to 5 mm. Hg, and that the fall of pressure from arteriole to venule is a very slight one. The flow in the venules is affected by a pressure of 1-2 mm. Hg.

The observations I have made on the mouse and cat show that the pressure in the capillaries and arterioles is no higher in the warm than in the cold-blooded animal. The assumption which has been made that the capillary pressure is some 30 mm. Hg, and the hypotheses as to the transudation of lymph, urine, etc., based on that assumption, appear then to be untenable.

Proof that the resistance in the capillaries is very slight is afforded by the following experiments: If the flow in the frog's web or tongue is stopped by a ligature placed round the thigh, we find, on exploring the field, one or more of the vessels, an arteriole, say, connecting some capillary with a venule, in which the flow continues for some minutes at a speed which is scarcely less than the normal speed in the capillaries. I have seen such a flow in the capillaries of the frog's web on placing it under the microscope forty minutes after cutting off the leg. The application of warm water to the web may restart such a flow when arrested. The flow may reverse, and this is against its being caused by contraction of the arteries. Again, when the web of the excised leg is compressed in the Roy and Brown apparatus a momentary pressure of 2 mm. Hg will cause the corpuscles to rush along the capillaries and venules no less rapidly than in the normal flow.

To try and arrive at a juster measure of the pressure in the capillaries in man my co-worker, Dr. James McQueen, designed the following method:

Warm water from a jet fed from a reservoir kept at constant pressure-head is played on the skin below the nail or on the skin covering the distal end of the metacarpal bone of the thumb, the jet having a 2 to 2.5 mm. bore diameter. If the pressure be sufficiently high, the area impinged on is rendered white, and when the jet is moved a red blush of returning blood can be seen. To determine the pressure which just suffices to produce blanching, the jet is now turned so as to throw its column of fluid into the air alongside a meter scale; the distance of the upward throw of water is obviously the pressure of impact on the thumb in centimetres of water.

When readings of pressure are taken by this method with the arm held at heart level they do not materially

differ from the readings of pressure obtained by v. Kries and others. But, be it noted, as the flow is stopped in the blanched part the readings are of arteriole not capillary pressure. Moreover, there remains to be considered the considerable resistance of the convex horny layer of skin to compression. There are also the resistance of the vascular wall to compression, the friction of the blood as it is expelled from the compressed area, the resistance of the lymph or tissue fluid surrounding the capillaries. These resistances are very small, as is shown by the fact that a pressure of 1 cm. of water applied to the membrane of the Roy and Graham Brown apparatus is sufficient to drive the corpuscles quickly along the vessels of the web wherein the circulation has been arrested. Their sum can be accurately estimated provided the blood pressure in the compressed area can be reduced to zero. Then the pressure taken to blanch the area is a measure of the resistance factors. To effect this the hand is raised above the heart level, at a certain point the veins collapse, because the venous pressure has been overtopped by gravity, and is, in the hand, zero. If the brachial artery is now occluded, the arterial pressure entering the hand is, in its turn, reduced to zero. Accordingly the capillary pressure becomes zero. A tourniquet of rubber tubing can be used, or the cuff of the sphygmomanometer connected with a compressed air cylinder so as to secure a rapid application of pressure to the artery.

In order to keep enough blood in the capillaries to give a clear index, it is advisable to put a rubber band round the wrist before elevating the arm and compressing the artery, and then to remove this band. If the jet be projected on the thumb when the area has thus been brought to zero pressure, a measure of the pressure in centimetres of water required to blanch the area is now obtained. This pressure measurement—the measurement of resistance factors—has to be subtracted from the original measurement obtained when the normal conditions of pressure pertained in the arterioles. The diminished reading is now the actual arteriole pressure. To cite an example:

Subject E.—Hand at heart level. Pressure to blanch 2.5 mm. area=35 cm. water. Resistance measurement (after vascular area reduced to zero pressure)=24 cm. water. Difference=arteriole pressure=11 cm. water. This method gave us an arteriole pressure of about 10 mm. Hg.

In the case of the bat's wing I found the main arterial branch in the second segment measured about 0.08 mm. in diameter, and the main arterioles about 0.015 mm., these coming off at right angles. When the bats are hibernating the pressure in the main branch is low, rising from some 20 mm. Hg to 50 mm. Hg as the bat becomes warm. When the systolic pressure in the main arterial branch is 50 mm. Hg that in the main arterioles is about 15 to 20 mm. Hg.

There is then a great drop of pressure on passing from the main arterial branch to the main arterioles. It is in these vessels that the great fall of arterial pressure takes place through resistance to rapid flow.

I now pass to the consideration of the contractility of the capillaries.

Effects of Arterial Contractility.

According to the general view the contractility of the arteries regulated by vasomotor nerves controls the flow of blood to each part, diverting greater streams to parts in action. But the contractility of the capillaries and venules is now an established fact, and the evidence seems to show that it has an important share in the local and general control of blood flow. Stricker (1865) noted on appropriate stimulation the constriction of the capillaries in the nictitating membrane of the frog, and ascribed it to turgescence of the endothelial cells, which form the capillaries. His observations have been confirmed by several, but no one has proved how the constriction is brought about.

The capillaries of the web dilate after the momentary touch of a brush dipped in chloroform, stasis being prevented by well washing with water. Inhibition of the heart had no effect on this dilatation, it was not brought about by blood pressure (Roy and Brown). A small drop of nicotine applied locally to the area vasculosa of the chick on the fourth day of incubation produced such dilatation that the rest of the area was almost emptied (Vulpia). Lewis and his co-workers found that in the arm, with the artery blocked by the cuff of the sphygmo-

manometer, a scratch on the skin with a blunt instrument produced the well-known white and red lines. In such case they must be ascribed to capillary contraction and dilatation. Local injection of adrenin also blanched the skin when the arterial flow had been stopped.

Temporary anaemia produced by ligation or compression of an artery dilates the capillaries. Almroth Wright attributes this to the production of acid through anaemia. We know that oxygen want leads to the appearance of lactic acid in muscles, and a drop of acid dilates the capillaries. On the other hand, Krogh attributes the dilatation to some unknown property of the blood, for he finds it takes place when the frog's tongue is exposed to oxygen. The capillaries are conceived by him as spontaneously contracting and dilating, and thus alternating the blood supply to the tissues, dilatation following on the anaemia produced by contraction.

Krogh finds that local mechanical, or thermal, stimulation, or the application of minute drops of weak acid, cocaine, and adrenaline produce local dilatation of both arterioles and capillaries. The effect spreads to a wider area than that stimulated. A drop of urethane (20 per cent.) dilates the capillaries and not the arterioles. The spread of the reaction due to stimulation is abolished by cocaine, and not affected by mere section of the nerves, but disappears when the nerves have degenerated, being then sharply limited to the point excited. The reactions are considered to be due to a spread of excitation along sensory nerve fibres to that antidromic vaso-dilator effect discovered by Bayliss in the posterior root axons. The contraction of capillaries may reduce their diameter by more than half and their sectional area fivefold. Dilatation occupies several seconds, contraction one to three seconds. A single stimulus is ineffectual; the galvanic current is better, and mechanical stimulus most effectual. A vast number of capillaries are at any one time not open, as may be seen by the growing flush and swelling of the hand on occluding the veins of the arm. The aching sensation which arises from congestion keeps one naturally restless, and every movement helps onward the flow.

Krogh finds an enormous increase in the number of open capillaries in muscle during activity. In the mammal he used intravenous injections of Indian ink to render the capillaries visible. He estimated that in the guinea-pig the total surface area of the capillaries per cubic centimetre of muscle was 3 to 32 sq. cm. at rest and 360 to 750 in activity; in the frog 1 to 12 sq. cm. at rest and 70 when active. The oxygen supply to the active muscle is thus kept ample.

I find a very instructive preparation of the abdominal muscular wall of the mouse (under urethane) can be made by an incision through the median line of the lower half of the abdomen and another carried laterally outward from the mid-point, the skin being reflected, the triangular flap of muscles with the blood vessels entering from it is brought on to the membrane of the Roy and Brown apparatus. In such preparations all the capillaries appear filled, perhaps owing to exposure or to the fact that the muscle is always in respiratory action.

Venous Contractility.

In the hibernating bat's wing most of the capillaries empty, and the veins contract in such period as to help the feeble flow. There may be, and probably are, contractions of all veins which further flow. We know that muscular contractions and change of posture greatly contribute to the return of the venous blood to the heart. Thus Burton and Cope on stimulation of the sciatic nerve found the outflow from the femoral increased three to four times above the resting value during the shortening of the muscles, but it was diminished to about a third during the height of tetanus.

Hooker isolated the sigmoidal area of the large gut of the dog, and leaving the artery open connected the vein with a manometer. Excitation of the nerve supply from the inferior mesenteric ganglia increased the venous pressure by 5 mm. Hg, asphyxia increased it by 31 mm. Although the lumen of the gut did not show this rise in pressure when closed and connected to a manometer, Hooker believes that the contraction of the tissues caused the rise.

Hooker also finds that after death from ether capillaries first contract and empty, then dilate and fill, and finally contract and empty when rigor comes. This does not happen in the cat in a state of shock, for example, in one poisoned by histamine.

The arteries of the ear in such a cat contract on stimulation of the nerves or on injecting adrenin, but not the dilated veins and capillaries.

Shock.

The work of Dale and his co-workers indicates that shock produced by histamine has its origin in primary failure of the peripheral circulation. All the capillaries open and venules dilate at once, and there is increased passage of fluid from the blood into the tissues, and so the circulation fails while the heart is beating efficiently. While Dale injected histamine, I watched the venules dilate in the mesentery and the flow slow down and almost become arrested in these and in the capillaries, but have not so far been able to see the opening up of closed capillaries, probably because the capillaries are already dilated by exposure. Histamine is formed by decarboxylation of the amino-acid histidine, which is derived from proteins, and it is conceivable that such substances are produced in trauma. Herein we have an explanation of shock differing from that of acid causation put forward by Almoth Wright.

Be it noted, histamine acts in the cat anaesthetized by ether, but not in the normal cat or one anaesthetized by nitrous oxide and oxygen. The last is by far the best anaesthetic for preventing shock, and as P. Bert proved forty years ago, and Dale and I have confirmed recently, may be given with ease and safety and efficiency of depth in a pressure chamber at +7 lb. pressure. An operating chamber can easily be constructed so that the patient, surgeon, and anaesthetist are all within the chamber at slightly increased atmospheric pressure. The effect of inhaling gas and oxygen, given in the usual way from a bag in such a chamber, is an increase of partial pressure, or concentration, of both in the blood, and deep anaesthesia with no want of oxygen.

Effects of Oxygen Inhalation.

The beneficial action of oxygen inhalation in relieving oedema and chronic ulcers has recently been made evident to me by the use of an oxygen tent bed, constructed for me by Messrs. Siebe, Gorman, Ltd. This tent bed allows 30 to 40 per cent. oxygen to be breathed in comfort for days, with intermissions for meals. The oedema disappears, the part becomes warm and of good colour, the granulations healthy, the edges of the ulcer flatten, and the skin hastens to spread over the ulcer.

The question arises as to how the capillaries contract and dilate. It is generally assumed, but unproven, that it is due to changes in the swelling of the endothelial cells of the capillary wall. I suggest that it is due to the tissue cells outside the capillaries; these, by swelling or shrinking, control their own blood supply. By increase of waste products with higher osmotic pressure they take up fluid from the blood in the capillaries and swell, and so contract the capillaries. By chemical-physical changes resulting from the taking up of fluid from the blood the osmotic pressure falls, and the fluid passes back into the blood or lymphatic channels.

I have pointed out what happens in the salivary gland on excitation of the chorda tympani, and how the membranes propriae and other membranes confine tissue expansion so that the capillaries and veins may be narrowed but not occluded. I do not believe fluid is transuded out by the force of the heart producing a filtering pressure, but that the heart just succeeds in maintaining a flow in the capillaries with no excess of pressure for other purposes, and the tissues by inhibition swell or shrink, taking or giving up fluid.

Charles Bolton, narrowing the inferior vena cava to one-third by a rubber ring, has shown that oedema results in dogs, not when the temporary small rise of venous pressure occurs at first, but later, when the venous pressure has returned to normal. Oedema is due to ill nutrition of the tissues, not to increased vascular pressure and filtration, whether it arise from poor flow and want of oxygen in heart disease or from a chemical poison in kidney disease, or from a bacterial toxin.

The swelling of the tissues in oedema, by pressing upon the venules, raises the capillary pressure.

I have measured the pressure in a case of hydrocephalus with the infant lying horizontal. It was nearly 15 mm. Hg. On raising the head from the pillow the pressure

rose owing to my hands squeezing the head which was a bag of fluid. The capillary venous pressure in the pial vessels must have risen *pari passu*, there is no mechanism for shielding them from the pressure of the fluid. I moreover found, on drawing off the fluid, that the pressure sank to 0—that is, to atmospheric pressure—and the soft wall of the skull by its weight sagged in. So it remained for hours, until the fluid was re secreted.

In a case of oedema of the leg, with the patient sitting propped up, the pressure of the fluid equalled about 40 mm. Hg; here again the pressure rose on lifting the leg up, owing to squeezing by the hands, and the capillary venous pressure must have risen *pari passu*, and kept as it is normally, the least bit above the tissue fluid pressure, so as to maintain the venous outflow.

In inflammation the products of tissues damaged by bacterial toxins cause dilatation of arteries and swelling of tissues. The swollen tissues, confined by the membranes, press upon and narrow the veins and capillaries. The blood pressure rises, and we have a more rigid system with fast flow, redness, swelling, and a throbbing pulse in the part. The tissues may swell so that stasis is produced; the surgeon's knife then relieves the swollen, tense condition, and allows lymph with its immunizing powers to escape. Bier's bandages obstructing venous flow may cause increased outflow of lymph, not by transudation under pressure, for capillary pressure is balanced by tissue fluid pressure, but by increased imbibition of tissue cells due to oxygen want. The salt solution treatment of wounds devised by Almoth Wright pulls fluid out in increased amount, and washes the wounds just as the breathing of cool air, with its low water vapour content, by evaporating moisture from the respiratory membrane, draws abundant lymph from the blood and keeps this clean and healthy.

Krogh finds that, after putting in a drop of 20 per cent. urethane on the capillary field and injecting neutral red intravenously, the dye passes through the dilated capillaries and stains the bordering tissue, the stain fading away from the capillary. This he ascribes to increased permeability. It may equally well be due to increased force of inhibition exerted by the damaged tissue cells. The escape of white blood cells during stasis and of red cells on severe injury shows a pathological permeation of the capillary wall; but normally the tissue cell, not the capillary pressure, governs the passage of fluid.

DUAL RADIOTHERAPY IN MALIGNANT DISEASE.

BY

S. GILBERT SCOTT, M.R.C.S., L.R.C.P.,

DIRECTOR OF THE RADIOLOGICAL DEPARTMENT, LONDON HOSPITAL.

X RAYS and radium are undoubtedly powerful therapeutic agents. But, since the technique required to obtain their complete beneficial results has not as yet been mastered, we are at present unable to make full use of them. Consequently most of our failures must be attributed to the uncertainty of our technique rather than to the agents themselves.

Physicists have given us much help in solving some of the problems connected with x rays and radium. But until they can give us not only an accurate means of measuring dosage to pathological cells lying below the surface of the skin, but also indications of the conditions and dose required to produce a full lethal effect on these cells, our results are bound to be erratic. At present results depend partly on luck—that is to say, on whether the particular dose administered happens to be the most effective one—and partly on the practical experience of the radiologist, which enables him to gauge this with a certain amount of accuracy. It should, indeed, be possible to administer x rays and radium radiations as accurately as drugs. It should equally be possible to have some idea of the prescription required for the case in hand.

There are, perhaps, no therapeutic agents affecting such a variety of diseases, or from which more remarkable

results can be obtained in many cases otherwise hopeless. The work carried out by the x-ray treatment department of the London Hospital in the course of the last ten years bears out this statement. Over 11,000 new cases have been treated, averaging 5,000 attendances a year. This total includes 115 different diseases, ranging from deep-seated and malignant tumours to conditions so superficial as warts and corns. It is clear that control of dosage is essential in the treatment of such widely separated diseases.

Out of the total given above, 1,500 were cases of mammary carcinoma, some requiring prophylactic treatment, others being recurrent or inoperable. Carcinoma of the breast being the largest class of cancer cases, I endeavoured to find out and classify the results of x-ray treatment in the hope of improving our methods. The tracing of hospital patients was impracticable. Statistics are apt to be deceptive. But in the case of patients who were traced, metastases in the thorax accounted for a large percentage of deaths, although the superficial recurrences had been controlled. Was it not possible to control these deep metastases in the same way as the superficial? Clearly, any successful method must fulfil two conditions: (1) It should be possible to administer a dose lethal to pathological cells lying at various depths and in unknown positions; (2) the radiated area should be large. The importance of the second factor is emphasized in a valuable paper on the "The Spread of Breast Cancer," by W. Sampson Handley, in the *Archives of Radiology and Electrotherapy* (October, 1920).

In the hope of fulfilling these two conditions, I devised the dual method of radiotherapy which has been installed in temporary quarters at the London Hospital. Although designed for the treatment of carcinoma of the breast and thoracic tumours, it can be used for many deep-seated conditions, such as abdominal tumours, splenic cases, and it may, I believe, prove of some value in the treatment of pulmonary tuberculosis.

Rationale of Treatment.

The complex question of dosage cannot be discussed here, but I have for some years based my deep therapy on the following principles: (1) Full cell absorption; (2) production of a large number of heterogeneous rays; (3) a filter only thick enough to protect the skin and to cut out rays of little or no therapeutic value. These were suggested by facts supplied by physicists and by gleanings from my personal experience. Although I cannot here go into further details, the results in the more superficial conditions have been up to the present so satisfactory that an elaboration on the same lines, such as with the dual method, seemed justified. Any new scheme for deep therapy should be founded on a logical basis. It must be admitted that our knowledge of the actual influence of x rays on the living cells is meagre; but I think it is sufficient to indicate the lines that should be followed, even though these may have to be altered as our knowledge increases. I do not think the full therapeutic value will be obtained by endeavouring to produce x rays with the penetration of radium at the expense of maximum cell absorption. I suggest that there is some unknown factor in radium radiations which, apart from their high degree of penetration, may account for their therapeutic effect. The reports of the Radium Institute show that the therapeutic results of radium radiations are equal to those of x rays properly administered, their chief value being in cases where the disease is inaccessible to the latter, whilst their disadvantage lies in the limited field of radiation.

Technique.

The shortcomings of our present methods are these:

1. The dose administered to the deep-seated and scattered pathological cells is too small.
2. The area treated is much too limited.

The dual method for deep therapy, of which I have found no mention in the literature, consists of two separate installations, of which one operates a tube in front, the other a tube at the back of the patient, who is in the sitting position, both tubes running simultaneously. After the first full dose has been administered the direction is changed, so that the radiation is now from side to side, the arms being forward and raised. In this way the

deepest parts of the body are subjected to radiations from the four points of the compass, and the resulting cell absorption must be very much greater than with our present methods, although the more superficial, or skin dose, controlling superficial recurrences, remains the same.

By this method, which may be described as a combined cross-fire, the deficiencies of current methods, referred to above, are avoided; that is to say, (1) by working both tubes at the same time from both sides of the body a larger dose is administered to the deeper pathological cells; (2) a very large area is covered.

It is doubtful whether any additional therapeutic effect is to be expected from the coincidence of the rays in the deeper tissues. At any rate, malignant cells in the tissues, lymph channels or blood stream, must certainly come under the influence of the radiations.

The radiation of a large area did not present much difficulty. It merely entailed the manufacture of a protective shield or tube-box with a large opening. I preferred a lead glass shield, but as I was unable to obtain one with an opening large enough for my purpose, I utilized the standard one reversed—that is to say, the smaller opening, blocked by protective material, not only holds the shield in position, but admits the air-blast, directing it to the back of the tube. The larger aperture now faces the patient, giving a very large radiation field, including, at a reasonable distance, practically the whole trunk, axillae and supraclavicular fossae.

I consider it important that the maximum dose the patient can tolerate should be administered at the first and at every subsequent sitting. If this is not done, there is a possibility of the pathological cells being encouraged or stimulated to assume defensive measures against the destructive effect of the radiations. We all know that some kind of acquired immunity, not to be confused with stimulation, may occur. Cases that respond well at first may quite suddenly cease to do so if the treatment is prolonged and the dosage too light.

To put it briefly therefore: "Always hit hard; do not continue treatment once you have achieved your object."

Blood counts are at present carried out in all patients immediately before and after exposure, and at varying intervals subsequently, with a view to ascertaining the maximum dose they can tolerate. But, when once this is established, these frequent blood counts will probably be unnecessary—at any rate in cases of mammary carcinoma. In all cases of cancer the thorax is carefully examined radiologically before treatment, and a plate taken as a record.

We cannot as yet decide definitely how frequent the treatment should be; this must, to a certain extent, depend on the blood changes and other symptoms, the significance of which is still debatable. At first, patients were treated once a week, receiving 20 X skin dose through 3 mm. of aluminium at each of the four areas—the front, back and two sides, giving a total of 80 X at each sitting. Six of these would have completed the first series of 480 X, but it was found that only a few patients could tolerate the full 80 X dose. The occurrence of nausea and vomiting within a few hours of treatment (sometimes lasting as long as three days) demonstrates, I think, the fact that tolerance to x rays has been reached and is limited in different patients. I believe, however, that by working up to the maximum gradually, secondary symptoms may be avoided. These after-effects may not necessarily be the results of x rays; ozone and nitrous fumes may cause the sickness. The whole matter is being investigated.

Treatment is now administered weekly: anteriorly and posteriorly the first week, the second week from both sides, the total dose being 40 X through 3 mm. of aluminium in each week. Although many tolerate it, there are some who cannot stand even this dose.

DOSAGE.

Registration of Dosage.

Accurate measurement of the dose absorbed by the pathological cells composing even a single tumour is practically impossible. At present only a very rough calculation can be made, and even this is dependent on several unknown factors. The difficulty is still greater when we are endeavouring to irradiate a number of cells scattered about in the body at unknown depths and in unknown positions. The best we can do is to measure the maximum

skin dose under certain known conditions and give as large a dose of heterogeneous rays as possible. The calculation of the skin dose used in the treatment of tinea is simple and accurate, but difficulties arise when a filter is inserted. We have the Sabouraud pastille, the Kienböck strip, the Holzknecht strip, and many others by which the dose can be gauged, but most of these are intended for use without a filter. We are waiting for a simple practical unit for filtered rays.

For want of a better I have, for many years, used the Sabouraud pastille on the skin as my unit, Kienböck's strip not being very practical, as an overdose or underdose may easily be given, usually too late to remedy the error. The time factor with a Coolidge tube is fairly accurate, but even here each tube must be tested periodically by some method or other. It is better to take the reading on the skin itself, as the distance of the tube and the thickness of the filter can then be practically disregarded, although this process involves the establishment of a new unit. The main difficulty when using a Sabouraud pastille on the skin is the reading of the slight tint alteration that takes place, but this may be overcome by the use of a tintometer.

I have found from experience that the effect on the skin of an erythema dose through a filter was not the same as without a filter, a fact which, I believe, agrees with the expectations of physicists. Realizing this, would it be possible to fix a unit which would give us the danger dose through a filter? The method I adopted some years ago to gauge roughly the maximum skin dose with a filter, when treating deep-seated tumours, is as follows: A Sabouraud pastille is placed on the skin; when this registers a quarter B tint the skin has received a 10 X dose, irrespective of the distance of the tube or of the thickness of the filter. This was taken as the minimum dose, not as the erythema dose, the maximum which I have applied being a 20 X dose, again measured on the skin through 3 mm. of aluminium. The pastille in this case will read $\frac{1}{2}$ B tint. The $\frac{1}{2}$ B tint and the $\frac{1}{4}$ B dose must not be confused; they are entirely different. Penetration should not be below 9.5 Welnet. Caution is required by the operator in using these large doses; they should be worked up to gradually. The margin of error being small, a certain amount of proficiency in the use of the apparatus and in the reading of the pastille changes is essential.

I have given this 20 X dose through 3 mm. of aluminium as often as twice a week in desperate cases with no resulting skin changes beyond deep pigmentation. Such possibilities as late reactions must be risked when the patient's life is at stake.

Possible Dangers.

1. *Blood*.—Massive doses are said to lead to definite blood changes, the details of which cannot be gone into here. With the dual radiotherapy, not only is the total dose large owing to the extensive area of the body subjected to radiations, but the heart, when thoracic conditions are being treated, is being radiated from all sides. I believe, however, that any blood changes that occur are caused by the direct action of the rays on the blood-making tissues, such as the spleen and bone marrow, rather than on the blood corpuscles. So far no blood changes have been found.

2. *Intestines*.—Various organs are said to be influenced by radiations, amongst them the intestines. As the dual method has not yet been applied to abdominal cases this point cannot be settled. A careful watch should be kept on all patients under treatment for indications of possible damage to organs in the field of radiation. Any undesirable effect should be rectified by modification of dosage and frequency of treatment.

Results

The first patient was treated by the dual method only on February 24th, 1921, and some time must therefore elapse before any reliable data can be expected where an effort is being made to prevent metastases, but in those cases in which the primary lesion has been treated, such as an intrathoracic growth they appear to respond very much more rapidly than with the localized method used previously.

It must always be remembered that the time is possibly approaching when the cure may prove worse than the

disease. In our efforts to destroy malignant cells we may destroy far more than we intended.

The *secondary phenomena* so far noted are of some interest. Few can tolerate the full 80 X dose, nausea and vomiting, lasting from several hours to three days, appearing shortly after treatment. If, however, the dose is halved—two opposite areas only being treated instead of four—the patients may experience a feeling of well-being, which one patient aptly compared to the effect of a glass of champagne. In one case, that of a large intrathoracic growth (the patient was a doctor), the secondary symptoms—nausea and vomiting—were very marked after even the first 40 X dose, yet others experienced no ill effects whatever, even after the full 80 X dose. These secondary phenomena are somewhat puzzling and are being investigated, as other causes besides the direct action of x rays may be responsible.

I have given but a rough description of the method, hoping that others may work on the same lines, and that at some future time interesting comparisons and conclusions may be made.

Radiologists appear to have divided themselves into two schools—those who endeavour to attain maximum cell absorption and those who pin their faith on excessive penetration at the expense of absorption. The dual method follows the cell absorption line of technique.

FURTHER REPORT ON THE TREATMENT OF SLEEPING SICKNESS.

By

CLAUDE H. MARSHALL,

SENIOR MEDICAL OFFICER, UGANDA PROTECTORATE
AND

S. M. VASSALLO,

MEDICAL OFFICER, UGANDA PROTECTORATE.

In a previous report published in the *BRITISH MEDICAL JOURNAL* of May 22nd, 1920, p. 702, by one of us (C. H. M.), attention was drawn to the treatment of sleeping sickness by combined intravenous and intrathecal injections of organic arsenical preparations (neo kharsivan). An epitome of twelve cases thus treated was also given.

Since then the number of cases treated and under observation has increased to over 50, and the conclusions we have drawn are that this treatment shows prospects of a possible cure for, at any rate, early cases of this protean disease.

The following is a summary of the technique of the treatment, given in detail in the report previously alluded to:

An intravenous injection of an organic compound of arsenic is given, and after a period varying from one to four hours a certain quantity of blood—usually 20 c.cm.—is withdrawn. This is kept in a vessel, stood in cold water, until the serum separates completely from the formed elements of the blood. The separated serum is then injected into the cerebro-spinal cavity, an equal amount of cerebro-spinal fluid having been previously drawn off. This completes the treatment, and the patient is free to resume his normal life, subject to his reporting from time to time for re-examinations.

The principle of the treatment was based on the theory that the trypanosomes having once reached the cerebro-spinal canal were, after a certain time, immune to any medication via the blood stream; since we have adopted this routine procedure for sleeping sickness cases we have had striking examples of this fact.

The following are examples:

Case 30

Karungabo, a man with large typical chains in the neck admitted to hospital on June 14th, 1920. Gland puncture showed numerous trypanosomes and filariae. On June 15th 0.6 gram neo kharsivan was injected intravenously; on the 17th 12 c.cm. of cerebro spinal fluid were drawn off by lumbar puncture. The cerebro spinal fluid on examination showed trypanosomes.

Case 31.

Wana, a man with large typical glands, was admitted on June 19th, 1920, gland puncture showed trypanosome infection. Neo kharsivan 0.6 gram was administered intravenously on June 22th, and on the 23rd when 12 c.cm. of cerebro-spinal fluid were drawn off, prior to intrathecal medication, it was found to contain living trypanosomes.

The next case is, to our mind, more striking, and we think proves conclusively our theory.

Case 34.

Asumani, a boy with typical enlarged glands on both sides of the neck from which trypanosomes could easily be recovered, was admitted on August 3rd, 1920. On August 5th he received 0.6 gram of neo-kharsivan, and as his home was far away he was kept in hospital. He was given no intraspinal treatment. Towards the end of October this boy reported difficulty in walking and general debility; on examination of his cerebro-spinal fluid living trypanosomes were found, while none were discoverable in the blood or in his cervical glands. His glands were again examined at the time of writing this report (December 24th, 1920), and still nothing could be found.

(It should be noted that in none of the above cases was there any chance of reinfection.)

While there is no doubt that in healthy individuals drugs administered intravenously may find their way into the cerebro-spinal fluid,¹ we are of opinion that the choroid plexus mainly and other structures concerned in the diffusion of the plasma and the cerebro-spinal fluid, become obliterated at a clinically early stage; the result is we have two foci of disease—the blood or lymphatic stream and the cerebro-spinal cavity—and to get rid of the disease it is necessary to attend to both these foci. That the permeability of the meninges is seriously affected at an early stage of the trypanosome infection is evidenced in the living by early lymphocytosis of the cerebro-spinal fluid, and in the dead by microscopical examination of the meninges, the latter being at times the only evidence of the disease; and when such nervous alterations have occurred, blood medication, however active, will fail to influence the course of the disease.

Many authorities are agreed that the administration of a dose of salvarsan, neo salvarsan, or atoxyl is sufficient to sterilize the blood in a surprisingly short time; the patient is thus looked upon as temporarily cured, but within a variable period of time nervous symptoms appear, and the infection goes on unchecked, the patient eventually dying. Excluding reinfections, two theories have been put forward to account for this: (a) That there are resistant forms, and (b) that certain trypanosomes are protected from the action of the medicament by their position in the organism, for example, bone marrow, central nervous system.² While the possibility of the trypanosome in forming new races cannot be doubted, and is by some considered as unlimited,³ we are more inclined to think that the second theory is the more probable, from the arguments we have set forth.

It also appears very probable to us that, if we can obtain a case of trypanosomiasis in its early stages, one single dose of salvarsan or any other allied drug may be enough to cure once for all the patient from the infection, and this may account for those cases which have been recorded as cured, and in this category we are inclined to place two of our own cases (Case 14 and Case 28), who only received an intravenous injection, and who, up to now, are enjoying excellent health. These cases were originally kept as controls, and that is why they had no salvarsanized serum given them.

The detection of early cases is a difficult affair, except perhaps in Europeans where a history of having been bitten by a fly in a glossina-infested area, may be obtainable. Even then the assertion that the case is an early one is distinctly risky, as one cannot be sure of the presence or otherwise of the trypanosome in the cerebro-spinal fluid unless the latter is examined, and once this has been decided upon, as it should be, the salvarsanized serum can be given at the same time.

An injection into the thecal cavity, done with the usual antiseptic precautions, does not show any untoward symptoms or sequelae; we have noticed that the injection of salvarsanized serum is usually accompanied with a slight rise of temperature to 100° or 101° F., pains in the back along the spinal column—most marked in the region of the anus—vomiting, and slight diarrhoea. These symptoms disappear in a day or two, after which time the patient is discharged.

The course, therefore, of the trypanosome in the human body is, first, its passage into the blood, subsequently followed by glandular enlargement, usually in the cervical region; secondly, its passage into the central nervous system, where soon it produces lesions of the meninges, which shut it off from its parent in the blood. The curability or otherwise of the disease, therefore, depends to a great extent on how far the nervous lesions have advanced; if these are far advanced the infection ceases, so to say, to be trypanosomiasis and becomes a chronic

nervous disease, ending in death. There seems to be, though, an appreciable period of time between the passage of the trypanosomes in the cerebro-spinal fluid and the onset of nervous symptoms, and it is possible, we think, to greatly improve, and perhaps cure, the patient during this time; it is only when irremediable and irreparable damage has been done to the central nervous system that the case is hopeless.

From an analysis of cases thus treated (from these we exclude those which have been done during the last three months) it appears that the patients after the treatment start putting on weight, feel much better and are generally changed individuals. They are able to do physical work, not excluding porters' work, which, we might add, consists in the carrying of loads varying between 40 and 50 lb. for an average distance of about ten or fifteen miles. Another patient of ours, treated in April (Case 23), aged about 60, cycled in about thirty miles one morning for re-examination—a feat for him, as he stated he had been unable to ride a bicycle for at least a year before treatment.

Analysis of Cases of Sleeping Sickness treated with Neo-kharsivan, Atoxyl, or Plain Serum.

N=Neo-kharsivan; A=Atoxyl; S=Plain Serum.

Notes.—Case 1 died of sleeping sickness. Case 3 (the date of who treatment is uncertain) disappeared; presumably dead. There are no records of Cases 5 and 9; ? died of sleeping sickness. Case 6 died of sleeping sickness. Case 10 died of sleeping sickness. Case 33 died of pneumonia. Case 34 is under treatment; referred to in report. Case 43 died of pneumonia, October 25th, 1920. Case 43 died one day after admission; no treatment given. Case 46 was a European.

Duration of Cases up to December 31st, 1920, without any Symptoms or Microscopical Findings.

Case 2	27 months
" 4	Av. 21 "
" 7	Av. 18 "
" 8	Av. 15 "
" 9	Av. 15 "
" 10	14 "
Cases 11 to 15	13 "
" 16 to 25	8 "
" 26 to 29	7 "
" 30 to 33	6 "

Cases in which the Cerebro-spinal Fluid was Positive.

Deaths and Causes.

Case 1 ...	Sleeping sickness.
" 3 ...	Disappeared; presumably dead.
" 5 ...	Sleeping sickness (no records).
" 9 ...	Sleeping sickness.
" 10 ...	Sleeping sickness.
" 33 ...	Delayed CHCl ₃ poisoning; marked mediastinal changes at necropsy.
" 42 ...	Pneumonia.
" 43 ...	Died on admission.

While it may be early to state positively that the present treatment promotes definite cure, we cannot help but feel optimistic in the face of the results we have obtained. Several of our cases have gone well beyond a year with one dose of treatment, and they have all invariably improved in health and no trypanosomes have been found, though they have been subjected to repeated and careful investigations.

Most of our cases have been treated with Burroughs Wellcome and Co.'s neo-kharsivan, a few cases were also treated by atoxyl, the object being to find out which is the more efficient drug. We also mean to use other drugs such as galyol and also tartar emetic, and we hope to be able to publish during the next year (1921) comparative results of the various drugs used.

Experiments are also being made to see whether the results we have up to now obtained may not be due to the formation of trypanolysins or other antibodies. That the trypanosomes give rise to specific lysins was suggested by Louis Martin and Henri Darre, who attributed the fever to the massive destruction of the parasites by trypanolysis, and who showed that the blood of patients obtained at the onset of fever had a very marked trypanolytic power both *in vitro* and *in vivo*. We have therefore treated one or two well chosen cases with plain serum—that is, the serum from one of our treated cases was injected into the blood and cerebro-spinal fluid of another sleeping sickness patient; up to now it is much too early to form any opinion.

Conclusions.

1. Of 56 cases treated up to now, 8 are dead. Of 6 of these we have records, and of these 6 only 3 died of sleeping sickness, the others dying of an intercurrent disease, favoured, may be, by the trypanosome infection.
 2. All the remaining cases are doing well, some (21) have only been treated during the last six months and so are excluded from this paper, though included in the index of cases.
 3. The drugs tried so far have been neo kharsivan most extensively, and to a less extent atoxyl, but all that has been said in this paper refers mainly to neo kharsivan.
 4. Plain serum treatment is also being tried in a few carefully selected cases. In advanced cases we are trying direct spinal medication; so far the results are uncertain—one case treated thus died; another, under observation, in whose spinal cord 0.003 gram neo kharsivan was introduced, seems to present a certain amount of improvement.
- Finally, we wish to express our thanks to Dr. C. A. Wiggins, Principal Medical Officer of this Protectorate, for his assistance and encouragement in carrying out these investigations and for his permission to publish this report.

THE VIRULENCE OF DIPHTHERIA-LIKE ORGANISMS.

A NOTE ON THE INTRACUTANEOUS TEST.*

BY

A. J. EAGLETON, M.D. LOND.,

AND

E. M. BAXTER, M.Sc. SHEFFIELD.

For testing the virulence of diphtheria like organisms, Zingher and Soletsky¹ described a method of intracutaneous injection which was a modification of that originally described by Neisser. They advocated the method on the grounds of economy, and stated that in 60 cases it gave the same result as the subcutaneous method. These authors usually tested four strains on each pair of guinea pigs.

We have been using a similar test for some months, and are submitting our experience of it in the hope that it may prove useful to the many public health pathologists in England who are working in the same field. The modifications we have introduced are as follows:

1. Standardization of inoculum by opacity.
2. Inclusion of a known virulent strain in each test.
3. Injection of control animal on the preceding day.
4. Administration to the unprotected animal of a "following dose" of antitoxin of such a size that the skin reactions are not obscured while the life of the guinea-pig is saved.

The technique of the test is as follows:

Two guinea pigs are used for each test; both must be partially white.

Protecting Dose.—One animal is given 500 units of diphtheria antitoxin by intraperitoneal injection on the day preceding the test. This animal acts as a control.

Preparation of Inoculum.—The test strains and a known virulent diphtheria bacillus are grown eighteen hours on Loeffler's slopes, emulsified in saline, diluted and standardized by opacity so that the suspension contains approximately fifty million organisms per cubic centimetre.

Injection of Suspensions.—White-haired portions of the guinea-pigs are depilated with calcium sulphide paste, and into corresponding skin areas of the two animals is injected 0.2 c.cm. of each suspension. The injections are strictly intradermal and at least half an inch apart. On each pair of animals we usually test eight or ten strains, including the control virulent.

Following Dose.—Four or five hours later the animal which was not given a protecting dose on the previous day receives 125 units of diphtheria antitoxin intraperitoneally.

Readings are taken for the next three days.

In the case of a virulent diphtheria bacillus the control animal shows nothing or a faint transient flash; the other animal shows a definite rose-red swelling which becomes more marked at each successive reading, and may terminate in slight necrosis. An avirulent diphtheria-like organism gives a negative result with both animals. If the test culture is contaminated with streptococci the result may be obscured by a reaction in both animals, but this does not always happen.

The advantages of the test are:

1. Economy of animals, as both survive.
2. Owing to the variability of growth shown by different strains, standardization by opacity is preferable to the use of a certain proportion of a slope culture (as in the American method).
3. Reliability. We have had the opportunity of comparing only a limited number of strains by the subcutaneous injection method; so far the agreement is satisfactory.

MUCH is hoped in Germany from the regulation, made at the beginning of 1921, prohibiting the exploitation of Wassermann's test by persons unrecognized by the health authorities as competent to carry it out. A further precaution to secure a reliable Wassermann test is the decree that only those extracts must be used which have been tested at the Institute for Experimental Therapy, conducted by Professor Kolle at Frankfurt a. Maine.

THE LINGUAL APPLICATION OF IODINE AS A PROPHYLACTIC IN CEREBRO-SPINAL MENINGITIS AND INFLUENZA.

BY

J. A. TAYLOR, M.B., D.T.M.,

SENIOR MEDICAL OFFICER, UGANDA PROTECTORATE.

The treatment of cerebro-spinal meningitis by the application of iodine to the tongue led me to try it also in this manner as a prophylactic for the same disease, and for influenza during the epidemic in the Mbarara and Kigezi districts, Uganda, in 1918-19.

In both diseases the site of infection appears to be the respiratory passages, possibly most frequently the pharyngeal tonsils, and my assumption was that the iodine would to some extent cause disinfection of the mouth, throat, and tonsils, and thus prevent or reduce the intensity of the disease. Moreover, the iodine increases the flow of saliva which in itself is prohibitive to the growth of the organisms, and a four-fold action is thus brought into force:

1. The local disinfectant action on application near the site of infection.
2. The action of the increased flow of saliva.
3. The action of the iodine after absorption.
4. The excretion of the iodine in the saliva and respiratory passages again acting as a disinfectant.

Ordinary tincture of iodine (B. P.) was mixed with an equal part of native honey, and, in the case of cerebro-spinal meningitis, instructions were given that two or three drops of this mixture should be placed on the tongue of contacts two or three times daily. A large number of cases of cerebro-spinal meningitis among natives was being reported monthly throughout the district, and all that can be said as to results is that no contacts who used it developed the disease, and the number of deaths reported fell in a few months from an average of 100 to an average of 40 a month. Strict isolation of contacts, however, was in force before the use of the iodine, and it was unusual for contacts to become infected after segregation. It is therefore doubtful whether the iodine had any effect, but the natives themselves had great confidence in its efficacy.

In influenza the results appeared to be more definite. No attempts could be made to distribute an experimental medicinal prophylactic among the natives generally; distribution was therefore confined to ten Europeans, about 100 Asiatic clerks and shopkeepers, and a few native chiefs, clerks, and servants of Europeans. The iodine was used in the same manner, but with the recommendation that applications should be made at least every three hours, or more frequently if convenient. This was in November, 1918, when the first suspicious case of influenza occurred near Mbarara. Towards the end of December the disease became prevalent throughout the district, and nearly every person, except some of those to whom the iodine had been distributed, suffered from the disease in a more or less severe form. Among the Europeans, who all used the iodine more or less regularly, no case occurred, although many were in daily contact with persons suffering from the disease. With regard to the Asiatics and natives to whom the iodine had been distributed, it was impossible to ascertain in most cases with what regularity the prophylactic had been used, but a large number escaped infection altogether, and others had the disease in a mild form with no complications. None of the natives using it died; the death rate among those who did not was high. Among the Asiatic population also there were no deaths, as compared with a mortality rate of 6.53 per cent. throughout the Protectorate.

Many instances occurred which appeared to prove the efficacy of the prophylactic and the value of frequent applications. In one family the father, who was in daily contact with influenza cases in all stages, used the iodine regularly and escaped altogether, while the remainder of the family, who had used it less regularly, had mild attacks. In another case, one child appreciated the taste of the mixture so much that he managed to obtain frequent applications and escaped infection, while all the rest of the family had slight attacks.

I have refrained from publishing these notes until now as I considered the results far from convincing. During

the past year, however, I have had the opportunity of seeing several records of the use of iodine taken internally both in the treatment of and as a prophylactic for influenza. Possibly the iodine after lingual application instead of acting as a local disinfectant had its chief action through absorption, but personally I am convinced that its use saved several lives. Moreover, during the past year I have had the opportunity of using it with contacts of isolated cases of influenza, and all have escaped the disease. Possibly painting the tonsils and the back of the throat with iodine would be of greater value, but I consider this would be a too elaborate and unpleasant procedure to be adopted as a general prophylactic with regularity, whereas the placing of a few drops on the tongue is a very simple matter and may prove as efficacious if done with sufficient frequency.

I wish to thank Major C. A. Wiggins, Principal Medical Officer, Uganda Protectorate, for permission to publish this paper.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

BILATERAL HYPOGLOSSAL PALSY DUE TO GUNSHOT WOUNDS.

A SIMULTANEOUS wounding of both hypoglossal nerves unaccompanied by any other serious injury, must be an uncommon event. I have short notes of two such cases, and, though the records are imperfect and may show obvious defects from the neurological point of view, yet they may possess some interest.

CASE I.

Lance-Corporal S., wounded September 15th, 1916. A small fragment of shell has passed transversely across the mandibular region. The wounds of entry and exit are both small, and correspond in position on the two sides. They are situated immediately below the mandible at the junction of the middle and posterior thirds of the horizontal ramus. Both hypoglossal nerves are paralysed. The patient cannot thrust his tongue forward, but can deviate it slightly from side to side, though not sufficiently to touch his cheek. He can dorsiflex the tongue, though not to a full degree, and can retract it fully towards the pharynx. The movements appear to be performed by the pharyngeal and extrinsic muscles, the tongue itself being almost inert except for the power of dorsiflexion. There is no loss of tactile sensation or of taste for salt in either half of the tongue. His pronunciation of the letters of the alphabet is given below.

CASE II.

Private G. N., wounded by rifle bullet, October 16th, 1916. The bullet has passed transversely below the lower jaw. The entry and exit wounds are small and symmetrically placed on the two sides immediately below the mandible, a quarter of an inch in front of the angle. The movements of the tongue are similar to those in Case I.

Pronunciation of the Letters of the Alphabet.

	CASE I.	CASE II.		CASE I.	CASE II.
A	ah	ah	N	en	en
B	bē	bē	O	o	o
C	cē	cē	P	pē	pē
D	vē (?)	dē (?)	Q	hōd	hew
E	ē	ē	R	ār	ār
F	eff	eff	S	ess	ess
G	vē (?)	dē (?)	T	tē	tē
H	hitch	nitch	U	oo	jew
I	i	i	V	vē	vē
J	wri	dē-a (?)	W	bubbleoo	doublejew
K	kē	kē	X	ex	ex
L	ell	ell	Y	wi	wi
M	em	em	Z	reb	zeb (?)

Regarding the vowels, neither of the patients could pronounce A, as in day, or a long E, while in Case I U could not be pronounced as jew. In Case II the only consonants which were quite impossible were G and J, while in Case I D, K, Q, T, W, and Z also offered complete stumbling-blocks. In Case II the pronunciation of D was doubtful, there being a very small sound of the consonant, which was overshadowed by the forcible expiratory sound which accompanied it, and careful attention was required to appreciate the "D." Speaking generally, there were but few articular sounds which were quite impossible, though there was a general lack of distinctness in the enunciation, while excessive expiratory efforts were brought into use in the endeavour to give precision to the individual syllables and words.

HAROLD BURROWS, F.R.C.S.

Southsea.

Reports of Societies.

THE TREATMENT OF TRYPANOSOMIASIS.

At the meeting of the Royal Society of Tropical Medicine and Hygiene on May 20th, the President (Professor W. J. R. SIMPSON) in the chair, a paper was read by Dr. CLAUDE H. MARSHALL on "A new method of treatment of trypanosomiasis," embodying the results given in an article by himself and Dr. Vassallo which is printed in full in this issue of the BRITISH MEDICAL JOURNAL (p. 773). Dr. Marshall's previous report on the treatment of sleeping sickness by combined intravenous and intrathecal injections of "salvarsanized serum" appeared in the BRITISH MEDICAL JOURNAL of May 22nd, 1920, p. 702. A former patient, the only European patient, to whose case Dr. Marshall referred in detail, was present at the meeting, and was congratulated by the President and others on his appearance of excellent health. After relating particulars of the technique, the cases, and the results, substantially as in the paper published in this issue, Dr. Marshall went on to suggest that the curative effect of the serum treatment resulted from the formation and action of some form of trypanolysin. If the theories of Dr. Vassallo and himself were correct, there was no reason why animal serum should not be used for treatment, why some degree of prophylaxis and immunity to trypanosomiasis should not be obtained, and why early diagnosis should not be effected by some form of complement fixation test. Dr. Vassallo was now carrying out experiments on these lines. The line of treatment adopted for human beings might probably be applied to animals; the cure of "fly" disease in horses and cattle should prove of great economic value, but he appealed for the assistance of the veterinary branch of medical science in such researches, in particular for the co-operation of a veterinary officer in future work.

The PRESIDENT said that he considered the investigation to be one of the most important that had ever been placed before the Society. If the results described were maintained in the future and were confirmed by further investigation it opened up a new and brilliant era for the prevention and treatment of trypanosomiasis. What that meant for humanity they could imagine by recalling the vastness of the region infested by the tsetse fly. Dr. Marshall's observations were not carried out on the lower animals, but on men and women, and the results certainly seemed to indicate a reduction in the mortality in one form at least of the disease. Dr. Marshall had rightly excluded 23 cases treated for less than six months, but that left a series of 30 cases, of which it was found that 22 (or 73 per cent.) were alive and well after more than six months, while of 13 cases treated for over a year 9 (or 69 per cent.) were alive and well. This was putting the successes at their lowest. It remained to be seen whether the same favourable results could be obtained in the Rhodesian type of trypanosomiasis. He saw no reason why this should not be, seeing that treatment was based on a scientific foundation. He hoped that some movement might be inaugurated for putting this treatment to the test on a larger scale. He agreed that the veterinarian should come in to assist, and other scientific workers also, but a Rockefeller was badly needed to help financially.

Professor W. D. HALLIBURTON dealt specially with a point referred to him by the President—the reason why in cerebro-spinal trypanosomiasis it was of no use injecting anything into the blood. The cerebro-spinal fluid, he said, was really a secretion not a leakage fluid from the blood. It was sometimes called the lymph of the brain, but that was a very slipshod expression, for in lymph there was always a possible passage of materials in both directions, from blood to lymph and lymph to blood, whereas in the case of this particular fluid there was a passage of only a constant saline material which maintained the normal osmotic pressure which was beneficial for the life of the nerve cells, and in disease as well as in health the choroidal cells maintained a stalwart barrier against the entrance of foreign material which might be circulating in the blood. Only one or two volatile materials, of which alcohol was the best known, got through. It was a matter of congratulation to Dr. Marshall and his colleague that they had found a material which was fatal to the parasite but not fatal to the host.

Dr. P. MANSON-BAHR asked whether the invasion of the cerebro-spinal fluid was necessary to produce the sleeping sickness; he held that it was not. He had one case from the Congo, first infected in 1916; there was little doubt that the patient had trypanosomiasis, but during five years, only on one occasion had trypanosomes been found in his blood. His state of trypanosomiasis was most typical, and yet for three years now there had been no direct scientific evidence for the condition. In another case under his observation Dr. Marshall's and other treatments had been tried without making the smallest difference to the number of trypanosomes found in the blood. In estimating the effect of drugs on trypanosomiasis the fact must be taken into account that the protozoa had a periodic habit in the blood; in the case in question they reappeared every three weeks, the man usually having about sixteen trypanosomes for every 200 leucocytes. The speaker held that there was no reason why trypanosomiasis should not be a self-limiting disease, and the wonderful cures reported might be due to the nature of the body resistance rather than to any drugs injected.

Dr. G. C. LOW supported the criticisms of Dr. Manson-Bahr, and asked what foundation there was for supposing that a few cases treated up to thirteen months had been cured. He did not think that a case could be regarded as cured until after a period of at least three years. Sleeping sickness had probably become more chronic in form in Uganda since he himself began the study of it there twenty-one years ago, and this was the more reason against being over-definite in the description of results as cures after so short a period of time.

Dr. W. T. PROUT refused to take such a pessimistic view as Dr. Manson-Bahr and Dr. Low, and he thought that the indications were that Dr. Marshall's use of the word "cure" was justified.

Dr. C. F. HANFORD thought that the cases which filtered through into our hospitals at home could not be classed in the same category as the cases dealt with in the country of their origin, and this might account for the differences of opinion among observers.

Dr. MARSHALL, in a brief reply, said that because quinine and salvarsan had occasionally no effect in malaria and syphilis respectively, that was no reason why they should not remain as routine treatment, and he thought that the same principle held good in the matter under discussion. Dr. Low had suggested that it was too soon to say that the patient who had been brought forward that evening was cured, but at any rate he did not look as though he were troubled by sleeping sickness or anything else! The European had a higher resistance to trypanosomiasis than the native. Dr. Marshall added that he and his colleague in Uganda would very much welcome further tests.

Colonel R. H. ELLIOT said that a number of members of the Society who were interested in varying degrees in Dr. Marshall's work felt that an opportunity for the further continuance of that work ought to be given. Some representations should certainly be made to the Colonial Office in favour of a complete investigation, not only of human but of animal trypanosomiasis. They all knew the anxiety which the disease had given to the Government of Uganda, and the enormous advantage which would accrue if the treatment proved effective.

Sir HUGH CLIFFORD, Governor and Commander-in-Chief of Nigeria, said that the tropics seemed to be differentiated from the rest of the world by their subjection throughout recorded ages to the domination of insect-borne disease. This fact had determined their history to a great extent and the character of their people. It must be admitted that Dr. Marshall's discoveries called for further investigation, and experiments should be carried out systematically and scientifically by the ablest officers. He would personally address the Secretary of State on behalf of the Government he represented, urging that this important discovery should be taken up scientifically by the medical department in Nigeria, and if it was going to cost a few thousands his Government would not grudge the expenditure in so good a cause.

Dr. JENSEN then proposed and Colonel ELLIOT seconded a motion that the Society was of opinion that every facility should be given for the furtherance of Dr. Marshall's work and investigations. This was carried unanimously, and it was understood that the resolution would be conveyed to the Colonial Office.

FIBROUS AND MUSCULAR ATTACHMENTS OF
THE VAGINA.

At a meeting of the Obstetrical Section of the Royal Academy of Medicine in Ireland, on April 29th, with the President, Dr. E. HASTINGS TWEDDY, in the chair, Dr. LOUIS CASSIDY read a paper on the fibrous and muscular attachments of the vagina. In the course of his communication he showed (by various lantern slides) that the lower two thirds of the lateral walls of the vagina were in close apposition with the levatores ani muscles. Interposed between the lateral walls of the vagina and these muscles was a distinct layer of fascia—a portion of the visceral layer of the pelvic fascia—which gained a very definite attachment to the walls of the vagina. This layer was clearly demonstrable, and was intimately blended with the fasciculi of the levatores ani muscles. When followed forwards immediately below the neck of the bladder this fascia was found to be continuous with the pubo-rectal ligaments, whilst behind it passed into the fascia surrounding the rectum. The surface of this layer of the fascia, which rested upon the levatores ani, sent prolongations into the muscle to blend with its sheath, thereby indirectly supporting the vagina. The anterior and posterior fascial supports of the vagina resolved themselves into the attachments between the fibrous covering of the posterior wall of the urethra and the anterior fibrous sheath of the rectum behind. The attachment between the wall of the urethra and vagina was a very close one, the structures being morphologically continuous, and was associated with the presence of the dense mass of fibrous tissue which in this region occupied the space left by the disappearance of the female prostate; it was impossible to separate the two structures in their lower two-thirds, the knife had to be used. The union of the lower three-fourths with the rectum and anal canal was much less intimate and permitted of easy separation. This relationship between the rectum and vagina was much strengthened at the junction of the rectum and anal canal by the presence of the perineal body. This structure was a wedge-shaped mass consisting of fibro-muscular tissue, and was about one inch in depth, the base of the wedge lying at the skin surface (Tandler).

The vagina pierced the two layers of the triangular ligament, and consequently received firm support from this structure. The muscular attachments of the vagina were solely comprised by the levatores ani. A transverse section through the pelvis of a female child aged 19 months, and taken through the middle of the true pelvis, demonstrated the attachments of fibres of the levatores ani muscles to the lateral walls of the vagina. This relationship was denied by such eminent authorities as Halban and Tandler, as well as Cruveilhier. In conclusion, the writer was convinced that the prevention of a hernial protrusion of the anterior and posterior walls of the vagina depended on the lateral support it received from the pelvic fascia and the integrity of the perineal body. He considered this latter structure of paramount importance in the mechanical support of the female pelvic diaphragm. There was one other point to which attention might be drawn—the presence of the transversalis coli, or Mackenrodt's ligaments. These structures would be readily recognized in transverse section through the pelvis of a young female child. That these ligaments did very materially support the upper third of the vagina there could not be much doubt.

Dr. GIBBON FITZGIBBON agreed with Dr. Cassidy about the value of the pelvic fascia. Referring to the parietal and visceral layers, he thought that anatomists did not go far enough. He was of opinion that the former was merely the covering of the levator ani muscle. The actual supports of the vagina were well shown by Dr. Cassidy. He thought there was just as much fascia round the parametrium as in Mackenrodt's ligaments. The parametrium was all muscular and contained very little fascia, and this was the real support of the vagina.

Dr. BETHEL SOLOMONS was greatly struck by the fact that in Dr. Cassidy's ardent researches it had been found that Mackenrodt's ligaments were not the only supports of the vagina. He believed that in further research the essayist would find that Mackenrodt's ligaments were probably the most important but not the only supports of

the pelvic viscera. The old argument, that in cutting through these ligaments the fact that the uterus descended proved that these were the only supports, did not hold water, any more than the fact that after the removal of one limb the body being supported by the other proved that the body was supported by one lower limb. He asked the essayist what constituted the pillars of the bladder which were so useful in acting as supports for the bladder in the operation for the cure of cystocele. Did he consider them to be a portion of the pubo-coccygeus muscle with or without fascia, or possibly the detrusor muscle of the bladder?

The PRESIDENT regretted that Dr. Cassidy had not gone further and demonstrated the attachments of the uterus, but hoped he would bring it forward on a future occasion. In his (the President's) opinion these fibrous attachments were the supports of the uterus as well as of the vagina. The Master of the Rotunda (Dr. FITZGIBBON) was right in saying that the strands of fibrous tissue in the pelvis ran in every direction, and different names—Mackenrodt's ligaments, utero-sacral ligaments, etc.—had been given to different bundles of these. The theory of the pelvic fascia was fascinating. He believed that the uterus was the origin of these strands, which grew out from it in all directions, and they might fitly be described as "uterine tendons." These tendons or ligaments contained muscle, and were under the control of the uterus, and, he believed, were its sole support.

Primary Carcinoma of the Vagina.

Dr. GIBBON FITZGIBBON showed a specimen of primary carcinoma of the vagina, from a patient aged 42, 7-para, whose last pregnancy, four years ago, was normal. Her menses were regular and normal, and she was quite well up to two months ago, when slight bleeding from the vagina started and continued. On examination, the vulva and perineum were quite healthy. From the right lateral fornix of the vagina there was an ulceration extending slightly on to the posterior wall and down the lateral wall to about an inch and a quarter from the hymen. The ulcer looked very clean, the surface a little irregular and soft, and the edges fairly sharp. There was no evidence of rectal or bladder involvement. The ulcer ran close up to the cervix, but did not encroach on its mucous membrane. By the rectum a hard nodule could be felt under the ulcer, extending out towards the pelvic wall, but mobile. The surface of the ulcer was removed with the curette and some pieces of the edge cut away for examination.

The pathological report was that it was a definite cancerous growth, showing dense masses of cells.

First, by the abdomen, the ordinary lines of a Wertheim's hysterectomy were carried out, until the whole of the vaginal fornices were quite freed. The internal iliac vessels were cleared and tied at their origins. The patient was then put into the lithotomy position and the vagina divided just inside the hymen all round and separated up, taking as much of the tissue in the ischio-rectal fossae as possible, until the detached upper part was reached, when the whole mass of the vagina and uterus was removed through the vulva. The edges of the vulva were fixed with a few stitches and the rest of the operation done by the abdomen. The pelvic peritoneum was closed over a gauze packing. The patient was severely affected by shock, but responded well to a coffee enema, followed by small saline enemata during the next twenty-four hours, and made an uninterrupted recovery, the abdomen healing perfectly.

A few days before operating on this case Dr. FITZGIBBON operated on another patient in whom the cancer was also primary in the vagina and situated in the lower half, just coming down to the level of the hymen. There was a mass extending out to the ischio-rectal fossa and a hard ring round the vagina, but the ulceration was only lateral. In this case he removed the whole vagina from the lesser labia, the edge of the perineum, and the external meatus of the urethra up to the vaginal fornices, and taking the vaginal portion of the cervix. Of the two operations he considered the former was the easier. There was less haemorrhage, owing to the internal iliac vessels having been tied, and the removal of parametrium above the fornices was much more complete and simple. Should he have to operate on cancer of the vagina again, he would do the operation—including the removal of the uterus—in three stages, as in this case. It was surprising how little haemorrhage occurred, only two or three small vessels were cut, but there was rather profuse venous

bleeding for a time, and this was avoided in the case with hysterectomy.

Dr. SOLOMONS, Dr. MADILL, and the PRESIDENT spoke and Dr. FITZGIBBON replied. Dr. R. E. TOTTENHAM showed a new type of pelvimeter.

RENAL DIABETES.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow, held on April 15th, the PRESIDENT occupying the chair, Dr. ADAM PATRICK described a case of renal diabetes. In the normal person, he said, the blood sugar varies from about 0.07 per cent. to about 0.15 per cent., or rather more. If the latter concentration is exceeded, sugar appears in the urine. In healthy persons it is difficult to raise the blood sugar above this level. In the diabetic the threshold concentration is habitually exceeded, and readings of 0.25 per cent., or much higher, may be obtained. A single reading of this kind is enough to establish a diagnosis of true diabetes. Sugar may also appear in the urine if the renal threshold is lowered, even if the blood sugar does not exceed the normal. In the normal subject the limit of sugar concentration is reached in about an hour, whereas in the diabetic the maximum is not reached for two or three hours. The case described, that of a man aged 39, was found to have glycosuria on examination for life insurance, although five years before there was certainly none. His health had been good, save for an attack of haematuria (cause unknown) ten years before. At the latter date there were no symptoms. Treatment on the lines suggested by Allen was instituted without great success, and the urine only remained sugar-free on a diet approaching starvation. In hospital it was found that on a very restricted diet, and with the blood sugar reading only 0.05 per cent., there was a trace of sugar in the urine; on ordinary diet there was abundant sugar in the urine two and a quarter hours after dinner, although the blood sugar was only 0.114 per cent. Tested by administration of 25 grams of glucose after a sixteen hours' starve, the blood sugar curve was normal in type. The name "renal diabetes" is applied because the glycosuria appears to be due to a defect in the kidney.

Professor MUNRO KERR read notes of a case of resection of a double uterus, followed by two full-time pregnancies. He also showed the uterus, which had been removed after a Caesarean section. The diagnosis lay between an extra-uterine pregnancy, a myoma contracting a uterine pregnancy, and a pregnancy in the horn of a double uterus. Matters were cleared up by the expulsion of the ovum from the right horn of a uterus bicornis. The patient had a second miscarriage at a later date from the same horn. Both miscarriages occurred at the third month. The resection of the uterus (uterus bicornis unicollis symmetrical) was done seven months after the last miscarriage. A V-shaped wedge was removed and the two halves of the uterus carefully stitched together. Pregnancy followed soon afterwards and proceeded to full time. A living child was delivered with forceps, but died owing to injuries sustained at birth. The uterine scar was found by manual examination to be quite satisfactory. Some months later the patient again fell pregnant, and at full time Caesarean section was performed and the uterus removed. Professor Munro Kerr demonstrated the uterine scars on the anterior and posterior walls of the uterus. These, especially that on the anterior wall, were satisfactory, but there was a gutter-shaped indentation in the posterior wall over which the placenta was attached. Microscopically a great deal of connective tissue was seen in the scars, particularly in the posterior one. The operation had been done on one or two occasions in Continental clinics, but, so far as Professor Munro Kerr knew, not previously in this country. The indication for the operation was the repeated miscarriages, which seemed to be common in this form of malformation.

Dr. JAMES HENDRY described a case of amenorrhoea following severe trauma. In May, 1919, the patient reported three months' amenorrhoea without other signs of pregnancy. Her appearance suggested thyroid insufficiency, and there was no sign of pregnancy. The disturbances suggesting thyroid insufficiency were only of recent date, and her health previously had been good. Treatment with thyroid extract was prescribed and continued for a

few weeks without any improvement, and, in fact, the patient became stouter and more drowsy and apathetic. On again reviewing her history in detail, it was discovered that a few weeks before the patient's first missed period she had fallen in the street on the back of her head during frosty weather. Next day her sight was affected and vision was almost lost, but had almost completely returned. Dr. Hendry then thought of a possible lesion of the pituitary gland, and administered orally tablets of pituitary (whole gland) without any success. By June, 1920, a fairly well developed Frölich's syndrome had shown itself—dystrophia adiposo-genitalis, with lethargy and somnolence; menstruation had returned in scanty form, lasting one day. A skiagram of the skull to show the sella turcica was obtained, and signs of a fracture were marked. The patient, further, could ingest 300 grams of glucose without glycosuria. The oral administration of pituitary gland having proved unsuccessful in most points, pituitrin, administered by hypodermic injection, was tried, with no success. Five months ago, hypodermic injections of autuithin (extract of the anterior lobe) were commenced, and weight was now steadily diminishing, although food intake was normal. Regarding sugar tolerance, 120 grams of glucose now produced glycosuria. The special interest in this case was the association of amenorrhoea with hypopituitary function.

VITAMINS.

At a meeting of the Pathological Society of Manchester on May 11th, Professor E. MELLANBY, M.D., of Sheffield University, lectured on vitamins. He stated that in consequence of two discoveries—namely, (1) that some proteins have a higher food value than others, (2) vitamins—the isodynamic theory of diet must be abandoned. Diet had now become a question not of quantity but of quality, and the whole science of nutrition was in the melting-pot. He traced the history of the experimental work on vitamins, including the work of Hopkins in 1911, when it was proved that animals would not grow on purely synthetic foods.

Describing the three recognized vitamins, (1) antiscorbutic, (2) antiberiberi (water-soluble B), (3) antirachitic (fat soluble A), he explained that they had in common the properties that their chemistry was entirely unknown, that animals could not synthesize them but could only obtain them from the vegetable world, and that they were influenced greatly by the way in which our food was treated. Experiments were described showing the effect of vitamins on calcification processes, the prevention of rickets and the production of good and bad teeth. The consideration of rickets was complicated by the fact that it was a disease of growth. Enlarged epiphyses could be produced by any method leading to a deficiency of calcium in the body. Antirachitic vitamins prevented rickets by allowing the body to make use of the calcium at its disposal. In experiments in which animals were kept on a rickets-producing diet, it was found that, other factors being constant, the more white bread that was given the worse was the degree of rickets, whereas meat had a slight antirachitic effect. Dealing with the controversy concerning the etiology of rickets, Professor Mellanby outlined his grounds for the view that diet was the chief factor, and exercise and sanitation purely subsidiary.

The question of dental caries was then discussed in the light of experiments which showed that the main factor in its causation was not lack of cleanliness but improper feeding during the period of formation of the teeth. The experiments showed that when once good regular teeth were produced in dogs they were much more immune to caries than were irregular, badly formed teeth produced on rachitic diet, and it appeared that fat-soluble A was the all-important factor. The question whether there were more vitamins to be discovered was often asked, but had not been conclusively settled. There were certainly other factors in diet the importance of which was unknown at present. The thyroid gland was examined in dogs fed on a diet containing various fats; when fed on butter, cottonseed oil, or linseed oil, the thyroid was invariably large, and resembled histologically that of Graves's disease, whereas on a diet containing cod-liver oil it was small and histologically normal.

At a meeting of the London Association of the Medical Women's Federation, held on May 10th, with Mrs. FLEMING, M.D., in the chair, Miss E. C. LEWIS, M.S., F.R.C.S., read a paper on "Tuberculous adenitis, its diagnosis and treatment." She confined her attention to the superficial glands, of which the most important were the cervical, which were affected in about 93 per cent. of the cases of superficial adenitis. The reason for their peculiar vulnerability was the importance of their drainage area, since they receive lymph from the teeth, tonsils, tongue, and palate. The age-incidence of cervical adenitis was the same as that of chronic simple enlargement, the greater number of patients being under 10 years of age. All varieties of adenitis were commoner in the female sex. Miss Lewis discussed the clinical picture of these cases and gave a detailed account of important points in diagnosis between tuberculous adenitis, lymphadenoma, and chronic septic adenitis. Other forms of glandular enlargement, such as those due to syphilis and new growths, rarely led to difficulty in diagnosis. In describing treatment stress was laid on the importance of early diagnosis, of clearing-up septic processes in the drainage area of the glands, and of general medical treatment before operation was undertaken. The value of x-ray treatment in cases where glands had broken down was emphasized. A discussion followed, in which Dr. JANE WALKER, Dr. E. CARLING, Dr. R. JORDAN, Miss WHITE, Miss C. KING, and others took part.

Reviews.

INTESTINAL TOXAEMIA.

DR. ALEXANDER BRYCE,¹ the author of *Intestinal Toxaemia or Autointoxication in the Causation of Disease*, hopes that although primarily designed for the medical profession, his clearly written book may, in spite of scientific terms, appeal to a much wider public. Briefly expressed, his view is that of Dr. A. Haig, with the important substitution of "toxic substances" for "uric acid" as the *fons et origo* of numerous human ills. His outlook is therefore on much the same lines as those of Metchnikoff, Sir Arbuthnot Lane, Kellogg, and Danysz, though he is not a slavish follower. He has obviously had considerable personal experience, and read widely in connexion with his subject. The objections to the conception of autointoxication from intestinal stasis are stated from the standpoint of "the pure scientist," for whose "meticulous caution" in accepting conclusions without indisputable proof he expresses sincere admiration. Dr. Bryce frankly admits that there is probably no single disease which can with absolute confidence be identified as the direct product of intestinal toxæmia, and that there are many diseases of such obscure origin that it is tempting to ascribe them to toxic absorption. But he is inclined to regard the evidence in favour of his thesis as circumstantial, and this is duly set out with full references to the work of others. The most convincing proof of the doctrine of autointoxication, he thinks, is to be found in the benefit obtained from the adoption of methods designed to combat it. These are a correct diet with a low protein content, fleshless, and taken in meals three times a day; an action of the bowels after each meal; encouragement of saccharolytic and discouragement of proteolytic bacteria in the intestine; and attention to all the laws of health. A weekly intestinal douche is recommended; the vertigo sometimes attributed during the summer to liquid paraffin can thus be prevented. The objection to paraffin that it may escape from the anus apart from defaecation, can be obviated by taking it once only in the twenty-four hours, and just before going to bed; failure of paraffin to penetrate the faeces can be met by taking bran or agar-agar, the faeces being thus rendered more permeable.

PATHOLOGY OF THE BLOOD.

THE second, enlarged, edition of BURNETT's *Clinical Pathology of the Blood of Domesticated Animals*,² though dated 1917, only reached us on March 21st, 1921. It is intended

¹ *Intestinal Toxaemia or Autointoxication in the Causation of Disease*. By Alexander Bryce, M.D., C.M., D.P.H. London: Andrew Melrose, Ltd. 1921. (Cr. 8vo, pp. 191. 6s. net.)

² *The Clinical Pathology of the Blood of Domesticated Animals*. By S. H. Burnett, A.B., M.S. Second edition, revised and enlarged. New York: The Macmillan Co. 1917. (Med. 8vo, pp. 182; 25 figures. 13s. net.)

for the use of veterinary surgeons and for those who need to know details concerning the common experimental animals. It is arranged as is usual in textbooks of human haematology, and makes full use of data obtained from these sources. The first two chapters are devoted to methods of examination and morphology. In the third chapter details are given of the normal blood counts of various animals. There follow chapters on red and white cell variations; on special, general, and infective diseases; and on diseases due to protozoa and parasites. The illustrations are plentiful and good.

The author is professor of comparative pathology at the New York State Veterinary College, and many of his comments are well worth the attention of clinical pathologists. We do not remember to have seen in any textbook of haematology any such statement as the following: "The liver is the organ best adapted to distinguish, by histological examination, leukaemia and pseudo-leukaemia from generalized sarcoma. The characteristic collections of cells found in pseudo-leukaemia and leukaemia do not occur in sarcoma." Medical literature contains some hundreds of papers devoted to the differences between these diseases, but without any mention of this point, which constitutes an easy and accurate means of distinguishing them. On the other hand, page 13 conveys the intelligence that the standard solution in Sahli's haemoglobinometer is "haemoglobin in glycerin," and the author seems to prefer the very unstable solution of Gower to the Haldane modification or to that of Sahli. Nor can we agree with the statement made of Hodgkin's disease on page 92, that it "cannot be differentiated from lymphatic leukaemia anatomically or histologically if the blood be excepted."

The book is thus uneven in its merits. This is perhaps due to the fact that the author has relied chiefly on the textbooks of Ewing, Cabot, Da Costa, v. Limbeck, Nagel, and Grawitz, none of which have seen new editions for many years.

THE PSYCHOLOGY OF FUNCTIONAL NEUROSES.

THE volume entitled *The Psychology of Functional Neuroses*³ is the outcome of the experience Professor HOLLINGWORTH gained from the study of 1,200 soldiers with persistent neurotic symptoms in the U.S. Army General Hospital. He made systematic observations to determine the intellectual status of these patients by the usual intelligence tests, and upon the results obtained he formulates a theory to account for neurotic manifestations as a whole.

According to Professor Hollingworth, all psychopathologists have missed the essential factor in the genesis of neurotic symptoms, and these are not, as Freud, Jung, and Adler would have us believe, the expression of disturbances in the emotional and instinctive sphere, but are rather the result of intellectual deficiency. In the first place, the author utilizes Hamilton's term, "redintegration," to explain all nervous reactions. "Redintegration," he writes, "is to be conceived as that type of process in which a part of a complex stimulus provokes the complete reaction that was made previously to the complex stimulus as a whole." This concept, which incidentally has been freely utilized by every psychopathologist of whatever school of thought, the author finds to be one "that is significantly descriptive of the psychoneurotic picture, that unerringly identifies the patient, explains the psychogenesis and idiosyncrasy of his symptoms, points the way to therapy and prophylaxis, and is yet intrinsically intelligible, is relevant to the systematic accounts of the average mind, and for which a neural counterpart or correlate is without difficulty conceivable." Thus far psychopathologists will scarcely take exception to the writer's views. He has repeated something with which they are perfectly familiar and which expresses no new idea. When the shell-shocked soldier hears a gun fired or any sudden noise all his previous fear reactions tremors, mutism, and so on—are, of course, apt to return. The explanation here given, however, of these abnormal reactions is so contrary to the concepts of modern psychopathology that it requires much more proof than is brought forward in this volume. These symptoms th-

British Medical Association.

CURRENT NOTES.

New South Wales Branch.

THE annual report of the Council of the New South Wales Branch of the Association states that the membership of the Branch is now 1,180. A conference was held in December, 1920, between the Council and accredited representatives of the friendly society lodges, who had requested that the income limits of lodge members receiving medical benefit should be increased, on the ground of the depreciation in the value of money. The question was raised by the Association of a correlative increase in remuneration for medical officers, based on the same decrease in the value of money and a corresponding rise in the cost of giving medical attendance. As a result of the conference both the prescribed income limits of lodge members and the rates payable for medical attendance were increased. On the occasion of the visit of the Prince of Wales to New South Wales last summer an arch of welcome was erected by the Association, as one of the public bodies of the State, in College Street, Sydney. A description of the arch was given in the *BRITISH MEDICAL JOURNAL* of October 16th, 1920. Very careful consideration was given to the annual report of the Council of the British Medical Association in regard to the question of the possibility and desirability of taking further powers under the constitution of the Association whereby it might become in part a federation of medical bodies, and approval was given at an extraordinary general meeting of the Branch in October, 1920, to a proposal made by the Federal Committee that a representative of the Branches in Australia should be sent to England to attend the conference to be held next July at the Annual Meeting at Newcastle-on-Tyne.

"The Buff Book."

It may be remembered that in the *JOURNAL* of August 28th, 1920, a note appeared under the heading "A Classified Directory," with reference to a proposed publication, "The Buff Book," of which a circular had been issued by a firm styled the Business Telephone Directories Limited. The Central Ethical Committee of the British Medical Association considered that the insertion of a medical practitioner's name in this publication would be objectionable from two points of view. In the first place, the circular made it plain that only selected names would be

published in the directory, to the exclusion of others, for no medical practitioner's name (with address and telephone number) would appear in the "Buff Book" unless he paid a minimum fee of 1 guinea. The second objection arose in connexion with the specimens of type at varying prices, shown in the circular. The first issue of the "Buff Book," dated October, 1920, contained the names of a few medical practitioners grouped under such headings as Physicians (consulting), Surgeons, Surgeons (ophthalmic), and Doctors. In the *SUPPLEMENT* of March 19th, 1921, further mention was made of this directory, with particular reference to a resolution passed by the Executive Committee of the General Medical Council on February 21st, confirming the opinion already expressed by the Central Ethical Committee of the British Medical Association. The resolution was as follows:

That the Executive Committee is of opinion that the insertion of the name of a medical practitioner for payment, whether with or without typographical display, in a list issued to the public, and purporting to be a list of local medical practitioners, which is not open to the whole of the profession without such payment, is not in accordance with the professional standards in respect of advertising, and might be held to bring a practitioner so advertising himself within the terms of No. 5 of the Council's Warning Notices.

A second edition of the "Buff Book," dated April, 1921, has now appeared. On the title-page it is described as a "Classified Commercial Telephone Directory for London." It contains, under the heading "Physicians and Surgeons," some seventy-two medical names, and under the heading "Surgeons" the names of ten practitioners. There are in addition the names of three consulting physicians and one consulting surgeon, one cardiologist and one laryngologist, aurist, and rhinologist. From a communication addressed to the British Medical Association by the proprietors of the "Buff Book," it appears that such medical names as were published in the last edition of this directory were inserted therein without charge. This does not remove the Central Ethical Committee's objection to the publication of a selected list of medical practitioners.

Council Election.

Dr. Frank Radcliffe, Oldham, having withdrawn his candidature, the two remaining candidates, Dr. T. W. H. Garstang (Altrincham) and Mr. F. Strong Heaney (Liverpool), are returned unopposed to the Council for 1921-22 as the representatives of the Lancashire and Cheshire Branch. No voting papers have therefore been issued in connexion with this Group.

India has satisfied the Committee that in most, if not all, of the Indian universities, the prescribed courses of study and examinations in this important branch do not now furnish (in the words of the Medical Act, 1886) "a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice" of midwifery in the United Kingdom. The Committee has communicated its opinion to the Indian universities, and intimated that unless within a year the standard of their requirements in midwifery is raised to a satisfactory level, recognition must be discontinued. The Council is charged under the Act with ascertaining, not the sufficiency of Indian qualifications for the needs of practice in India, but their sufficiency as conferring a registrable title to practise all three branches of the profession in this and other non-Indian parts of the Empire.

Dangerous Drugs Act.

The Pharmacopoeia Committee has had under consideration the Draft Regulations proposed by the Home Office for giving effect to the recent Dangerous Drugs Act. The Committee pointed out to the authorities various particulars, suggested by its members and by other members of the Council, in which amendment of the draft was necessary in the public interest. The chairman and secretary, on behalf of the Committee, have had interviews with the officials concerned, and have by request given information on the subject to a special committee set up by the Home Secretary for the purpose of considering the numerous amendments to the Draft Regulations that had been proposed by medical and pharmaceutical bodies. It is understood that a detailed revision of the original text has been undertaken by the Home Office, with a view to removing, so far as the Act permits, the objections urged against the draft. We have not yet received copies of the regulations as amended, but we understand that effect will be given to our representations.

Therapeutic Substances Insusceptible of Chemical Analysis.

The Departmental Committee appointed by the Ministry of Health to consider and advise upon the administrative measures to be taken for the control of the quality of certain therapeutic substances, such as serums, vaccines, salvarsan, etc., which cannot be tested by direct chemical means, has issued its report. The recommendations give effect, in what appears to be a satisfactory manner, to the wishes of the Council, as expressed in a communication made to the Lord President in 1909. They will be considered in detail by the Pharmacopoeia Committee, and reported on by the Council at this session.

The Dentists Bill.

The Dental Committee also has been active during the recess in considering and advising on the successive drafts of the Dentists Bill during the course of its preparation by the Ministry of Health. As it was made abundantly clear that the bill would have little prospect of passing into law unless its provisions were generally agreed to beforehand by the various bodies concerned, a number of conferences have taken place at which the views of the Council and those of representative members of the dental profession were discussed with the officers of the Ministry. The bill is now before Parliament, and has been read a second time in the House of Commons. While it embodies many of the points on which the Council has from time to time laid stress, it contains one or two that have not yet been considered by the Dental Committee or endorsed by the Council. On these it is possible that the Council may have further instructions to give to its representatives. But the bill makes so great a step towards the removal of the dangerous abuses revealed by the Departmental Committee's Report that, though we may regret its imperfections, we may be prepared to welcome it as an earnest of wider reforms. I may mention that, at the instance of the Lord President, a clause has been introduced to give effect to your resolution of November 27th, 1917, whereby three additional members of the Council, who are registered graduates or licentiates in dental surgery, and members of the new Dental Board, are to co-operate with the Council when dealing with dental matters. The additional or dental members are to be appointed by the Privy Council.

Procedure for Election of Direct Representatives.

No progress has been made by Parliament with the bill for simplifying the procedure at the election of direct representatives to the Council. This is to be regretted, in view of the economies which a suitable change in the law would have made possible.

Finance.

The finances of the Council for the year 1920 show a satisfactory revival as compared with those of the war years. The aggregate surplus of income over expenditure in the General and Branch Councils amounts to £1,960. The considerable expenses incurred in carrying out the inspection and visitation of examinations have been met by a draft on the reserve fund. The number of registrations in the Home List of the Medical Register has risen to a little over 1,100, or almost exactly the same as the numbers for 1912 and 1913. To these must be added 343 registrations in the Colonial and Foreign Lists, as against 53 in 1912 and 65 in 1913. The increase of receipts from registration fees accounts indeed for the greater part of the accrued surplus.

Number of Medical and Dental Students.

The registrations of medical students, which in 1919 rose to 3,420, in 1920 fell to the more manageable number of 2,531; but this number is still higher than in any year prior to 1919. In my opinion, it would be in the interest of sound professional education were the numbers still further reduced. They impose a severer strain, educational and financial, on the schools and hospitals than the necessary recruitment of the profession demands, and in present circumstances the teaching institutions are less able to meet the strain. To raise the educational standard for admission, and to increase the fees for professional tuition, would thus seem, from all points of view, to be prudent and justifiable.

In respect of dentistry, a profession which still needs a large accession of fully trained recruits, the registrations in the *Dentists Register* number 217, as compared with 128 in the year before. They still fall short of the annual number before the war. New dental students, however, number 560. This, though somewhat less than in 1919, is (except for that year) the highest entry yet recorded. The small addition to the ranks of qualified dentists accounts, no doubt, for the unfavourable position of the dental fund. Last year it showed a deficit of £547. Should the Dentists Bill become law, a new position will be created, and comparison with the present statistics will no longer be practicable. It is for this reason that I have ventured to bring to your notice the figures relating to what may be the final stage of the régime which has lasted since 1878. The finances of the Dental Board will have other resources to draw upon and other charges to reckon with, under the new conditions.

The Medical Curriculum.

The procedure which you authorized in November for the investigation of the medical curriculum has been duly carried into operation under the direction of the Education Committee. In connexion with each Branch Council, four subcommittees have been set up, including many men of eminence in the sciences bearing on medicine and in its practice. These have readily lent their valuable aid to the Council's inquiry, and our thanks are due to them for their helpful co-operation. A number of preliminary reports and memoranda on different branches of the subject have been prepared and circulated to members. Before long joint meetings and conferences will be arranged for the co-ordination of these proposals, with a view to the elaboration of considered conclusions and recommendations for presentation to the Education Committee and ultimately to the Council.

Reports on Examinations.

The reports of the Inspectors and Visitors of qualifying examinations in the United Kingdom are now nearly complete. They have still to be considered as a whole by the Examination Committee, which will probably be able to report to you upon the entire cycle in November. But I may here be allowed, by anticipation, to offer my grateful acknowledgements to your Inspectors and Visitors for the conscientious and judicial spirit in which they have

fulfilled their important duties. The like acknowledgements are due to the Inspector of Public Health Examinations, Dr. Bruce Low, who has practically finished his task. The Public Health Committee may be able, at this session, to bring before you some results of the inspection, and to make a beginning with the revision of the rules governing the course of study and examinations for the diploma. The Council will probably think it desirable, as on previous occasions, that the new rules should be circulated in draft form to the qualifying bodies for their observations thereon, before they are finally submitted by the Committee for confirmation.

Disciplinary Cases

The disciplinary cases to be inquired into at this session are few and simple. The Executive Committee proposes that we should take up the first one this afternoon, in order that we may, so far as is possible, economize our time, and be able sooner to deal with the other business on the programme. Under the uncertainty of present conditions, members will probably be desirous of making the session a short one. Let us hope that in November we may be able to meet, for the important business which will then be ready for our consideration, in greater comfort and in more assured peace.

Note of Thanks.

A vote of thanks to the President for his address was accorded by acclamation, on the motion of Sir NORMAN MOORE.

ELECTION OF COMMITTEES.

The following members of Committees were appointed:

Business Committee.—Dr. Norman Walker (chairman), Sir Francis Champneys, Dr. Macdonald, Dr. Mageunis, the President (*ex officio*).

Pharmacopoeia Committee.—The President (chairman), Dr. Caton, Dr. Hopkins, Dr. Matthew Hay, Dr. Norman Walker, Dr. Kidd, Sir John Moore, Sir Norman Moore, Dr. Russell Wells.

Finance Committee.—Sir Norman Moore (chairman), Mr. Waring, Sir James Hodsdon, Sir Arthur Chance, the President (*ex officio*).

Dental Committee.—The President (chairman), Mr. Bennett, Sir James Hodsdon, Sir Arthur Chance, Mr. Waring.

Dental Education and Examination Committee.—Sir James Hodsdon (chairman), Mr. Bennett, Mr. Waring, Dr. Adams, Sir E. Coey Biggar, Sir Arthur Chance, the President (*ex officio*).

Students' Registration Committee.—Sir Norman Moore (chairman), Sir Gilbert Barling, Mr. Littlejohn, Dr. Mackay, Dr. Kidd, Mr. Sinclair, the President (*ex officio*).

Executive Committee.—The President (*ex officio*), Sir Gilbert Barling, Dr. Macdonald, Sir Norman Moore, Mr. Waring, Sir James Hodsdon, Dr. Norman Walker, Sir Arthur Chance, Sir John Moore.

Penal Cases Committee.—The President (*ex officio*), Sir Francis Champneys, Sir Arthur Chance, Dr. Norman Walker, Dr. Macdonald.

FINANCE.

The report of the Finance Committee, on the motion of its Chairman, Sir NORMAN MOORE, seconded by Mr. WARING, was received and approved. The income of the General and Branch Councils for the year 1920 was £11,398 and the expenditure £9,438, leaving a surplus of £1,960 as compared with surpluses of £874 for the year 1919 and £341 for 1918. The assets of the General Council have fallen by £1,695; this is chiefly due to the transfer from the reserve of £1,772 to meet the cost of the inspection of examinations now taking place. The expenditure is not one which occurs annually, and therefore it has proved convenient to have a fund upon which to draw, thus obviating a large drain upon the resources of the Branches and rendering the comparison of accounts more easy. The receipts from the sale of the *Medical Register* and other publications of the Council amounted to £255 in 1920, this was almost double the amount received in each of the two preceding years. In this connection the Finance Committee reports that lists of new registrations each month are now supplied on payment to various bodies and firms to which they are of use, and it is hoped to add to the number of subscribers; the payments received amount to a considerable sum, and the increasing use made of the *Register*, as the book of reference for all those who require to know if persons are "legally qualified" or not, should lead to further sales.

INSURANCE PRACTITIONERS AND TUBERCULOSIS REPORTS.

THE Ministry of Health has issued the following Memorandum (48, P.), dated May, 1921, on the procedure suggested for adoption by insurance officers in regard to reports on insured patients furnished by practitioners under the National Insurance (Medical Benefits) Amendment Regulations (No. 2), 1921. Copies of the memorandum have been forwarded by the Ministry to county and county borough councils, metropolitan borough councils, and Tuberculosis Joint Committees in England for circulation among clinical tuberculosis officers.

Memorandum by the Ministry of Health.

1 Under the above-mentioned Regulations, which operate from the 1st day of May, 1921, insurance practitioners are required, as formerly under the Tuberculosis (Domiciliary Treatment in England) Order, 1916, which is superseded by the Regulations, to furnish in a prescribed form periodical reports upon each of their insured patients who is suffering from tuberculosis. The Regulations, of which a copy is enclosed, provide for the reports to be transmitted by the practitioner to the Regional Medical Officer appointed by the Minister in accordance with the provisions of the National Health Insurance (Medical Benefit) Regulations, 1920, for the district in which the practitioner carries on insurance practice, and the Regional Medical Officer will forward the reports received to the appropriate Tuberculosis Officer.

2 The Regulations also provide that in regard to each insured patient suffering from tuberculosis the first report is to be made when treatment is first required to be given by reason of tuberculosis, and that subsequent reports must be made at such reasonable intervals, not exceeding three months, as may be arranged between the practitioner and the Regional Medical Officer during the continuance of the treatment. It will presumably only be in exceptional circumstances that a shorter interval than three months will be considered necessary, and the Regional Medical Officer will not in any case, either when acknowledging receipt of the initial report upon a particular case from the practitioner or in subsequent correspondence, specify a shorter interval except at the desire of the Tuberculosis Officer concerned.

3 In order to avoid unnecessary correspondence it is considered desirable that reports upon a particular case subsequent to the first should be sent direct by the practitioner to the Tuberculosis Officer of the Dispensary serving the district in which the patient resides, and the Regional Medical Officer will on receipt of the initial report inform the practitioner to this effect. Similarly any communications in regard to such later reports should as far as possible pass direct between the Tuberculosis Officer and the practitioner (see paragraphs 4 (b) and 5).

4 The initial report should ordinarily be sent by the practitioner to the Regional Medical Officer on his own initiative, but cases may arise in which a practitioner fails to furnish an initial report upon a tuberculous patient. It is suggested that the adoption of the following procedure by Tuberculosis Officers will ensure, *inter alia*, that initial reports are obtained through the Regional Medical Officer in all cases, and will be convenient in other respects:

(a) In new cases of tuberculosis which come to the Tuberculosis Officer's notice, through the notifications made under the Tuberculosis Regulations or otherwise, the Tuberculosis Officer should in the first instance communicate by telephone or otherwise with the practitioner who notified the case and inquire whether he desires to consult the Tuberculosis Officer in regard to the form of treatment most suitable to the circumstances of the case, and (unless the Tuberculosis Officer already possesses information on the point) whether or not the patient is an insured person. In the case of an insured patient, the Tuberculosis Officer should, after an interval of a week, if in the meantime no report is received from the practitioner in attendance, bring the matter to the notice of the Regional Medical Officer, who will in accordance with instructions issued to him take the steps necessary to secure the submission of the report required.

(b) In cases of tuberculosis in which the initial report has been received by the Tuberculosis Officer from the Regional Medical Officer, the Tuberculosis Officer should, after an interval ordinarily of three months from receipt of the report, intimate to the practitioner that a further report is due. It may be found convenient for the Tuberculosis Officer to obtain from the Insurance Committee concerned copies of the form prescribed for such reports and to remind the practitioner that a report is due by sending him a copy of the form with the name and address of the patient inserted.

If the report is not promptly received by the Tuberculosis Officer he should communicate with the Regional Medical Officer in order that appropriate action may be taken by the latter.

(c) As regards tuberculous insured persons already under treatment by insurance practitioners on the 1st May, 1921, the Tuberculosis Officer should, when the next report has become due, proceed as in 4(b).

5. In cases where reports made under the Regulations, and received by the Tuberculosis Officer from the Regional Medical Officer or from the practitioner direct, are defective, it will be convenient if requests for amendment of such reports are sent by the Tuberculosis Officer direct to the practitioner concerned in the first instance. If, however, difficulty is then experienced in obtaining an amended report the Tuberculosis Officer should communicate the facts to the Regional Medical Officer stating the amendments desired, in order that the latter officer may take steps to have the necessary amendments effected.

6. Under the Regulations, a practitioner, in addition to furnishing periodical reports, is required to confer with the Tuberculosis Officer, at such times and in such circumstances as may be arranged between them, in regard to patients suffering from tuberculosis. It should be noted that it rests with Tuberculosis Officers to arrange direct with practitioners for such conferences upon particular cases of insured tuberculous patients.

Correspondence.

Dr. Macdonald's Mission to South Africa.

SIR,—Under the heading "Dr. Macdonald's Mission to South Africa," in your issue of March 12th, 1921 (SUPPLEMENT, p. 70), there are certain inaccuracies which require correction.

It would appear that Dr. Macdonald gave an account of the proposal to establish a Medical Association of South Africa to a Council meeting held on February 26th. Dr. Macdonald attended the meeting of delegates of the British Medical Association at the Durban Congress when this question was discussed. He states, quite correctly, that one object of the proposed new association was to obtain national expression, but he is reported to have continued in the following terms:

"A keen discussion took place, during which it appeared that the movers in the scheme proposed to form the new association into a trade union and register it as such. It seemed that in this matter they considered they would be hampered by the constitution of the British Medical Association, and that they were of opinion that the British Medical Association could not undertake collective bargaining."

Now, Sir, Dr. Macdonald has apparently entirely misunderstood the position taken up by the Witwatersrand Branch of the British Medical Association and the arguments used by the movers of the resolution of that Branch.

The possibility of forming a trade union was never contemplated or considered in the deliberations of the joint committee of the two medical associations appointed to draw up the draft constitution of the South African Medical Association. The suggestion that such a trade union should be registered is absurd in the face of the fact that there is no such body as a trade union in the legal sense in this country, and no means therefore by which it could be registered.

Again, there is no doubt in our minds that the British Medical Association can and does engage in collective bargaining. The point is that in this country the British Medical Association cannot, under its constitution, enforce any such bargain upon its members. That is the legal opinion we have obtained.

Finally, let us be quite plain upon the issues involved:

1. We want an association of a national character which will attract all members of the profession irrespective of race or politics.
2. We want to have the power, amongst others, to bind our members to conform to the decisions of the association, but
3. We do not want a trade union.

—We are, etc.,

RONALD P. MACKENZIE,
FRANCIS NAPIER,

Mover and Seconder of the Resolution
at the Durban Congress.

Johannesburg, April 27th.

Anaesthetists' Fees in Insurance Practice.

SIR,—The discussion that has recently taken place under this heading raises the important question of the payment of medical men for attendance on insured persons in hospital.

Is there any statement in the terms of service under the National Health Insurance Act that we are required to give only domiciliary and not institutional attendance?

The terms of service include:

Range of Treatment.—"The treatment which a practitioner is required to give to his patients comprises such treatment as is

of a kind which can, consistently with the best interests of the patient, be properly undertaken by a general practitioner of ordinary professional competence and skill."

Visiting.—"A practitioner is required to visit and treat a patient whose condition so requires at any place where the patient may at the time be within the district in which the practitioner has under these terms of service undertaken to visit patients."

So that, provided the attendance required is within the stated range, we may assume that the practitioner is required to give it whether the patient is in an institution or not, provided he is in the agreed district.

The competence of a general practitioner is not lessened by having to give attendance in an institution. We claim that the primary or cottage hospital is a general practitioner hospital, and that, given the advantages of an institution, we can there practise our profession more effectively and more easily than in the homes of our patients.

If it is worth our while to attend patients in their homes for the insurance fee that we get, surely it is a much better bargain for us for the same fee to attend those same patients in hospitals, where the time taken for visiting is less, where more than one patient can often be seen at the same visit, where a good deal of the work that we have to do ourselves in the home is done for us by the nurse, and where we can leave patients to be watched by trained attendants, that at home we might require to visit frequently for mere observation.

If institutional treatment is more effective patients are cured in a shorter time, and so require a less amount of attendance from the medical man.

In recent discussions as to paying wards in hospitals, Poor Law institutions, etc., the right of the general practitioner to follow his patient has always been advanced, as also has his demand to be allowed to take part in the work of the various communal clinics, so that we must be careful not to depreciate our competence to undertake such work, or we may find it difficult to sustain our claim.

It should be no more difficult to define general practitioner work in hospital than in domiciliary practice.

If the above stated views are accepted we shall give attendance in primary hospitals as part of our contract, and then the question arises as to the payment of the medical man who gives general practitioner attendance in hospital to a patient who is on the list of some other medical man in the district—should not that medical man be responsible for the payment? otherwise we may find practitioners sending patients into hospital and themselves receiving payment for work which others are doing. If such payment is to be made, the method (not the fees) adopted under the Insurance Act for payment for emergency treatment would seem convenient and fair.

Insured persons from other districts could be paid for as temporary residents.

Until we settle the question here raised we cannot deal satisfactorily with the rest of the problem of the payment of the medical staffs of voluntary hospitals.—I am, etc.,

CHAS. E. S. FLEMING.

Bradford-on-Avon, May 22nd.

SIR,—The Croydon Panel Committee resolved that Clause 2, paragraph 1, of the Distribution Scheme should run as follows:

"In cases in which the co operation of a second practitioner is required in the performance, under a general anaesthetic, of an operation within the scope of medical benefit, and where no provision would otherwise ordinarily be made for the administration of the anaesthetic, the following scale of fees," etc.

This wording, if adopted by other Committees, should quiet the fears of your previous correspondents.—I am, etc.,

G. GILBERT GENGE,

Hon. Secretary.

Croydon, May 21st.

Election of Panel Committees.

SIR,—The suggested schemes just issued by the Ministry of Health are but little improvement upon the originals.

The term of office of the Committee may be two years, or a number of the members are to be elected annually, the election in each case to be carried out by a special returning officer, who may not be an elector. This involves unnecessary expense, trouble, and labour.

The secretary of a Panel Committee is often a Panel practitioner, and hence may play no part in carrying out the election and can issue no notices, etc.

The election generally takes place at a general meeting at which topics of other interest are considered, and of which the honorary secretary gives notice, and the returning officer has to circularize all practitioners as well upon

the election—a double cost to be borne by the Panel Committee.

Surely a notice issued to practitioners by the secretary of the Panel Committee upon the election should suffice and be valid, and surely practitioners should be able to appoint their own representatives without having to pay for a returning officer, generally of the legal profession.

The Government negotiates with bodies elected under conditions far less stringent than those demanded by the Ministry of Health. Any method of election, provided it is carried out in good faith, should be allowed, and there is no necessity every year or two for the strict formalities of a parliamentary election. But the Ministry of Health loves red tape—I am, etc.,

SIDNEY CLARKE, M.D.,

Honorary Secretary Hertfordshire (Local) Medical,
St. Albans, May 15th. and Panel Committees.

National Health and the Practitioner.

SIR,—Appropos of your report of the discussion on "National health and the practitioner," in the SUPPLEMENT of May 14th, the question arises, How far are medical men generally content to leave advocacy in the hands of the "Reds"?

The discussion is opened by Dr. Buchan with claims and figures that would not deceive a schoolboy. But the humour of the situation emerges when, in quoting the enormous reduction in the death rate during the last forty years, he pushes for revolutionary changes in medical practice. If he does not get in quick enough with his whole-time public service and get every medico over thirty scrapped, there might be no death rate to worry about. He must hasten to draw blood from the retreating enemy ere he is beyond his reach.

Humour does not end with Dr. Buchan, however. Dr. Haslip, after criticizing Dr. Farquharson for a political platform speech, proceeds to deliver a typical harangue as addressed to an open-air meeting of the uninstructed. Communism out and out, of which the general practitioner is to bear the cost apparently. I do not know how far Dr. Haslip goes in his communism; most communists are discovered to have limits when cross-examined. Dr. Haslip talks airily about "the failure of the Insurance Act" as if it were an accepted fact. No statement could be farther from the truth. Defects there are which are remediable, but on the whole it has worked well, and certainly no whole-time service that is conceivable would give better results.—I am, etc.,

Gateshead, May 15th.

JOHN L. SPEIRS.

SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH.

SCHOLARSHIPS.

THE Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows:

1. AN ERNEST HART MEMORIAL SCHOLARSHIP, of the value of £200 per annum, for the study of some subject in the department of State Medicine.

2. THREE RESEARCH SCHOLARSHIPS, each of the value of £150 per annum, for research into some subject relating to the Causation, Prevention, or Treatment of Disease.

Each scholarship is tenable for one year, commencing on October 1st, 1921. A Scholar may be reappointed for not more than two additional terms.

The Conditions of the award of Scholarships are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C.2.

GRANTS.

The Council of the British Medical Association is also prepared to receive applications for Grants for the assistance of Research into the Causation, Treatment, or Prevention of Disease. Preference will be given, other things being equal, to members of the medical profession, and to applicants who propose as subjects of investigation problems directly related to practical medicine.

The Conditions of the award of Grants are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C.2.

Applications.

Applications for Scholarships and Grants for the year 1921-22 must be made not later than Saturday, June 25th, 1921, in the prescribed form, a copy of which will be supplied by the Medical Secretary on application.

Each application should be accompanied by testimonials, including a recommendation from the head of the laboratory, if any, in which the applicant proposes to work, setting out the fitness of the candidate to conduct such work, and the probable value of the work to be undertaken. This is not intended, however, to prevent applications for Grants in aid of work which need not be performed in a recognized laboratory.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES. COVENTRY.

THE Coventry Panel and Local Medical Committee met at Coventry on May 13th, Dr. W. H. Lowman presiding. The question of the amendment of the schemes governing the constitution of Panel Committees came under review, together with the suggestions of the Ministry as to amending the present schemes. It was decided to convene a general meeting of the Coventry electorate to place before them an amended scheme on which to hold the election, and not to proceed to the election on the current scheme. The variations from the present arrangements which are to be recommended to the electorate include the provision that one-third of the Committee shall be elected annually, and that voting shall be by postal vote.

The nursing scheme recently circulated by the industrial group of approved societies, which is understood to have been recommended by the Queen Victoria Jubilee Institute to its affiliated branches, was reviewed and severely criticized. Members took strong exception to the possibility of the services of nurses being called to a case by any third party in the form of an approved society representative; and the following resolution was unanimously adopted, and authorized to be sent to the Insurance Acts Committee of the British Medical Association and others:

That, in the opinion of this Committee, any nursing scheme which imposes a charge upon the funds of insured members of approved societies, or which renders insured persons liable to a charge, should be the subject of arrangements made to the satisfaction of the Minister of Health acting in conjunction with Panel and Insurance Committees; and that this Committee strongly protest against any scheme in which the matter of requisitioning the services of a nurse is not left to the judgement of the medical practitioner.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following notifications are announced by the Admiralty:—Surgeon Commanders: W. N. L. Cherry to the *Benbow*, on re-commissioning; R. W. G. Stewart to the *Emperor of India*, on re-commissioning; A. Woolcombe, to the *Glorious*, on becoming flagship, Surgeon Lieutenant Commander: H. E. Scargill to the *Fivid*, additional, for special service. Surgeon Lieutenant A. C. Esmonde to Haslar Hospital.

Surgeon Lieutenant Commanders promoted to the rank of Surgeon Commander: H. F. Briggs, A. G. Malcolm, H. C. Devay, H. Burns, O.B.E. Surgeon Lieutenants promoted to the rank of Surgeon Lieutenant Commanders: G. W. Woodhouse, H. B. Padwick, D.S.O.

ARMY MEDICAL SERVICE.

Lieut.-Colonel R. J. W. Mawhinny, C.B., from R.A.M.C., to be Colonel, December 25th, 1918, with pay and allowances from March 24th, 1921.

ROYAL ARMY MEDICAL CORPS.

Captain (temporary Major) A. S. Cane, D.S.O., O.B.E., retains his temporary rank whilst employed as D.A.D. of P. Temporary Captain (acting Major) H. G. Hobson, O.B.E., M.C., to be Captain, with seniority December 19th, 1918, and to retain his acting rank.

The following temporary Captains relinquish their commissions: (Acting Major) C. C. Chance, M.C., and is granted the rank of Major; H. Stanger, and retains the rank of Captain.

Lieutenant (temporary Captain) T. B. H. Tabuteau to be Captain.

DEFENCE FORCE.

ARMY MEDICAL SERVICE.

To be Assistant Directors of Medical Services: Temporary Colonels F. W. Higgs, C.B.E., J. G. Martin, T.D., D. Rorie, D.S.O., H. T. Samuel, D.S.O., E. A. Wraith, C.B.E., D.S.O. To be Deputy Assistant Directors of Medical Services: Temporary Captain S. S. Graves, D.S.O., M.C., temporary Captain O. Teichman, D.S.O., M.C., temporary Major F. W. Smeir, T.D.

R.A.M.C.—To be temporary Majors: C. V. Balstrode, D.S.O., T.D. To be temporary Captains: J. D. G. Stewart, H. Drummond, W. J. C. Watt. To be temporary Lieutenant: G. L. Lyon-Smith.

1st (East Anglian) Field Ambulance (D.F.).—To be temporary Major: W. S. Forbes, April 10th, 1921 (substituted for London Gazette notification, April 27th, 1921, appointing this officer as temporary Captain). To be temporary Captains: A. G. Atkinson, M.B.E., H. F. Gilmour.

2nd (East Anglian) Field Ambulance (D.F.).—To be temporary Captain: W. T. G. Boul.

1st (East Lancashire) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: T. B. Wolstenholme, O.B.E. To be temporary Captains: J. F. O'Grady, T. Hamilton.

1st (Highland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: A. S. K. Anderson. To be temporary Lieutenants: I. S. Thompson, J. I. Moir, G. Burnett, D. R. Macdonald.

2nd (Highland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: J. W. Tocher. To be temporary Major: W. F. T. Haultain. To be temporary Captain: H. J. Rae. To be temporary Lieutenant: H. J. Dawson.

3rd (Highland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: G. W. Miller, D.S.O., T.D. To be temporary Major: W. A. Robertson, M.C. To be temporary Captains: J. Kinnear, D. Roger, W. E. A. Buchanan.

1st (Home Counties) Field Ambulance (D.F.).—To be temporary Captain: E. A. Houchin.

2nd (Home Counties) Field Ambulance (D.F.).—To be temporary Captain: R. A. Freeman.

3rd (Home Counties) Field Ambulance (D.F.).—To be temporary Captain: Y. E. Negus.

1st (London) Field Ambulance (D.F.).—O. W. McSheehy, D.S.O., O.B.E. (Major R.A.M.C.) is granted the rank of temporary Lieut.-Colonel and is appointed to a field ambulance. To be temporary temporary Captains: A. B. Mount, A. L.

1st London Sanitary Section (D.F.).—To be temporary Captain: H. C. Sands.

2nd London Divisional Sanitary Section (D.F.).—To be temporary Captain: H. Brian-Pearson.

2nd London Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: H. G. Haynes. To be temporary Captains: M. Coughlan, W. Hassard. To be temporary Lieutenant: G. W. Almeyde.

3rd (London) Field Ambulance (D.F.).—To be temporary Lieutenant-Colonel: M. H. Allen. To be temporary Captain: L. J. G. Carre.

4th London Field Ambulance (D.F.).—To be temporary Captain: C. H. Welch.

5th London Field Ambulance (D.F.).—To be temporary Lieutenants: J. R. K. Flemming, H. W. Collins.

6th (London) Field Ambulance (D.F.).—To be temporary Captain: E. H. Bingley.

1st (Lowland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: E. S. Forde. To be temporary Major: E. P. Cathcart. To be temporary Captain: J. K. Rennie. To be temporary Lieutenants: A. H. Jacobs, N. M. D. Fox.

2nd (Lowland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: G. B. Fleming, M.B.E. To be temporary Major: J. R. C. Greenlees.

3rd (Lowland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: F. A. E. Crew. To be temporary Captains: J. A. L. London, C. G. Lambie. To be temporary Lieutenants: O. H. Wild, E. H. Ponder, R. K. S. Lim.

52nd (Lowland) Division Sanitary Section (D.F.).—To be temporary Captain: M. Wilson.

Field Ambulance (D.F.).—To be temporary Fisher, D.S.O. To be temporary Major: V. To be temporary Captains: D. Roberts, F. C. Fridham,

Field Ambulance (D.F.).—To be temporary Major: F. G. Hobson. To be temporary Captain: W. D. Gardner.

2nd (South Midland) Field Ambulance (D.F.).—To be temporary Major: Temporary Captain W. W. Newton. To be temporary Captain: Temporary Lieutenant N. C. Cooper.

3rd (South Midland) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: T. A. Green, D.S.O. To be temporary Major: D. S. A. O'Keefe. To be temporary Captains: A. D. Symons, J. C. Brasher. To be temporary Lieutenant: B. A. Astley-Weston.

3rd (Welsh) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: C. L. Isaac.

1st (Wessex) Field Ambulance (D.F.).—To be temporary Lieut.-Colonel: A. Cary. To be temporary Major: R. Ward.

49th (West Riding) Division Sanitary Section (D.F.).—To be temporary Captain: H. L. Robinson.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS.

- DONALD.—On April 23rd, at Nursing Home, Mansfield, to Dr. and Mrs. S. J. W. Donald, Herne House, Sutton-in-Ashfield, Notts—a son.
- FETHERSTON-DILKE.—On March 31st, at Leamington Spa, the wife of Beaumont A. Featherston-Dilke, M.B.E., M.B.Cantab., M.R.C.P., of the West African Medical Staff, Nigeria, of a son.

DEATHS.

- BARRETT.—On May 22nd, at Colwyn Bay, Walter Ernest, the beloved husband of Dorothy L. Barrett, after a long and painful illness.
- JEFFERIES.—On May 21st, at 104, Chorley New Road, Bolton, Horace Jefferies, M.R.C.S., L.S.A., in his 61st year.
- WEST.—On May 19th, 1921, at 48, St. George's Road, S.E.1, William Goldsborough West, M.D., M.R.C.S., L.R.C.P. (second son of the Rev. George West, of Horham Hall, Thaxted, Essex), aged 55 years. R.I.P. (French papers please copy.)

author ascribes to an intellectual defect, a lack of *sagacity* or ability to comprehend properly the part in relation to the whole and to discriminate out of a whole the appropriate, relevant, or significant detail. A *neurosis* is thus apparently to be regarded as a form of congenital intellectual deficiency. The *psychoneurotic* is deficient in *sagacity* as the feeble minded is in the capacity for *learning*. We should have imagined that there was quite sufficient evidence to show that the redintegrative reactions in the psychoneuroses were the result of the suppression of painful experiences rather than the expression of stupidity. Professor Hollingworth objects to the whole terminology and conceptions of the psychopathologist, and there is here, no doubt, a legitimate held for criticism, but he would scarcely seem to be in a position to dispute the basic conceptions which have been formulated as to the significance of neurotic symptoms. If he objects to the concept of the unconscious, he need only refer to the work of Schweb in his own country in which an objective and physiological conception of the psychoneuroses is developed, but this writer finds, as all psychopathologists have hitherto done, that these disorders have their origin in the instinctive rather than in the intellectual mental life.

The actual data upon which the author bases his hypothesis are by no means convincing. It is true that he finds many of his cases slightly subnormal in intellectual level, but these patients are obviously in no sense representative of the psychoneurotics found in civil life, and neither can they be regarded as characteristic of the mentality of the whole group of war neurotics. However this may be, 787 out of the 1,172 cases tabulated in his book are not neurotics at all, but are classified under the headings of mental deficiency, epilepsy, constitutional psychopathy, concussion, cerebro spinal meningitis, organic conditions, psychoses, and undiagnosed. While this study may have some value as a mere record of the mental level of a number of nervous cases, as a contribution to the psychology of psychoneurotic symptoms it is of but little significance.

STEDMAN'S MEDICAL DICTIONARY.

We have remarked before on the debt owed by English-speaking members of the medical profession to the United States for the many excellent medical dictionaries produced in that country, and for the speed with which revised editions are brought out. The sixth edition has now reached us of the *Practical Medical Dictionary*,⁴ by Dr. T. L. STEDMAN. It is only ten years since this work first appeared, and the favour with which it has been received is proved by the fact that a second edition was needed within eighteen months, and that since then a new edition has been called for every second year. The first edition was noticed at some length in our columns at the time. The general style and arrangement have been preserved, but the number of pages has had to be increased to keep pace with the ever-growing number of new words and altered meanings. With a lexicon of this size and scope the work of continuous revision and correction must be very heavy; the author speaks of it in his supplementary preface as a truly Sisyphean task, "one edition being no sooner published than the collection of new words and new uses of old words begins anew." So far as we have been able to test the new edition, this dictionary appears to maintain the accuracy and the clearness of definition which have made it so popular as a work of reference in medical libraries.

ELECTROTHERAPY IN UROLOGY.

Dr. COURTADE has collected into one volume, entitled *Notions pratiques d'électrothérapie*,⁵ much that it is useful to know on the subject of electrotherapy applied to urological conditions. There is perhaps no branch of surgery in which electrotherapy holds a more important position than in the surgery of the genito-urinary system, and Dr. Courtaude's book should certainly be of great utility. To write a work of this kind requires special

qualifications such as few men possess. It needs a greater knowledge of electrical instruments than most medical men have, and at the same time demands considerable experience in urology. Dr. Courtaude appears to be eminently fitted for the task which he has undertaken. The book is divided into two parts. In the first part are described the different varieties of an electrical current, the means by which they may be generated, and their action on tissue in general. The second part is devoted to a consideration of the various lesions of the genito-urinary tract that are amenable to electrical treatment. Advice is given as to the best form of such treatment for the various lesions described, and, where possible, the reasons are supplied why a particular form of current is better than another. Although the second portion of Dr. Courtaude's book does not contain a great deal of new material, certain minor changes are effected which are doubtless improvements. The work should prove interesting to urologists and electrotherapists alike.

NOTES ON BOOKS.

IN his *Letters to a Nurse*⁶ "A Midland Doctor" (who from the preface we may suppose to be Dr. F. G. Layton) provides some instruction for probationers on the nature and origin of disease, and on the duties of nurses to patients. The instruction is sound and on the right lines. But the author's main purpose appears to be to encourage the probationer with his fatherly—or avuncular—advice to endure the drudgery and hardships of her early training, and at the same time to rebel against certain abuses, such as bad feeding, excessive hours of duty, and the degrading hospital routine. Incidentally the letters are used as a means of attacking many priests and some matrons and ward sisters. The matron or sister who is a matinet may well have attention directed by a doctor to her shortcomings, but the priest is in a different position; there seems to be no good reason why the Midland Doctor should use his letters to nurses as a medium for an attack on another profession; especially when, in doing so, he may hurt the religious susceptibilities of some young women. It would be wiser to address a separate series of letters to a priest. By using Lord Chesterfield's method, and addressing letters to his niece, the author is able to allow himself much latitude in style. But his illustrious predecessor would hardly have written "the very most difficult"; "conscious 'doing good' is the very most priggish of vices"; "we know different, don't we?" or "I shall go and find out what is the reason why." The vigour of his sentiments may be gathered from his denunciatory remarks on charity and the voluntary system; his sense of humour by his quotation of the message from a lady patient, "Will you please call to-morrow as little girl is ill at your convenience and oblige."

⁶ *Letters to a Nurse* By a Midland Doctor. London: J. Bale, Sons and Danielsson 1921. (Fcap 8vo, pp 99 5s net.)

APPLIANCES AND PREPARATIONS.

A Draining Rack.

THE "Rycott" draining rack, of which we have received a sample, is a simple wooden device for draining glass tumblers, measure glasses, and cups. Articles after being washed can be placed between the slits of the pegs and left to dry, as shown in the illustration. The rack is made either to stand on the table or to fix on the back of a sink; single pegs are also made to

screw on the side of the plate rack or the draining board. The rack, or pegs, should prove a convenience in laboratories, dispensaries, and photographic dark rooms. The price of the rack is 2s., and single pegs are 3d. each. They may be obtained from Messrs. Maw, Son and Sons, or from the makers, Messrs. Rycott and Dixon, 115, Balham Hill, London, S.W.12.

THE Czecho-Slovak Red Cross has organized forty country colonies for a total of 10,000 children and will shortly open a children's hospital.

⁴ *A Practical Medical Dictionary*. By Thomas Lathrop Stedman, A.M., M.D. Sixth revised edition. London: Baillière, Tindall, and Cox. 1921. (Roy. 8vo, pp. 1160; illustrated. 42s. net.)

⁵ *Notions Pratiques d'Électrothérapie appliquée à l'Urologie*. By Dr. D. Courtaude. Second edition. Paris: E. le François. 1921. (Roy. 8vo, pp. 244; 37 figures. Fr. 18; post free, Fr. 19 50s.)

THE ORGANIZATION OF SCHOOL OPHTHALMIC WORK.

BY

N. BISHOP HARMAN, F.R.C.S.

ALL the mental and physical powers of a child are brought into play in school life. Defect in one of these powers will act as a handicap. The child with a defect will not be able to do so well in work or in play as the better equipped child. Some defects are more than handicaps; they may become irritants and react on the general welfare of the child. A child with some degree of deafness will fail to hear low tones; the failure is a loss. The sensitive child may be aware of the loss and worried by it, but the effort to hear will involve no ill effect. A child with defective sight will fail to see clearly; the loss may cause worry, but more serious is the likelihood that the effort to see will cause a strain that may further damage the eyes and even disturb the balance of the nervous system. The ill effects of defective sight are progressive and cumulative. If we leave out of account the dominant part played by sight in the development of human mental and physical powers, still the significance of defective sight is such that no effort is lost which seeks to diminish or ameliorate the defect.

The Discovery of the Defect.

Parents are so accustomed to their children and their ways that they can rarely be relied upon to notice any but the most obvious defects. The school becomes the testing ground of the physical qualities of the child even as it is of its mental capacity. Mentality and physique are so closely involved that teachers need as much training in the observance of physical characters as they receive in scholastic and mental culture. It is desirable that teachers should receive in a course of school hygiene instruction in the recognition of simple eye defects, such as the recognition and dangers of sore eyes, the seriousness of squint and the urgency of its early and continuous treatment, and in the methods of measuring and recording visual acuity. An educated and observant teacher is the first line of defence in protecting the child from the strain arising out of its inherent disabilities. Every teacher ought to know the meaning of a vision test-type, and be able to discover the value of a child's sight by the use of that test and to record it. Many teachers have learnt this during school medical inspection; not a few instances have come under notice of the value of this knowledge; one may be cited:

During the visit to a school for a purpose unconnected with inspection a school doctor was asked to look at a boy, for his teacher had noticed that he could not see properly; the previous term's vision had been 6/6; when he was tested by his teacher that week his vision was only 6/60; examination of the boy showed that he was suffering from acute optic neuritis.

The test-types should be a familiar object in the school, and it should be of such a kind that it cannot be memorized however frequently seen. For this reason experience shows the advantage for the school use of the E-sign card, in which there is only one sign for each grade mounted on a turntable that may be moved at will. The test cannot be learned; it requires no knowledge of letters; the response is simply the movement of the hand to correspond with the position of the pointers of the sign.

There appears to be no reason why an initial test of vision should not be done by the teachers; it would give them a knowledge of their charges that they would not otherwise obtain, and it would accentuate their interest in the conservation of child sight. These preliminary findings would be at the service of the school medical inspector at his visitation. Observant teachers are most of all necessary in infant departments. At present infants under the age of 7 years attending school do not have their eyes examined; yet I have shown by a routine examination by objective methods of the eyes of all the infants attending a large good class elementary school to the number of 368 that 36.9 per cent. had defects of the eyes and no less than 16 per cent. considerable defect eyes (Trans. Ophthal. Soc. U.K., 1919, p. 89). These infants, fit and unfit, do the same work; and it must be remembered that what we adults think easy infantile tasks are in reality very laborious and fatiguing to infants. It is not practical to attempt to distinguish these defects by a vision test with test-types. The test could only be made satisfactorily by the routine objective examination of the

eyes of each entrant by the medical officers, just as though the child had been referred to the clinic for defective vision. If such a course could be adopted it would be possible to indicate the normal eyed (or rather average eyed) children, those with slight defect of vision, and those with more serious defects, and to suggest arrangements for the work of these grades of children according to their fitness. It is likely that an educational arrangement based on a real knowledge of the condition of the children's eyes and the correction of the gross defects at an early age would tend to check the onset of much of the myopia we find developing in later years. Such a proposition may be deemed impracticable in the present state of public finance. The burden of detecting the serious defects of infants' eyes, therefore, rests with the teachers. Infants who squint, even if only temporarily, whose eyes get tired, red, or irritable after work, or who fail to see marks on the blackboard or the details of wall pictures, should be noted and referred to the school medical officer. Similarly children who appear dull or stupid in general class lessons should be referred for examination, for it has been shown that many "stupid" children are stupid from inability to see. These signs of eye-strain should equally be noted by the teachers in other departments and reported.

The Measure of the Work to be Done.

The data given above, obtained by the objective examination of the eyes of infants at a good class school, show that 16 per cent. had serious defects that needed medical attention. Certain of the children with less serious defects will also need attention, let us say these will bring the total to 20 per cent. In London, with an average roll of 725,000 children, the average number of entrants in any year is 63,000, so that the minimum number of children requiring attention each year would be 12,600. To this must be added the number likely to require re-examination, who are about one-fourth of that number for any one child-year, or, let us say, for the several years of school life, a number equal to the entrants examined, making a total of 25,000 examinations each year. London school population numbers about one-seventh of that for England and Wales, so that the grand total on a low estimate will be about 176,400 for each year. The actual numbers of children attending London school clinics as fresh cases during the years 1912 to 1920 inclusive were: 16,670, 21,464, 25,952, 25,286, 26,905, 27,062, 26,200, 28,011, 29,837, making an average for the nine years of 25,400.

Treatment of Defects.

It should be premised that any arrangement made for the treatment of eye defects in children should be in close relation with the schools, so that the results of the treatment may be available for the guidance of the school authorities. Many of the defects found are not completely susceptible to full correction, and the remaining defect may be one that requires special arrangements for the satisfactory education of the child. If the arrangements for treatment are not made with this close relation to the work of the school, a large part of the benefit of the treatment may be lost. When school clinics are provided by the education authorities there is no difficulty in making the desirable connexion; and it does not appear impossible to secure a like conveyance of the necessary information when the child is treated independently of these arrangements by the private practitioner of the parents' choice.

Arrangements for School Clinics.

These will differ in town and country. In towns where there are large aggregations of children it is easiest and best to plan definite clinics in suitable places which may serve a number of schools. In small towns satisfactory schemes are now in working whereby the local practitioner competent in ophthalmic work receives the children who are to be examined in his own house; the arrangement is economical, since it avoids the expense of setting up an independent clinic for a relatively small number of children. In the country these plans will be unsuitable, as schools may be far apart and the numbers in each may be small, so that a clinic could not be economically arranged to serve a given area. In the country, therefore, treatment is best carried out in the school premises by doctors who attend the schools in rotation on a plan prepared by the chief school medical officer. The apparatus needed by the doctor can be readily transported from place to place. The provision of a room suitable for ophthalmoscopic examination is not a matter of difficulty; any room that can be darkened and in which a suitable lamp can be provided will meet the need. Where electric light is in use a focus lamp appropriate for the particular current of the district,

with a length of flexible wire, is all that is needed; where gas is used the incandescent mantle provides a most satisfactory source of light, provided the bracket to which it is attached is placed low enough. Where there is no fixed source of light supply illumination can be best provided by a portable acetene lamp, of which there are many good patterns on the market. In towns, clinics will be arranged either on hospital premises, if these are conveniently situated, or at independent centres where these facilities are absent.

About 2 per cent. of children in the schools suffer from blepharitis and conjunctivitis. In many of these the need is for regular and efficient cleansing. In town areas this is best met by the establishment of "minor ailment centres," where, under the control of a medical officer, there is a staff of nurses who give daily attention to the eyes. It is desirable that where these centres are established they should be definitely linked up with the centres where the more detailed investigation of defects is carried out. Some of these cases of sore eyes are aggravated or caused by defects of refraction, and unless these are recognized and corrected there is no real likelihood of the surface irritation being checked. In country districts the care of such eyes can be best met, in the absence of any provision of school nurses, by arrangement with local nursing associations, so that nurses could be detailed off to schools at definite hours each day to undertake the cleansing of children with affected eyes, and the application of the treatment ordered by the visiting doctor.

Following up.

Examination of school clinic papers shows that even where there are satisfactory arrangements for the following up of children under medical treatment, the treatment or a continuity of treatment is often neglected. If this be so where there are efficient arrangements, how much more must be the loss where these arrangements do not exist or are elementary. It is desirable that some arrangement should be instituted whereby cases that need regular observation at stated intervals may be marked and reported to the school medical officer, so that the continuity of treatment and observation can be secured even when the child is removed from one area to another.

Provision and Repair of Spectacles.

In towns where clinics are established arrangements should be made whereby an optician attends at the clinic to fit spectacle frames to the children. This plan has many advantages over the plan of sending the children to the optician. When the former plan is adopted there is personal communication between doctor and optician, corrections and adjustment of frames are expedited, and, further, the time of the parents is saved materially. In country districts where the numbers are few the selection of frames should be done by the medical officer himself. He should be supplied with a set of half a dozen standard frames with which he can ascertain the proper fitting for each child, and to the form of prescription he should add the number or description of the chosen frame.

Some difficulty arises in the provision and repair of glasses owing to inability of parents to pay at the time of ordering the glasses. It does not seem desirable that these should be provided free of cost to the parents. When this is done there is a tendency to lack of care in their use, but when they are paid for by the parents much more care is noticed. If the parents of children who are found to have eyes that will need the regular use of glasses during school life could be invited to join a provident scheme into which they could pay regularly small sums to meet the cost of glasses and then repair, the difficulty would be met. Great saving of time would be effected through such a scheme, and particularly if local opticians came into it. At present children who need glasses badly are often without them for long intervals while funds are being raised and repairs made in distant workshops. In country districts a postal service for the supply and repair of glasses will be needed.

The care of spectacles may be materially advanced by a routine parade of all children wearing them, at stated intervals. It should be a duty of the head teacher to supervise the parade, and it would be advantageous if one of the teachers who had some mechanical aptitude were to undertake those small adjustments of bent, tight, or loose frames which add so much to the comfort of the wearers. This plan has been adopted in some large schools with excellent results.

Staff.

There will need to be variations in arrangement according to the type of district in which the work has to be done.

Identical arrangements will not fit town and country. In general it may be said that there are advantages in separating the work of school medical inspection from the treatment of children found to be defective.

(1) The assurance provided by the independence of the two officers provides against objections by parents who resent the allegation that there is a defect in their child, it gives a certainty to the finding that is conformable to that which we demand for our own children and indeed for our own persons. (2) Medical inspection involves a sound all round knowledge of children's physique, and it is not to be expected that a medical inspector with this full general knowledge will be also equally competent to deal with a number of specialities involved in the treatment of defects. (3) In the case of eye defects there are additional advantages to the community as a whole in arranging that the treatment of the defect should be spread over as wide a personnel as possible. At the present time there are not a sufficient number of practitioners with an expert knowledge of eye work to meet the growing demand. The equipment of an education medical staff to do the work for children is a practical proposition, but if this work be done by practitioners whose sole duty is educational, the services of these practitioners will not be available for the service of the community at large. It would appear, therefore, desirable that the treatment of eye defects should be carried out by private practitioners who give evidence of a competent knowledge of the work and will devote a definite part of their time to it. Such an arrangement would foster the supply of a rapidly increasing number of capable practitioners who would have a knowledge of the particular difficulties and dangers of eye defects in industry by their daily contact with the adult population, and therefore be the better able to advise on the education of the children and indicate that line of training which would best fit them for a lifework in view of the defects which may be present.

Since the work of a school eye clinic is so largely refraction work, the one test of competency for the practitioner in these departments is the mastery of the retinoscope and ophthalmoscope. The practitioner must have such a mastery of retinoscopy as will enable him both to work out every detail of the refraction with the mirror and to judge from his results what are the most appropriate glasses to order in any given case. He must be able to make his observations with reasonable speed, for the examination is tiring to children. Subjective tests are of little or no value for children and should serve only as a record of visual acuity under certain conditions.

The appointing authority cannot itself test the competency of candidates for the work, but it can and should require evidence of recent and sufficient work in the ophthalmic department of a teaching hospital or of private work over a sufficient period.

It is desirable that country school circuits and independent town clinics should be linked up with some central clinic under the charge of an experienced ophthalmic surgeon for the purpose of consultation or reference for special examination of difficult cases. Where a school clinic is established on the premises of an existing hospital special arrangements for these purposes are unnecessary, as they are made by the hospital staff. In other clinics there may be no such arrangement for consultation, so that the practitioner in charge of the clinic loses necessary assistance, and the best line of treatment for the children cannot always be secured. The establishment of such central clinics at existing hospitals would have an advantage in facilitating inpatient treatment and operation where such were needed. The officer of the local clinics should be at liberty to refer any case of difficulty for consultation, and should be specially invited to refer those cases where visual defect cannot be satisfactorily corrected and where no certain cause explains the failure, serious defects likely to handicap the child's education, cases where special educational methods appear necessary, and cases requiring extended treatment and operation.

Arrangements for Special Treatment.

A small percentage of the children suffer from disease of the eyes which are of a chronic order and connected with some general disability or defect in hygiene, such as chronic conjunctivitis, blepharitis, relapsing ulcer of the cornea, and syphilitic and tuberculous inflammations of the eyes. The danger to the eyes which these diseases present is such that treatment to be adequate must be so organized as to be immediate and continuous and therefore institutional. Treatment in clinics and out-patient departments of hospitals does not meet the need. The hygienic conditions of the child cannot be touched by such

measures. Further, unless the child is under complete control during the treatment, intermissions are likely to occur, and in just those cases where the danger is greatest. Arrangements should be made for the immediate report of such cases to the consultative clinic, the officer of which should be able to recommend the admission of the child to a suitable institution where the treatment may be carried out.

One of the difficulties in carrying through continuous treatment of this sort for a necessary period lies in the intervention of capricious parents, who cannot be brought to understand the seriousness of the conditions. It is worth considering whether this difficulty might not be met by the routine reporting of these cases as they arise to the local magistrates to whom fall the decision in school cases, so that their assent to treatment for a specific period might be obtained in advance. If the parent does not enter into some engagement, or the retention of the child be not obtained by other means, the success of the treatment may be prevented by the untimely withdrawal of the child, so that the heavy expenditure is wasted, the damaging effects of the disease are not prevented, and a permanent disability may follow.

Children with Serious Defect of Vision.

There are a number of children, averaging about 2 per 1,000 of the school population, whose vision is too bad for them to take advantage of the ordinary curriculum. Special arrangements are made for their education under the provisions of the Education Act of 1893. Difficulties arise in these cases on three counts: (1) The insufficiency of the provision for their education, (2) the occasional objection of parents, (3) the lack of general knowledge on the part of medical practitioners of the nature and reason for special provision for these children.

(1) The number of schools for the blind in the country appears sufficient. But despite the sufficiency there are found even today cases of young people who are blind within the meaning of the Act, and have been so for many years, and yet whose education has been "attempted" in ordinary schools. Cases such as these indicate a defect in the arrangements for reporting the findings of medical examinations and treatment, and point to the necessity for effective consultation arrangements as indicated above. It is imperative that these children should be provided with satisfactory educational treatment at the earliest possible age. Delay means a serious and irrecoverable loss to the child, and a far more expensive and prolonged training after school years to put them in the way of a satisfactory occupation. The provision for children with less serious defects of vision is less ample. It is being met in the towns where the numbers make it possible to provide special accommodation. This is best provided by the formation of small classes—"myope classes"—in the ordinary elementary schools, so that the children may remain associated with the normal children for part of their curriculum. There is a distinct disadvantage in providing for them in blind schools or in other independent centres, for segregation is likely to cause them to be thought more nearly akin to blind children than to the sighted, and therefore to handicap their start in life. In villages the needs of these short-sighted children may best be met by allowing them to remain in the ordinary schools, provided the teachers are informed of the nature of the defect, and of the prohibition of reading and writing except by methods in use in the myope classes.

(2) Parents who cannot be persuaded of the seriousness of the defects of their children's eyes sometimes evade the acceptance of proper provision by transferring them to private schools, where the nature of the defect may be unknown and unprovided for. Later, when the seriousness of the defect is realized, the children are once more referred to the education authority, and often at a date too late effectively to meet the needs of the children.

(3) Occasionally difficulties arise from a lack of knowledge of the meaning of educational blindness on the part of medical practitioners, so that a conflict of opinion as to the proper training of a defective child arises between the school doctor and the private practitioner. The more widespread the association of those engaged in these two branches of medical work the less will be difficulties of this sort; hence the advantage of associating as many private practitioners as possible with school medical treatment.

The Influence of School Medical Work on the General Community.

School work should not be considered in relation only to education as carried on in the schools. It is true that the primary object of the work is to prevent eye-strain, the aggravation of eye defects, and to remove a handicap that would diminish the value of education to the child. But there are other values. The lessons that are learned in school life are a preparation for the wider life of the community. And in some degree the inculcation of a sound system of treatment of eye defects of the school children will react upon the whole community. There is much

industrial inefficiency caused by ignorance and negligence of eye defects; when the knowledge of the necessity and possibility of the correction of these defects is widespread the gain will be great. Parents are learning this lesson through the work done by the school medical service, and a new generation of parents will have learned the lesson by practical experience.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held on May 18th at the offices of the Society, 11, Chandos Street, Cavendish Square, with Sir ALFRED PEARCE GOULD, President, in the chair.

The following report for 1920 was adopted:

Report for 1920.

Since the last report 11 new members have been elected and 6 have been lost owing to death and resignation. The Society consists at the present time of one honorary, 163 life and 137 ordinary members, making a total of 301. The annual subscription for a member who at the time of his election is under 40 years of age, is two guineas, if over 40 but under 50 three guineas, and if over 50 four guineas. There are special terms for life subscription.

The invested capital now stands at £144,250. By the By-laws only the income may be used for the payments granted for the relief of the widows and orphans eligible to receive grants. All life subscriptions and legacies are funded. The income from investments amounted to £4,682 5s. 2d., £373 2s. 1d. was received from subscriptions and donations, making a total income of £5,055 7s. 3d.; the working expenses were £299 7s. 6d. During the year two widows came upon the funds and three died. The sum of £4,584 was distributed among the annuitants of the charity. On December 31st there were fifty-two widows and six orphans in receipt of grants.

The Society, which is one of the richest of its kind in the United Kingdom, was founded in 1788, and incorporated by Royal Charter in 1864. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. Should a member remove anywhere outside the radius, even beyond the British Isles, he nevertheless remains a member of the Society, provided he has conformed to the By-laws. Relief is granted to the necessitous widows and orphans of deceased members of three years' standing and of life members.

At the present time the widow of such member who has an income of not more than a hundred pounds a year receives a grant, voted each half-year by the Court of Directors, at an average rate of £50 per annum, paid half-yearly in advance, and each orphan, up to the age of 16, receives a grant of £43 per annum. An orphan, on attaining the age of 16, by the By-laws of the Society ceases to be eligible to receive grants from the ordinary funds of the Society. There are, however, two special funds from which the Court of Directors can make grants to orphans after the age of 16, and special grants from £25 to £10 are made to widows.

The acting Treasurer drew attention to the fact that the working expenses of the charity were about 5 per cent. of the total income, which he considered most satisfactory.

A cordial vote of thanks was passed to the editors of the various medical journals for their courtesy in publishing notices of the Society from time to time.

Further particulars may be obtained on application to the Secretary. The next election of members will be on July 6th, 1921.

THE last quarterly return of the Registrar-General shows that 129,263 deaths were registered in England and Wales during the three months ended March 31st, 1921. This corresponds to an annual rate of 13.9 per 1,000 total population in 1920; it is the lowest rate recorded in any first quarter since the establishment of civil registration. Influenza was stated to be either a primary or a contributory cause of death in 3,235, or 2.5 per cent. of the total deaths registered last quarter. Of the 209,657 births, 9,505 were illegitimate. Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 101 per 1,000, being 17 per 1,000 below the average in the ten preceding first quarters.

FROM August, 1919, to March, 1921, 66 persons received prophylactic treatment for rabies at the Utrecht serological institute, 19 were treated in 1919, 39 in 1920, and 8 in 1921; the disease did not develop in any case. During the same period the animals in Holland attacked by rabies consisted of 1 horse, 4 cows, 41 dogs, and 1 cat. The cases all occurred exclusively in the four provinces of Groningen, Drenthe, Overijssel, and Gelderland.

British Medical Journal.

SATURDAY, MAY 28th, 1921.

PRE-NATAL DEATH.

THE third Sir John Struthers Lecture, which was delivered before the Royal College of Surgeons of Edinburgh on December 17th, 1920, has recently become available in print. The lecture was by the Professor of Anatomy in the University of Edinburgh, and was worthy of Professor Arthur Robinson's high reputation. The subject was pre-natal death, a matter about which not a little has been written in recent years, but the pre-natal death referred to was not that commonly meant and the term was used in a sense that differed widely from its accepted obstetrical employment.

By pre-natal death Professor Robinson means a sort of normal or necessary extinction of life due to the fusion of certain gametes (ova and spermatozoa) which, though in themselves quite healthy, yet by their union produce zygotes which have either no vitality to carry them further or only sufficient to take them a short distance or in a tattered condition along the path of ante-natal life. The zygote or impregnated ovum resulting from the meeting of certain ova and spermatozoa which from the point of view of persistent vitality must be called germinally incompetent or incompitable, is a weakling or a failure, and its failure is followed by an abortion which Professor Robinson calls "normal"—using the word "normal," however, in a rather special sense. With some other ovum such a sperm might give a living and a lively zygote, and similarly some other sperm might prove competent enough with the defaulting ovum, there is, in other words, an incompatibility at the moment of impregnation, the destined ovum is not met by the delegated spermatozoon, and so the zygote falls or can only stagger for a few paces along life's highway. To apply Augustine of Hippo's old phrase in a new fashion, the zygote comes into being carrying with him his own mortality (*circumferens mortalitatem suam*).

In coming to this conclusion that in a certain percentage of all germinal conjunctions there is this incompatibility with resulting mortality, Professor Robinson has been influenced by a series of observations he has made upon horses and mares (Clydesdales and thoroughbreds) and upon ferrets. By finding the ovum extinction rate and comparing it with the actual birth rate in these animals, he reaches what is termed the "pre-natal death rate." In the Clydesdales it varied from 46 to 50 per cent and in the thoroughbreds from 52 to 62 per cent, in the ferrets it was not more than 39 per cent and was most likely about 35 per cent. A pre-natal death rate (as above defined) is not peculiar to horses and ferrets, but occurs in other animals, amongst which swine, rabbits, guinea pigs, and Dasyurus (among the marsupials) are mentioned, as are likewise birds. Professor Robinson, therefore, asks himself the question, Why not also in the human subject? It should be mentioned that he took great care to avoid the intrusion of certain obvious fallacies, the parent animals were healthy, their environment was as usual, the

food was not altered, and there was no evidence that there was excessive use of the male. Neither could the pre-natal deaths be due to the "internal environment," the immediate surroundings in the genital organs, for dead and normally developing ova and young zygotes were found in the same passages, indeed, in the ferrets a dead zygote or a degenerate zygote was frequently situated between two normal zygotes. Professor Robinson is therefore justified in asking, 'Why not also in the human subject?' If this question be answered in the affirmative, we have to ask whether any change for the better in the surroundings of the expectant mother or in her health can increase the birth rate?

At this point great care must be taken to make sure that like things shall not be compared with unlike. Professor Robinson's 'inevitable pre-natal death' (although even here the word "inevitable" is scarcely permissible) is not to be confused with the avoidable stillbirth due to the use of high forceps when Caesarean section or the induction of premature labour ought to have been employed. Neither is it within the same category as abortion due to parental syphilis and preventable by the use of the salvarsan substitutes and mercury. It is possible to agree with Professor Robinson that some sterility is "normal" and unavoidable and that some pre-natal death is also "normal" or usual, and under ordinary circumstances cannot be avoided, without assenting to the "better dead" argument that we shall abandon all efforts to save ante-natal lives and to prevent sterility. The lecturer was careful to point out near the close of his most interesting address that he was not then concerned with the remaining and avoidable part of pre-natal mortality, but a special word of caution is needed in respect of Professor Robinson's conclusion that the condition of the uterine mucous membrane associated with normal abortions is not degenerative or diseased, but normal, and that treatment of it is not only unnecessary, but may probably be detrimental. It can only be after a careful process of exclusion that the diagnosis of a "normal" abortion can be made, and until that has been reached it would be unwise to rule out uterine curettage, which has often been followed by the birth of a full time child after one or even more abortions. Of course other means of treatment are not to be neglected.

Professor Robinson frankly admits that the human "normal pre-natal death rate" cannot at present be fixed, but he thinks that about half of it may be regarded as due to causes which, in a sense, are unavoidable, and therefore as not remediable by any treatment, local or general, of the mothers. He does not, however, make it plain that the type of pre-natal death to which he refers occurs possibly, if not probably, very early in ante-natal time, soon after, if not actually before, the date of the first missed menstrual period. His "normal" abortions, therefore, may be amongst those which, by their early incidence, escape the statistician and do not come under the treatment of the obstetrician. Professor Robinson's observations and conclusions do not, in fact, afford the obstetrician any excuse for relaxing his efforts to prevent miscarriages or for abandoning his efforts to save ante-natal lives. There is, however, the necessity, in forecasting the probable percentage of ante-natal lives which are capable of being saved by hygiene and treatment of expectant mothers, to make allowance for the pre-natal mortality which, in the present state of our knowledge and of our therapeutic means, is fitly to be described as inevitable. There are still many lives which fall to the child welfare physician to save, and the time is not yet

¹ Edinburgh Medical Journal, March and April, 1921, pp. 137-151, 209-231.

when, with all these safely carried on to birth, there shall remain no others except the zygotes inevitably foredoomed to extinction. Even in respect of these last it has yet to be shown that good hygiene among the parents, spread over several generations, may not diminish the number of the failures.

THE TYPHOID CARRIER.

THE typhoid carrier problem, about which so much has been written, is brought once again before us by Dr. William Travis Howard, jun., in a valuable study of the history of enteric fever in Baltimore during the last seventy years.¹ We may first refer to some of the more general features of his paper. Although the mortality attributed to this disease at Baltimore is still greatly in excess of that observed in English urban aggregates (the rate in 1919, corrected for non-residents, was 6.28 per 100,000, which may be compared with 1.4 for London, 1.5 for county boroughs, 1.6 for other urban districts, and 1.5 for rural districts), it has declined greatly in the last fifty years, having been nearly 100 per 100,000 in 1870 and over 70 as recently as 1890. Down to the year 1881 opportunities for the pollution of the water supply were abundant, but by that date great improvements had been effected, and, with the exception of a few years following the incorporation of new districts into the city, the typhoid curve descended for twenty years. After 1901 fresh pollutions of the water became abundant and the curve tended to rise until, after chlorination of the supply in 1911, a sharp descent began.

During the whole period between 1851 and 1894 conditions were very favourable for the pollution of milk. Much was obtained from cows kept in the city in circumstances appropriate for contamination by actual sufferers from typhoid or "carriers," while the milk was heavily watered from polluted wells and springs. After this period matters improved. The urban cow was to a great extent driven out, and the municipal authorities gave effect to the advice of their medical officers. A revolution in the control of milk supply followed the enforcement of ordinances in 1908 and 1912, the Health Department acquiring control of dairy farms outside the city. Yet, as late as 1917, nearly 8 per cent. of the reported cases were traced to milk. Dr. Howard remarks that unless milk bottles are uniformly sterilized as a matter of routine, bottled milk may be, during the prevalence of typhoid, more dangerous than milk served from the old-fashioned churn. "When milk is sold from the churn or can, the purchaser receives it in his own container, and the dairy takes nothing infected away from the householder."

The Baltimore authorities seem to deal drastically with "carriers"—in fact, to "apprehend" them. Whether the causal nexus established between the alleged carrier and the outbreak would usually satisfy Dr. Hamer is, perhaps, open to doubt. We will quote one of Dr. Howard's examples. It is that of a family in which, during a period of seventeen years, four outbreaks of typhoid in three generations had occurred. "The grandmother had contracted the disease seventeen years before; the next year her two sons, her son-in-law and daughter and an unmarried daughter, all living in the same house with her, developed typhoid fever. In June, 1916, this woman's grandchild, aged 7 years, who lived in her house, developed the disease. On January 2nd, 1917, a second grandchild, a sister of the first, was reported as a case of

typhoid fever. The whole family was cultured on January 8th, 1917, and the grandmother, the unmarried aunt, and the child who had had typhoid fever in June of the previous year, were all three found to be carriers."

The sequence is impressive, but some of Dr. Howard's arguments are not quite convincing. He instances the case of a coloured cook found "to be a carrier responsible for 9 cases of typhoid fever among college girls, and who appeared to be quite frank when submitted to the closest interrogation was unable to recall a febrile illness suggestive of ordinary clinical typhoid fever. She described, however, very clearly the symptoms of an attack of acute cholecystitis which she had had about a year before. . . . Had she not by chance transferred typhoid infection to a number of college girls at the same time, she would probably not have been apprehended. Upon such chances as these the transmission of this disease and the recognition of its mode often depend. None of this woman's personal associates gave a history of frank typhoid fever either before or after her attack of cholecystitis. . . . A large proportion of the several hundred food handlers whom I have had cultured with negative results may be intermittent carriers, infecting from time to time people not intimately associated with them." This reasoning amounts to the following: A. has access to the food supply of B., C., D., E., etc.; B., C., and D. develop typhoid fever, and A. is found to carry the typhoid bacillus; therefore A. has infected B., C., and D. If A. is not found to be infected, he may be an intermittent "carrier" and still responsible. As a matter of administration, to segregate A. in the former and to keep an eye upon him in the latter case are plainly correct courses; but the logician will certainly say that what has been shown is not causation but correlation, and that if, as Dr. Howard hints and others have hinted, the carrier state is extremely common, then the argument from correlation is not so impressive as it appears.

The whole point of such sequences as that of the grandmother and her descendants, and of the negro cook and the college girls, depends upon the assumption that the odds against the mere fortuitous concurrence of half-a-dozen cases of typhoid and the presence of a carrier are enormous. In our opinion, that assumption may be safely made, and the carrier assigned a definite and not unimportant part in the etiology of typhoid as a sporadic or minor epidemic disease. To go further and to see in the carrier the prime factor of dissemination of typhoid would be unwarrantable, and we think that the following words of Dr. Howard have more than local application: "Now that the City Fathers, after many years of fumbling, have finally made those general sanitary provisions necessary for the reduction of the incidence of typhoid fever to a comparatively low level, in the old twenty-four wards, and the obvious may be set to one side, the public health administrator of an inquiring turn of mind may turn himself to the much more interesting and important problem of determining the less obvious or hidden means of transmission of the disease."

ADVANCED LECTURES IN LONDON.

ANNOUNCEMENTS recently made by the University of London of advanced lectures on medical subjects illustrate an improvement that is quietly being made in the facilities for advanced medical students and visitors to London. The lectures are specially addressed to the former, but they are open to others interested in the subject without

¹ Johns Hopkins Hospital Bulletin, vol. xxxi, Nos. 354-5, August-September, 1920.

free or ticket. All the courses, with one exception, are given by teachers in London medical schools; the one exception is the lecture to be given on June 8th at the house of the Royal Society of Medicine by Dr. H. J. Hamburger, Professor of Physiology in the University of Groningen; the lecture will deal with "permeability in physiology and pathology," and Professor E. H. Starling, C.M.G., F.R.S., will be in the chair. On June 13th Professor F. R. Fraser will begin a course of four lectures at St. Bartholomew's Hospital on digitalis: the first will deal with the principles of the therapeutic use of the drug; the second with its use in the cardiac arrhythmias; and the third with its effect in cases with normal cardiac rhythm; in the fourth lecture digitalis glucosides and allied substances will be described. Four advanced lectures in pharmacology will be given at the Royal College of Surgeons by Dr. Edward Mellanby, Professor of Pharmacology in the University of Sheffield, on June 6th, 7th, 13th, and 14th. The first two lectures will deal with elements of diet aiding and preventing the proper calcification and growth of bones and teeth, and the third with dietetic conditions affecting the development of normal and hyperplastic thyroid glands and the application of the experimental results obtained to exophthalmic goitre. In the fourth alcohol as a food-drug will be discussed. A course of four lectures on recent advances in experimental embryology will be given at the Imperial College of Science, South Kensington, by Dr. E. W. MacBride, F.R.S., Professor of Zoology in the College. The first lecture will be given on June 7th; in it Professor MacBride will discuss the nature of the process of fertilization, artificial parthenogenesis and allied matters; in the second he will deal with the three stages in a normal life-history and the dependence of the formation of organs on the "internal environment." This subject will be continued in the third lecture, which will contain a review of the effects of thyroid extirpation and of thyroid feeding on tadpoles, of the relation of the pituitary to growth in tadpoles, and an analysis of the effects of the thyroid, as seen in *Axolotl* and perennibranchiate *Crodele*. The effects produced by the external environment as worked out by Kammerer will then be described, and, finally, the bearing of the results on the theory of evolution will be discussed. Dr. Charles Porter, M.O.H. St. Marylebone, will begin a course of four lectures on recent developments in legislation for the prevention of disease, at University College, Gower Street, on May 30th. The first lecture will deal with the history of the subject, the second with directly preventive legislation, the third with indirectly preventive legislation, and the fourth with legislation of the future. The lectures are given at 5 p.m., except those of Dr. Porter's course, which will be given at 5.30 p.m.

PROTECTION OF RADIOLOGICAL WORKERS.

The X-Ray and Radium Protection Committee, to the proposed formation of which we made reference a few weeks ago, has now been constituted; it has been established to investigate the means of protecting workers with x-rays and radium from the injurious effects which have been observed, especially those on the skin and blood. The Chairman is Sir Humphry Rolleston, K.C.B., M.D. The members are: Sir Archibald Reid, K.B.E., C.M.G., Radiologist to St. Thomas's Hospital; Dr. Robert Knox, Radiologist to King's College Hospital and the Cancer Hospital (representing the British Association for the Advancement of Radiology and Physiotherapy); Dr. S. Gilbert Scott, Radiologist to the London Hospital; Dr. Stanley Melville, Radiologist to St. George's and to the Brompton Chest Hospitals (representing the Electro-therapeutic Section of the Royal Society of Medicine); Dr. Harrison Orton, Radiologist to St. Mary's Hospital; Mr. Cuthbert Andrewes (representing the Röntgen Society); Professor S. Russ, Physicist to Middlesex Hospital (representing the Institute of Physics); Dr. G. W. C. Kaye, O.B.E. (representing the National Physical Laboratory); Dr. J. C. Mottram, Pathologist to the Radium Institute. Dr. Melville is acting as honorary secretary. The Committee held a preliminary meeting on May 18th at the house of the Royal Society of Medicine. The Committee has appointed a subcommittee to draw up a short statement on the means for the protection of the worker, giving advice as to the position of x-ray rooms, their ventilation and cubic space, and on the need for making and observing rules governing the hours of work, outdoor exercise, and holidays of workers. It is hoped that this statement may shortly be issued as a leaflet. The Committee intends further to collect data bearing on the effect of irradiation with particular reference to protection; to carry out special research, if necessary; to act in a consultative and, possibly, advisory capacity; and to publish reports from time to time.

RESEARCH IN RADIO-THERAPEUTICS.

A SCHOLARSHIP has been founded at the Manchester Royal Infirmary primarily for the investigation of the claims made, especially in Germany, for the intensive x-ray treatment of cancer. The anonymous donor, however, desires that the inquiry shall include the study of the cancer problem from any point of view that may arise, and also an inquiry into the precautions that should be taken for the protection of persons working with highly penetrative rays. The scheme under which the scholar will work has been framed by a committee, consisting of Sir William Milligan, Professors H. R. Dean and W. L. Bragg, Dr. A. Burrows, Dr. Powell White, Mr. James Watts, and Dr. A. E. Barclay. Dr. C. C. Anderson has been appointed the first scholar, and will visit various centres where the intensive method is in use. He will then return to Manchester to carry on the investigation in collaboration with other workers, who will attack the problems arising from the pathological and physiological standpoints. It is intended that the first visit should be made to Erlangen, but if time permits the scholar will afterwards visit Freiburg, Berlin, and Mannheim, and certain centres in France, Holland, and Sweden.

COLONEL WILLIAM HUNTER, C.B.

On Friday, May 20th, at the Imperial Restaurant, a complimentary dinner was given to Colonel William Hunter, C.B., M.D., in recognition of his scientific work, especially in regard to preventive medicine. It was felt by his colleagues and professional friends that Dr. Hunter's retirement from the active staff at Charing Cross Hospital formed a suitable occasion to express their appreciation both of himself and of his work. The dinner was presided over by Mr. George Verity, chairman of the governing body of Charing Cross Hospital, who was supported, in addition to the other speakers, by Sir Arbutnot Lane, Sir Frederick Mott, Sir Herbert Waterhouse, Mr. Walter Spencer, and a large company. The chairman spoke of the affection and admiration felt for their guest by all who knew him. He referred, with a layman's diffidence, to some of the landmark's in Dr. Hunter's career—his researches in diseases of the liver, his discovery of the importance of oral sepsis, his labours in freeing the Serbian army of typhus, and his work as President of the War Office Advisory Committee for the prevention of epidemic diseases in the Eastern war areas—and expressed the regard felt for him by all who had been associated with him during his many years' service at Charing Cross as Physician and Dean, and also as historian of the Hospital and Medical School. Sir Thomas Barlow said that a man who had done what William Hunter had done should be told by his friends and colleagues what they thought of him, and of his gift to humanity. In his pioneer work on pernicious anaemia, its prevention and arrest, he took the true scientific line;

he grappled first of all with causation, knowing that treatment would follow from study of the natural history of the disease. In attacking the problem of typhus in the East, he concentrated his efforts on lice, the carriers of infection, applying fresh knowledge to new and difficult conditions. They were proud to think that all this work had been done by a general hospital physician. Dr. William Hunter, in replying to the toast of his health, made a modest and charming acknowledgement of the tribute paid him by his old friends and colleagues. He expressed the regret with which he gave up his work at Charing Cross after a quarter of a century. Touching briefly on his war experiences between April, 1915, and December, 1919, he spoke of the loyal support given by his bacteriological colleagues and his good friends the Serbians in overcoming typhus. As he read it, the lesson of his war work was that prevention must be grasped as a whole. Sir James Galloway, in proposing the toast of "The Visitors," added a word of genial appreciation of "Willie Hunter" on behalf of the staff of Charing Cross. This note was echoed by Sir William Hale-White, who said that praise from the brethren of one's own profession, those who knew and understood, was the only praise worth having. Sir Humphry Rolleston, who also responded, preferred to regard himself as an honorary host rather than as a visitor. For very many years he had admired the whole-minded way in which their guest pursued his aims, and these included all branches of preventive medicine. The health of the Chairman was proposed by Sir John Bland-Sutton, who sketched in bold outline the qualities needed for a good hospital chairman, and in so doing described Mr. Verity.

THE AMERICAN MEDICAL ASSOCIATION.

The annual meeting of the American Medical Association takes place this year at Boston, Massachusetts, from June 6th to June 10th, and it is expected that nearly 10,000 persons will visit Boston in connexion with the meeting. Special trains and special railway fares from all parts of the United States have been arranged for members of the Association who are attending. The different scientific sections are to meet on June 8th, 9th and 10th. The Sections on the Practice of Medicine; Obstetrics, Gynaecology and Abdominal Surgery; Laryngology, Otology and Rhinology; Stomatology; Pathology and Physiology; Nervous and Mental Diseases; Urology; and Preventive Medicine and Public Health will hold their meetings during the mornings. The Sections on Diseases of Children; General and Abdominal Surgery; Ophthalmology; Miscellaneous Topics; Pharmacology and Therapeutics; Orthopaedic Surgery; Dermatology and Syphilology; and Gastro-enterology and Proctology will meet during the afternoons. On June 6th and 7th a series of special clinics have been arranged in the Boston hospitals. In connexion with the scientific exhibition, it has been suggested that many subjects presented before the sections in papers could, if there were time and opportunity, be demonstrated by specimens, material, instruments, apparatus, charts and the like, or by lantern slides, or "moving picture talks," and it is proposed that the authors should be encouraged to supplement their papers with exhibits. If the exhibit is movable it may be taken to the meeting place of the Section at the time of the reading of the paper, and then returned to its place in the Exhibit Hall. The exhibits have been arranged in three main divisions—medicine, surgery, and pathology. It is pointed out that "still" exhibits are of little value; what is desired are personal demonstrations or explanatory talks by someone who is interested in, and can teach, the subject. The *Journal of the American Medical Association* remarks that the primary object is to bring to the minds of the profession attending the meeting a knowledge of the newer things in the progress of scientific medicine, and thus not to limit the presentation of such subjects to the comparatively

small groups of physicians or surgeons attending a particular section. In addition to the scientific work which is to be carried on at the Boston session there are many social features, while the fact that the Pilgrim Tercentenary takes place at Plymouth (U.S.A.) immediately after the close of the scientific meeting suggests that it will be attended by many members of the association.

MEDICAL INSURANCE AGENCY.

A MEETING of the Committee of Management of the Medical Insurance Agency was held at the house of the British Medical Association, 429, Strand, on May 12th, when the chairman, Dr. G. E. Haslip, presented a report on the working of the agency for the year 1920. There had been, he said, substantial progress in all classes of insurance, including a large increase in the life business. Special pains were taken to arrange policies of life insurance suitable to the needs of medical practitioners. Children's policies, either in the form of thrift policies or educational endowments, appealed, it was found, strongly to the profession. Business in motor car insurance was done both with the tariff offices and in respect of a special doctor's policy granted by Lloyds' underwriters. Though the amount of business was satisfactory, it was felt that it might easily be larger were the advantages offered by the agency better known. During the year the sums returned by way of rebate to those holding policies of various kinds through the agency amounted to £1,453, or £493 more than in 1919. This is a direct saving to the insured, and since the agency was founded, in 1907, the sums saved to the profession have amounted altogether to well over £9,000. The expenses of the agency show an increase of £158, due in part to the increased cost of printing, postage and stationery, and in part to the salary now paid to the clerk to the agency. After allowing for the rebates and agency expenses the balance-sheet, certified by the auditors, Messrs. Price, Waterhouse and Co., shows a surplus available for distribution among medical charities amounting to £1,959. At intermediate meetings held in May and December, 1920, grants amounting to £1,015 were made to medical charities, leaving an unallotted balance of £976. It was now resolved to make grants of 300 guineas each to the Royal Medical Benevolent Fund, the Royal Medical Benevolent Fund Guild, and Epsom College Benevolent Fund. The objects those who founded the agency placed before themselves were, first to assist medical men to insure against various risks on the best possible terms, and secondly, to use part of the commission earned by the agency to help medical charities. Both objects have been attained. As a result of the distribution this year the total sum paid to medical charities by the agency since its foundation is £7,380. Mr. W. E. Warne, who has been agent and secretary since the death of Mr. Guy Elliston (who was one of the founders), is retiring, but the agency will continue to have the advantage of his experience, as he has accepted a seat on the Committee of Management. Mr. P. N. Adamthwaite, who has worked in the office of the agency for some years, has been appointed agent.

THE BIRTH OF EDWARD VI.

CAESAREAN section takes its name, of course, from the reputed birth in this manner of Julius Caesar, but the operation is of still more ancient origin. Pliny, in mentioning it, says that Scipio Africanus (B.C. 237) was so born, as, according to Ovid, was Aesculapius. There is in England a persistent tradition, supported by contemporary ballads, that Queen Jane Seymour, the third queen of King Henry VIII, was delivered by Caesarean section of the prince who became King Edward VI. The story is told, and the evidence sifted, in an interesting article by Dr. S. D. Clippingdale, in the spring number (Vol. xxviii, No. 1, New Series) of the *Journal of Obstetrics and Gynaecology of the British Empire*, although he arrives at no definite conclusion as to the truth or otherwise of the tradition. Queen Jane was approaching her thirtieth

year when the confinement occurred, on October 12th, 1857, at Hampton Court, and she died twelve days later. There is a story, not unsubstantiated, of how when it was explained to him that, owing to the protraction of the labour, an operation was necessary—the choice apparently lay between craniotomy and Caesarean section—the King replied: "Save the life of the child, for another wife can easily be found." This sentiment may have been influenced by State policy, but it does not to modern ears compare favourably with Napoleon's in like case: "Save both lives if you can, but if you cannot save both lives, save the life of the Empress." Early on the day of her death a certificate was sent to the Privy Council, signed by three apothecaries and three Court physicians, reporting that "Yesterday afternoon she"—the Queen—"had a natural lax for reason whereof she began to lighten"—this perhaps indicates the presence of peritonitis—"and (as it appeared) to amend and so continued till towards night. All this night she hath been very sick and doth rather appare than amend." There is no mention of operation in this report or in a letter which the Queen addressed to the Privy Council, two days after her confinement, to announce the birth of a prince, and evidently the Queen progressed well for at least a week, when her condition took an unfavourable turn. Dr. Clippingdale suggests that on the removal, after eight or ten days, of the wrappings with which the patient had been swathed, septic peritonitis may have been induced. Whatever was the actual cause of death, however, the popular belief, as shown by the ballads quoted in the article, was undoubtedly that it resulted from Caesarean section.

TUMOURS AS MALFORMATIONS.

Is a thoughtful article with the non-committal title "Studies on tumour formation," Dr. G. W. Nicholson,¹ Lecturer in Morbid Histology at Guy's Hospital, first exposes the weak points in the current definitions of a tumour, and then asserts that the reason why these definitions break down is that tumours do not differ in any essential character from the other tissues of the body. He maintains that it is only by regarding tumours as aborted organs that their structure, growth, and development can be understood; there is, he argues, no distinction between tumours on the one hand and accessory organs or malformations on the other; thus he holds that the nature of a mammary fibro adenoma is more truly expressed by terming it "a malformed breast," that "giant parathyroid" is quite as good a description as parathyroid adenoma, and that a secondary squamous-celled carcinoma would be more accurately described as "malignant skin." Reversion to the appearances seen during the development of the tissues is a characteristic feature of most tumours; thus the malignant "adeno-sarcoma" of the kidney, not uncommon in early life, habitually recapitulates the normal development of that organ and was rightly entitled "malignant embryonic kidney" by Trappe. To the phenomena characterizing malignancy Dr. Nicholson proposes to devote a future article, and to this we shall look forward, for, after all, the point that chiefly interests the bulk of the profession is how to obviate the harmful effects of tumours, whatever their exact nature may be, and, if possible, to substitute prevention for problematic cure. But to return to Dr. Nicholson's argument: it is often urged that tumours do not perform any function, or, if so, that it is useless; there are, however, many examples with histological evidence of considerable physiological activity in tumours, especially those in connexion with secreting glands; tumours, in fact, do their best in this direction, but as abortive organs, often without ducts, they fall short of success. To define a tumour as autonomous and deriving its nourishment from the body does not

distinguish it from an organ such as the liver or from the foetus *in utero*. Dr. Nicholson therefore concludes that in their structure, manner of growth, and functions tumours do not differ essentially from other tissues; they are merely less perfect; they merge into, and indeed are, malformations. Incidentally, Dr. Nicholson declares war on the term "endothelioma" as a convenient category for tumours of difficult classification, and expresses repentance for having described six examples in 1907.

THE ANNUAL MEETING AT NEWCASTLE.

THE provisional programme for the forthcoming annual meeting of the British Medical Association at Newcastle-upon-Tyne was printed in last week's SUPPLEMENT, together with further particulars regarding accommodation for visitors at Newcastle. Later issues of the SUPPLEMENT will contain the revised programme of arrangements and forms for notification of attendance to be filled in by members intending to be present at the annual meeting. The title of Sir Thomas Oliver's special address on industrial medicine, to be given on Wednesday, July 20th, at 8 p.m., is "Industrial Hygiene; its Rise, Progress and Opportunities." The lecture will be open to those of the commercial and industrial classes who are interested in the subject.

THE MEDICAL CURRICULUM IN GERMANY.

IN an opening address delivered to the German medical congress which met in Wiesbaden last month, Professor G. Klemperer of Berlin expressed the view that the economic disabilities under which Germany was labouring—disabilities which were likely to continue—would make it necessary to shorten the medical curriculum. He suggested that in future it would be possible to allot only four terms to what are called in this country the preliminary and intermediate subjects—physics, chemistry, anatomy, and physiology. Six terms, he thought, would be required for the clinical subjects. During the first year of clinical study a medical student should attend a course of practical nursing, and during the two following clinical years should be engaged in practical work in the various hospital departments. After condemning the too great length of vacations, he maintained that by replacing technical and theoretical studies by intensive practical work it would be possible to give up the "practical year" hitherto required after the passing of the final qualifying examination. Under existing economic conditions, he said, the recently qualified student could not afford to spend a year in unremunerative hospital work; this requirement, moreover, was a serious obstacle to early marriage. Turning to more general questions, Professor Klemperer laid stress on the absolute necessity of maintaining free choice of doctor. The relation of doctor to patient was strictly personal, and State control would destroy the highest ideals of the medical profession. Finally, he had a fling at women doctors; he had, he said, no objection to them in theory, but doubted profoundly whether their physical strength would be equal to the exacting demands of medical practice.

DANGEROUS DRUGS REGULATIONS.

THE Regulations, dated May 20th, 1921, made by the Secretary of State for Home Affairs, under Section 7 of the Dangerous Drugs Act, 1920, are published in the *London Gazette* of May 24th, but the Report of the Committee which has been advising the Home Secretary on these Regulations is not yet available. We hope to deal with the Regulations and the Report next week.

LORD CAVE'S committee of inquiry into the finances of the voluntary hospitals has held meetings again this week, but it is not expected that the report will be completed for presentation before the end of the month.

Scotland.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

SIR JOHN R. FINDLAY, who presided at the annual meeting of contributors to the Royal Edinburgh Hospital for Sick Children, said, in moving the adoption of the annual report, that the expenditure had increased by leaps and bounds, and although the public had responded by increasing their subscriptions the increase was below the increase in expenditure. The hospital had always had to draw upon benefactions in the form of legacies, but the percentage met from this source had gone up at the present time to between 41 and 45 per cent. Edinburgh was perhaps more fortunate than London, where there was a large number of competing hospitals, with comparative lack of personal interest on the part of the public in any particular hospital. Scotland, however, was divided into comparatively small districts, and the inhabitants of these particular districts took a pride and a personal interest in the hospitals which, he thought, would enable them to maintain the voluntary system much longer than elsewhere. What they might hope for was that if any assistance was given to the voluntary hospitals it would not be in a form which would have the effect of undermining the voluntary system. Colonel Newbigging seconded the adoption of the report, which was agreed to. Lord Ashmore, in moving a resolution commending the hospital to the liberality of the public, said that he was struck by the fact that there was a kindly appreciation of the institution on the part of many of the public works, and of one or two of the large co-operative societies.

EDINBURGH UNIVERSITY ROLL OF HONOUR.

It is a melancholy business for the survivors of a generation to peruse the memorial of their fellows who are dead, even though their deaths were glorious and deserving of memory. As we turn over the pages of this volume,* recognizing so many names and so many faces of student days before the war, we realize more poignantly the blight that has been cast upon a whole generation. So many are dead without our having known it, so many are dead whose deaths we knew too well. Edinburgh has always prided herself on being a university for all the world, and on the long roll appear names from every corner of the globe, and from Highland parish schools as well as from Eton and Winchester. Young and old are there together, from the fresher of one term's standing to Sir Hay Donaldson, who was 60 when he was drowned with Lord Kitchener, and Colonel James Clark, K.C., who was killed in action in France at the age of 56. The names of two ladies, both medical graduates, appear—Dr. Elsie Inglis, who died as the result of her memorable work in the Balkans, and Dr. Marian Wilson, who died at Royaumont, in France. The names of famous athletes one expects to find on such a roll as this, but with them in equal honour are the names of men whose field was the laboratory or the study. So, with Bedell-Sivright—the dashing forward of twenty-two internationals—J. L. Huggan, Eric Milroy, Alfred Taylor, J. H. D. Watson, and many another, we have A. D. Darbishire, the brilliant university lecturer on genetics, who was a private in a Highland regiment before he gained a commission in the Artillery, John Handyside, the lecturer on logic and metaphysics, and H. H. Norton, the Wesleyan minister who as an R.A.M.C. private was killed at Gallipoli. There, too, are W. G. Porter—who gained a D.S.O. as an Artillery major—and Denis Cotterill, the surgeons, and G. H. Melville Dunlop, the physician, who would to-day so surely have been carrying on in Edinburgh the tradition of the medical school, while among the undergraduates who have fallen are the honoured names of Bayley Balfour, Cathcart, and Schafer.

On the Roll of the Fallen appear the names of 944 members of the university, with brief accounts of their academical and military careers, illustrated in nearly all cases by photographs, while in the Record of War Service are some 7,000 more names. At first, we believe, it was intended that this Record should include all forms of

national service, but various difficulties arose, and as it was realized that such services stood in a different category from services in the field the intention was abandoned. It may be regretted, however, that for this reason the names are excluded of the Edinburgh graduates who held high office in the State during the war, while the names are included of some honorary graduates—such as General Botha and Sir Alfred Keogh—who otherwise had little connexion with the University. At the end of the volume is a list of the orders and decorations won by members of the University. Five Victoria Crosses. Although none of the medical graduates, two had been medical students. The volume, which is sumptuously produced, has been edited by Major John E. Mackenzie, who was adjutant of the University Officers' Training Corps throughout the war, and who has pursued an arduous task to a most successful end.

We print below the names of the medical graduates of the University who are included in the Roll of the Fallen:

Captain J. G. Anderson, M.C., Colonel J. H. E. Austin, Dr. A. K. Baxter, Dr. Guy Beattie, Fleet Surgeon D. R. Bedell-Sivright, Colonel C. M. Begg, Captain J. H. Beilby, Captain J. A. T. Bell, Captain T. H. S. Bell, Captain J. W. Bingham, Captain H. W. Binks, Surgeon-General W. G. Birrell, Captain E. J. Blair, M.C., Captain G. S. Blandy, M.C., Captain G. V. Bogle, Captain G. S. Brock, Captain W. Brownlie, M.C., Lieutenant J. E. Brydon, Captain W. H. Calvert, Lieutenant D. Campbell, Lieutenant J. Cattanach, Fleet Surgeon W. R. Center, Captain S. McA. F. Cesari, Captain J. J. P. Charles, M.C., Lieutenant A. L. Christie, Captain I. A. M. M. Clarke, Captain D. Cotterill, Captain A. Cowe, Captain T. F. Craig, Lieutenant J. Crockett, Captain D. C. Crole, Lieutenant M. W. Danzig, Captain J. Davie, Captain R. H. Drennan, Major C. W. Duggan, Captain R. W. Duncan, Major G. H. Melville Dunlop, Captain J. J. Dykes, Major E. J. Elliot, Surgeon W. Everett, Captain G. D. Ferguson, D.S.O., Colonel C. C. Fleming, D.S.O., Major E. G. Ford, Captain J. D. Forrester, Captain J. W. Frew, M.C., Lieutenant N. M. Gavin, Lieut.-Colonel W. A. Gibb, Captain W. E. Gibbons, Captain D. Gilmour, Captain E. M. Glanville, Major R. G. Gordon, D.S.O., Captain J. P. Grant, Colonel B. B. Grayfoot, C.B., Lieutenant R. D. L. Greene, Captain A. Groenewald, M.C., Lieutenant G. W. Guthrie, Captain T. E. Guthrie, Captain F. Hardie, Lieut.-Colonel N. E. J. Harding, Major A. C. Hartley, Captain T. Hayhurst, Lieutenant F. G. Heard, Captain J. H. Helm, Captain N. J. Hofmeyr, Lieut.-Colonel M. Holmes, Staff Surgeon A. O. Hooper, Surgeon H. J. Hopps, Second Lieutenant S. C. Huddleston (Black Watch), Lieutenant J. L. Huggan, Captain G. S. Husband, D.S.O., Colonel J. Hyslop, D.S.O., Lieutenant C. C. Iles, Dr. Elsie M. Inglis, Captain P. P. Inglis, Major R. C. Irvine, Lieut.-Colonel T. W. Irvine, Captain A. Jasnowsky, Major F. N. Johns, M.C., Major F. M. Johnson, Captain G. E. Keith, Lieut.-Colonel M. A. Ker, Captain S. A. Kury, Captain E. W. Lawrence, Major H. Ruthven Lawrence, M.C., Captain G. M. Lervack, Surgeon C. W. Lewis, Captain D. P. Lindsay, Captain S. J. Linzell, M.C., Croix de Guerre, Captain A. G. S. Logie, Captain A. P. Low, Captain H. T. Lukyn-Williams, Lieutenant G. H. Lunan, Surgeon H. J. McCaw, Captain L. T. McClintock, Lieut.-Colonel W. McConaghy, D.S.O., Surgeon J. S. D. McCormack, Captain J. Macdonald, Captain I. Macdonald Brown, Captain R. G. McElroy, M.C., Captain I. Macfarlane, Major J. G. Macindoe, Captain J. C. Macintosh, Surgeon D. S. MacKnight, Captain I. Macpherson (Seaforth Highlanders), Captain P. C. Macrae, Major W. A. Malcolm, Lieutenant J. Marshall, Major A. A. Martin, Captain J. McD. Matheson, Colonel H. G. Melville, C.I.E., Lieut.-Colonel A. J. A. Menzies, D.S.O., Lieutenant G. H. Middleton, Staff Surgeon G. R. Mill, Lieutenant A. I. Miller, Captain R. Montgomery, Surgeon G. B. Moon, Colonel A. H. Moorhead, Surgeon A. A. Morison, Major J. Morris, M.C., Captain S. H. Morris, Captain W. Morrison, M.C., Captain K. K. Mukerji, Major R. F. T. Newbery, Major J. McC. Orme, M.C., Captain J. P. Pattison, Lieutenant A. Philip, Captain A. Z. Phillips, Captain G. S. Pirie, Major W. G. Porter, D.S.O. (R.F.A.), Captain O. D. Price, Dr. E. F. T. Price, Captain H. H. Proudfoot, Captain A. M. Pryce, Captain W. D. Reid, M.C., Lieut.-Colonel J. C. Renton, Captain H. Rendell, M.C., Lieutenant M. J. Richardson, Major W. R. Ridley, Captain W. Ritchie, Captain A. B. Robertson, Captain R. C. Rogers, Lieut.-Colonel A. A. Ross, Lieutenant A. B. Ross, Lieut.-Colonel C. S. Rundle, Dr. J. F. Selkirk, Lieutenant J. W. Senter, Major M. C. C. Seton, Captain J. J. Shannon, Lieutenant J. G. Sharp, Captain J. C. Simpson, Lieutenant D. W. Sinclair, Captain C. E. H. Smith, Captain H. G. Smith, Captain H. M. Spoor, M.C., Surgeon A. R. Steel, Major N. W. Stevens, Lieut.-Colonel W. M. Sturrock, Major W. Symington, Colonel F. A. Symons, D.S.O., C.M.G., Captain A. S. Taylor, Captain H. Y. C. Taylor, Captain C. T. Tennant, Major B. C. Tennant, M.C., Major F. G. Thompson, Lieut.-Colonel F. W. Thomson, Lieutenant A. J. J. Tough, Surgeon S. N. Toutmin, Surgeon A. E. Turnbull, Captain J. K. Correspondence.

BLOOD TRANSFUSION IN HAEMORRHAGIC DISEASE OF THE NEWBORN.

SIR,—In your issue of April 9th, 1921, p. 527, Mr. Douglas Laurie cites a severe case of melæna neonatorum successfully treated by blood transfusion. It should be realized more generally that blood transfusion, if used in time, is an absolute remedy for these cases of haemorrhagic disease of the newly born. In a few cases horse serum or human blood injected subcutaneously may be used successfully, but to ensure a cure blood transfusion is beyond any question the best and most reliable procedure. In the Hospital for Sick Children, Toronto, we prefer the syringe cannula (Lindeman) method,¹ but where this is not feasible the citrate method may be used.

The freshly introduced blood not only stops further bleeding, but replaces the lost blood. We consider the cure of the haemorrhagic condition to be accomplished practically at the end of the transfusion. The amount to be given varies with the weight of the infant, but a good working rule is not to exceed 15 c.cm. per pound of body weight. The transfusion is completed usually in ten to twelve minutes, the actual time of injection being about three to four minutes for 100 c.cm. of blood.

Mr. Laurie lays too great emphasis on the difficulty of exposing a suitable vein and in having to use a hypodermic needle to inject the blood. This difficulty is very readily overcome by exposing under local anaesthesia the internal saphenous vein where it crosses the internal malleolus. If this vein cannot be seen, it can usually be palpated and feels like a small vas deferens when rolled under the thumbnail. If it cannot be located before cutting down, it can be exposed by an incision which crosses its course. This vein is much thicker walled than the elbow veins and is more constant in its position. Small, sharp-pointed, curved eye or manicure scissors are used to make an oblique cut in the vein after applying and steadying the vein with a distal ligature. The lumen is dilated with the tips of the scissors. It is surprising how large a cannula this vein will accommodate, and I use a 1½ in. No. 17 tempered, gold serum needle with the point (but not the bevel) rounded off. A 2 in. rubber tube, armed with metal tip fitting the hub of the needle, makes the injection of blood simple.

Following transfusion, if the bleeding has been from the bowel, old dark blood is passed during the first twenty-four hours. The necessity of obtaining a compatible donor is not as great as in the case of older children or adults, as in many of the infants we have found that the agglutinins are not established at birth, or if so, are apparently weak. When the father is the only donor available, I have used him without preliminary grouping tests. If circumstances permit of it, it is safer to have a compatible donor or a universal donor (Group IV, Moss grouping) as Mr. Laurie did.

In a series of 40 cases of haemorrhagic disease of the newly born transfused at this hospital and elsewhere, four died, two of these from associated sepsis of the umbilical cord and one from intracranial haemorrhage, which was extensive before transfusion. The fourth case had bled profusely for two days, and had stopped breathing half an hour prior to admission to hospital. During that time artificial respiration had been carried out, and although the pulse was present on admission, the patient was too far gone to benefit by transfusion.—I am, etc.,

BRUCE ROBERTSON,
Assistant Surgeon, Hospital for Sick Children,
Toronto, Canada.

April 29th.

HEART-BLOCK AND THE ADAMS-STOKES SYNDROME.

SIR,—In a letter published in your last issue (p. 755) Sir Clifford Allbutt gives the pathological findings of a case which exhibited the Adams-Stokes syndrome, but nevertheless showed an apparently healthy myocardium.

I am afraid the report of my paper read before the members of the Liverpool Medical Institution was not sufficiently explicit. My opinion was based not on pathological but on electro cardiographic evidence. My personal experience of these cases is as follows:

Cases of block, complete and partial, which, apart from the lesion of the *a-v* bundle, gave a perfectly normal cardiogram, never exhibited the Adams-Stokes syndrome. In complete block these cases show a slow but a regular pulse rate. On the other hand, so far as my experience goes, cases which have exhibited Adams-Stokes syndrome have shown some aberration in the Q.R.S. complex—such, for instance, according to Lewis, were evidence of a defect in one of the branches of the *a-v* bundle. Apart from the disturbance of the conductivity of the main bundle there was evidence that other structures of the heart were affected.

The impression one gains from such cases is that the defect in the main bundle is really not the primary lesion, and that, on the contrary, some degenerative changes starting elsewhere have gradually affected this structure. Accordingly more often than not the degree of block is not very pronounced in such cases. But the degenerative changes of the heart muscle must be extensive in them, since not only the main bundle but one of the branches is affected. Moreover, clinically the prognosis of cases exhibiting these aberrations is very grave, if we except those instances in which the defect is due to some removable cause, such as syphilis.

But the interesting feature of these cases which has a bearing on Sir Clifford Allbutt's letter is the pathological findings. Although the gravity of the clinical symptoms must lead to the assumption of the presence of extensive pathological changes, yet a *post-mortem* examination in many instances revealed scarcely a pathological lesion (Lewis and others).

But to return to our main theme: I do not wish to be misunderstood. I do not say that the Adams-Stokes syndrome does not appear under any other circumstances than in cases which show this particular aberration. What I maintain is this: A lesion limited to the main *a-v* bundle does not give rise to an Adams-Stokes syndrome. In cases which exhibit this syndrome in addition to the defect in the main bundle some other factor comes into play. It is conceivable that in a damaged heart muscle the refractory period of the ventricle may become longer than normal after a temporary exhaustion, or a structure might become affected which is the seat of the origin of the ventricular rhythm.

Clinically and pathologically, cases exhibiting the syndrome show so many different features from ordinary heart-block that they ought to be treated as a separate entity. Ordinary block is a disease with a clean-cut pathology and a definite clinical picture. On the other hand, a great deal of work will still have to be done before the cardiac mechanism which produces the syndrome becomes clear. Evidently Sir Clifford Allbutt's case belongs to a great number of heart cases in which the present pathological methods are inadequate to discover subtle changes in some vital structure, which, in accordance with clinical evidence, must be in existence.—I am, etc.,

Liverpool, May 20th.

I. HARRIS.

THE PREVENTION OF PUERPERAL INFECTION.

SIR,—As a general practitioner of twenty-seven years' experience, I feel bound to make comments upon Dr. Blair Bell's very able paper printed in the BRITISH MEDICAL JOURNAL for May 14th.

The use of gloves in midwifery, with many other men, I deprecate; they diminish the tactile sensibility of the fingers, they lead to inevitable carelessness, and the hands are clumsily washed because the antiseptic feels that they are going to be covered and it matters not. The result is that the left hand, still infected, presses on the fingers of the right glove and they are fouled. It is considered unnecessary to dip the gloves in an antiseptic; therefore, if there

be any infectious material about the vulva it is carried into the vagina without any inhibitor.

Consider, then, the conditions of an ordinary confinement. A small room with one nurse, who has to give the chloroform! Almost inevitably the patient must be moved or non-sterilized articles touched. In a nursing home or a hospital this is not necessary, but very few of the 800,000 births each year occur in hospital. No! Teach the men to wash their hands in mercury biniodide, and little else matters. When I was "clarity" at Guy's Hospital twenty-five years ago and whilst I was . . . such a thing as puerperal fever was never . . . not occur.

The unskilled students were soaked in perchloride, and yet they examined the patients continually for hours and hours. The universal experience, as far as I have heard it, is that the cases that have fever are those where little has been done and that those where there has been great interference escape infection. There is a tendency to-day to accept too readily the dicta of the aseptic people. Antiseptics are urgently required and produce brilliant results, as the experience at Guy's and other great hospitals illustrates. Even surgeons operating do not wash their hands as they did in the old days, so that frequently their gloves are infected, as their fingers, unclean, escape through holes torn in the gloves. Sterilized aprons are very charming, but dangerous. A man says they are clean, and will touch them, but the mischief has been done—the apron has touched the bed. He will not dream of touching his clothes; he feels and knows that they are dirty. After a widespread though numerically small experience, I say: Teach the accoucheurs to wash and to use mercury biniodide for everything. The present use of a few drops of lysol is useless and dangerous, because the accoucheur depends on it. There must be a bowl of biniodide 1 to 1,000 in which he can dip his hands every few minutes.—I am, etc.,

London, S.W., May 17th.

VAUGHAN PENDRED.

Sir,—In your leading article you say, "Many a woman would escape infection if the attendant only arrived as the child was passing over the perineum, so that no vaginal examination could have been made." This was exactly what happened in one of the only half-dozen or so cases of puerperal infection it has been my lot to see in thirty years of general practice. I have been in a rural practice twenty-eight years, and before that I was two years in colliery and town practice. I am perfectly certain not more than half a dozen cases of puerperal infection have been seen by me in some 1,400 odd cases of midwifery. Perhaps I ought to be ashamed to admit I have never possessed a pair of rubber gloves, nor worn a pair at a confinement, and only twice seen the vulva shaved—much to the disgust of the patients, who swore they would never allow it again. Up to a year or two ago I never hesitated to make as many vaginal examinations as I liked, just to see how the labour was progressing, and never saw any harm come of it. Forceps have been employed in about 12.5 per cent. of my cases, which include one craniotomy and many where turning was required, and so far as I can remember no case of infection occurred after any bad case, except a few cases of *puerperal alba dolens*. The main point I wish to . . . I have not seen a death from puerperal infection of any kind. The most serious cases of infection that have come my way have followed abortion—incomplete abortion, of course—and although I have seen many of these and some very ill, I have not seen a death. I think I can see a parallel between infection after abortion and infection after delivery at term.

It has struck me often that some of these patients ought to have become badly infected, for many a time I have seen shreds of putrid membrane passing out of the vagina after what was regarded as a perfectly normal labour, yet all went well with ordinary treatment, which consisted of keeping the vagina clean. I believe there is sometimes far too much meddling with the interior of the uterus, and if activities there were confined to simple douching little harm would come. The great majority of my midwifery has been done in cottages and under very cramped conditions and often insanitary surroundings. I fail to see what use overalls and rubber gloves can be to a man in my position, where one cannot often procure more than a couple of basins in the house and little or nothing to prepare a bed

properly for a lying-in woman, and often no help beyond some old woman neighbour; and yet all these cases which ought, according to all the laws of obstetrics, to go wrong do not! My precautions are limited to carbolic acid, lysol and abundance of soap and water.

I expect I would be classed by my friends the consultants with those who are known as "dirty doctors"; but I have no intention to depart from my technique or, as perhaps they would say, the absence of it. I am not ashamed of my record, and claim no merit for anything I am saying, except that it is the truth.

One word more, and it is this: I would not care to be in the position of a young, newly-fledged practitioner full of up-to-date learning on obstetrical technique if he examined a patient in labour per rectum and not per vaginam. I can imagine his being ordered out of the house as not knowing his job! No, Sir, our investigators will have, in my opinion, to look elsewhere for their sources of infection than the dirty doctor and dirty nurse. I do not dispute that they may occasionally be at fault. In the light of practical experience, however, it would seem that they are not so frequently to blame as some authorities would have us believe, or how does it happen I have been so immune from puerperal infection in my practice? I believe cases of this disease will go on occurring now and again in hospital and out of it with every precaution, because I believe we will have the autogenetic origin always with us, and I do not see how we are going to prevent it.—I am, etc.,

May 15th.

"OLD FASHIONED."

REFRACTION WORK AMONG SCHOOL CHILDREN.

Sir,—I write to support Dr. A. E. Larking's advocacy of utilizing both subjective and objective methods of estimating refraction errors (BRITISH MEDICAL JOURNAL, May 21st, 1921, p. 759), and I agree with him that three average cases per hour is as many as can be done really thoroughly.

Mr. Bishop Harman's method (with hole in blackened disc and a marked diameter—BRITISH MEDICAL JOURNAL, May 7th) is interesting and should be useful occasionally, but I differ entirely from him if his contention is, as I gather, that subjective testing (I mean as an adjunct) is useless in children "from, say, 5 to 14 years." He says "it is no use asking a child whether this or that glass is better than another, or what difference this lens of a fraction of a diopetre makes to clearness of vision." Quite so, but that is not really the way in which test-types are used. It is useless to say, "Is this glass better than that?" but if you have three or four cards and take care that lines which are supposed to correspond are not composed entirely of easily-read letters on one card and of difficult ones to read on another, then it is possible and useful to find with which glass the child reads (not says he sees) best.

Both retinoscopy and subjective testing contain sources of possible error, and it is obviously wise to check one method by the other in all cases where this can be done. Of course this takes longer to carry out, but real accuracy requires it, and if one has spent a few hours in fitting children with wrong glasses it is not much consolation to feel that one did as many as possible in the time.

In no class of patients, particularly in the class likely to attend eye clinics, can reliance be placed on complete cycloplegia being obtained by the home use of atropine in any form, and retinoscopy unconfirmed by subjective testing, performed on a patient with incomplete cycloplegia, is a poor thing on which to stake professional reputation and the patient's future comfort—and learning and earning capacity.

Mr. Harman is such an expert that in his hands unchecked retinoscopy will, no doubt, usually lead to a correct prescription; but the possibility of error is present even in his case, and in others less adept will frequently result in bad mistakes.

Mr. Harman's advice to learn on young adults with well-developed facilities is excellent, but a complete series of such is not usually available for the beginner. I began by learning all I could of retinoscopy and subjective testing in a hospital eye department and then doing the work for my own private patients, telling each of them to come back if not perfectly comfortable; and I would advise that

school medical officers should first learn all they can in hospital, and that when they start work in the schools should begin by selecting the older children, do both retinoscopy and subjective testing, and be content at first if they do one in forty-five minutes. One correctly prescribed for is worth any number incorrectly prescribed for.

I should like to enter a plea for the doctor doing the frame-fitting. This in the hands of an optician is frequently even worse than his sight-testing, and it can be done accurately in one minute a case when you know how, and are properly equipped.

It is unnecessary and even injurious to order very large, and especially round, lenses "to prevent the child looking over them." If the glasses are correct he will not want to look over them (if required, atropine can be continued for a week until he becomes accustomed to them), and if you make him an object of ridicule with glasses which are more than ordinarily disfiguring, he will probably wear them in his pocket.—I am, etc.,

Altrincham, May 22nd.

ARTHUR T. BLASE.

Sir,—The letter by Dr. Arthur E. Larking under the above heading in the JOURNAL of May 21st, p. 759, calls for some comments.

First, the statement that a certain education committee expects its school medical officer to do at least "six" refractions in an hour. If this does not come under the heading of "sweated labour" I should like to know what does! Secondly, I am afraid Dr. Larking has taken Mr. Bishop Harman far too literally. Thirdly, the statement that Mr. Bishop Harman has let the secret out of the bag is a piece of sarcastic criticism that must not go by unchallenged.

It would appear that Dr. Larking accuses an accomplished ophthalmic surgeon of slipshod methods in refraction work. I am sure that Mr. Bishop Harman never intended it to be taken for granted that he, or any other refractionist, always prescribes glasses from retinoscopic findings alone without confirmation by subjective tests. Mr. Bishop Harman, and any other competent refractionist, would always confirm his retinoscopy, where possible, by the subjective method, especially if there be astigmatism present of more than one dioptre. There is no need to waste time testing subjectively in hypermetropia. It is advisable to apply subjective methods also in cases of myopia. Now, so far as astigmatism is concerned, one has a little latitude in cases that take a cylinder of one dioptre or less, but in cases requiring a cylinder from one dioptre upwards then one must place the cylinder as near as possible in the proper meridian.

For the above reason no ophthalmic surgeon would ever dream of prescribing lenses from retinoscopy alone without subjective verification in cases where this is possible. If the patient is too young for subjective sight-testing, then one has no alternative but to correct any refractive error by retinoscopy alone. One meets with many such cases, but they should be examined by a thoroughly competent refractionist alone. It requires very great experience before one is competent to write a prescription for glasses with any degree of accuracy from retinoscopic examination alone. It can be done, but any capable refractionist would much rather verify his findings subjectively.

There is no "letting secrets out of the bag." It is just a matter of experience and ability. It is quite possible to test the eyesight of six children in an hour, but even an expert like Mr. Bishop Harman would not like to do this regularly for two hours at a time. I have often done it, and in addition have measured each child's face with a faco-rule giving the exact measurements for spectacle frames, but I would not do it regularly for £1,000 per annum. If a person were to keep up an average of four cases an hour, and do each case properly, such a school medical officer would be a person any education authority ought to be proud of; and if they ask for six cases to be done per hour, then they are asking for faulty work.

If an education authority makes a stipulation for six cases an hour, then such authority should be reported to the British Medical Association, in order that it might take action to put down such sweating methods.—I am, etc.,

Middlesbrough, May 23rd.

J. PARKINSON HIGHAM,
Ophthalmic Surgeon.

THE PREPARATION OF SCIENTIFIC PAPERS.

Sir,—The letter of Sir James Barr in your issue of May 14th is so full of literary lapses, not to say of vulgar errors, that at first it suggested a deliberate trap for editors and proof readers; but if this is not so, you, Sir, have surely scored rather cruelly by printing it uncorrected.

Literary style is an elusive thing and not easy of definition. A style may be as rugged as you please, like Carlyle's; and yet be clear and forcible, but there is a peculiar awkwardness about the sentences of Sir James Barr which an attempt to read them aloud makes evident.

To take a few of his sentences serialim, let us begin with this: "This discovery necessitated me verifying the references," and, in the matter of style, note the whole sentence: "This discovery necessitated me verifying the references, and as I have ceased subscribing for this Council's periodical since its price was raised . . . this letter has been delayed."

A few lines lower we meet this dark sentence:

"The BRITISH MEDICAL JOURNAL seems to be no less unfortunate" (no less than what?) "in its contributors, but it is not quite plain how they display their disregard, as a negative is rather difficult to display unless it be that of a photograph." Honestly, the meaning of this cryptic utterance is beyond my powers of elucidation; it is certainly "not quite plain." I have tried it by referring "they" to the contributors, and again by taking "they" to refer to the BRITISH MEDICAL JOURNAL, but the result is equally bewildering.

Split infinitives, I suppose, we must put up with, and the child was only two years old, which is certainly some excuse. When she is older she will know better.

Referring to "unwashed hands," Sir James says: "There is no verb to unwash, whence then the past participle?" This forcible argument had better have remained unwritten. There is no verb "to unwrite," whence then the past participle?

Take another sentence: "If photographs were excluded, there would be no danger that the inclusion of inessential details in the background leading to confusion." True, it only needs the substitution of "of" for "that" to make sense, but you, Sir, as above mentioned, have been cruel.

Again: "An editor should have a fair working knowledge of his own language, and be able to spell, as the latter qualification [that is, being able to spell] is not an uncommon defect in many otherwise well educated writers." Here again a writer with a real appreciation of grammatical nicety would have written "is a not uncommon defect," which is not quite the same thing as "is not an uncommon defect."

Finally, the first two words of Sir James Barr's rules illustrate delightfully the very grammatical error against which he solemnly warns us in the second rule. "Only write," that is to say do not paint, nor draw, nor sing, but only write, "when you understand what you are going to write about." What Sir James presumably wished to inculcate was "Write only when you understand, etc.": but this is not what his rule, as written, ordains.

It is the old story of Dean Alford, recurring after an interval of sixty years.—I am, etc.,

Bromsgrove, May 17th.

H. CAMERON KIDD.

** We have received a number of other letters criticizing Sir James Barr's literary style, but the points seem, in the main at least, to be covered by the above letter and that published last week. It appears, therefore, unnecessary to insert any more.

ELEMENTARY PSYCHOLOGY IN GENERAL HOSPITAL TEACHING.

Sir,—I have read with much interest Dr. William Calwell's address on the above subject published in your last issue, p. 736. I suggest that Dr. Calwell could accomplish his object by using his influence to secure the establishment of an out-patient department for mental cases at the Royal Victoria Hospital, Belfast. There are departments for such patients at practically all the "teaching" hospitals in London, and my colleagues at these hospitals will, I am sure, agree with me that the amount of material is almost more than they are able to

cope with, and affords excellent instruction for the students. It is my experience that it is an infrequent event for the "mental" cases to be of so severe a character as to require to be sent to a mental hospital.—I am, etc.,

R. H. STEEN,
Out-patient Physician in Psychological Medicine,
King's College Hospital.

Dartford, May 23rd.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation, held on May 20th, it was agreed, on the recommendation of the General Board of Studies, to appoint a University Lecturer in Physics as applied to Medical Radiology, in connexion with the Special Board for Medicine, for a period of five years, with a stipend of £100 a year.

The following medical degrees were conferred:

M.B., B.Ch.—C. C. Okell.
B.Ch.—Man Wong; R. Hilton.

UNIVERSITY OF SHEFFIELD.

At a meeting of the Council of Sheffield University, on May 13th, Dr. F. E. Wynne (M.O.H. Sheffield) was appointed Professor of Public Health in succession to Dr. Harold Scurfield. The appointment is in accordance with the policy of the University of associating the public health work of the city with instruction given at the University. Mrs. May Mellaub, M.Sc., was appointed demonstrator of dental histology in the department of physiology, and Drs. Ferguson, Wilson, Eric Stacey, E. Barnes, and R. St.L. Brockman demonstrators in the department of anatomy.

The Council adopted a resolution expressing its regret at the death of Emeritus Professor R. J. Pye-Smith and placed on record its appreciation of his long and distinguished services to the University as a member of the council and as professor of surgery.

The Council's thanks were accorded to the Sheffield Panel Committee for its gift of war bonds and war stock of the nominal value of £1,000 for the purpose of equipping a research field laboratory in connexion with the medical faculty of the University.

UNIVERSITY OF EDINBURGH.

A MEETING of the University Court was held on May 16th.

Mr. Francis Gordon Bell, M.D., Ch.B., F.R.C.S. Eng., was appointed assistant examiner in systematic surgery in succession to Mr. R. C. Alexander, resigned.

Among the resignations intimated was that of Dr. John Beard as lecturer in comparative embryology and vertebrate morphology.

Mr. L. V. R. Becker was reappointed for a further period of six months from April as clinical tutor to the surgical out-patient department of the Edinburgh Royal Infirmary.

Recognition was granted to Dr. John D. Comrie as an extra-mural lecturer in the practice of physic.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Primary Fellowship Examination.

THE following candidates have been approved at the first professional examination for the diploma of Fellow:

L. H. Appleby, D. C. G. Ballingall, F. G. Beatty, A. Blackstock, C. E. Bond, G. A. Brookes, H. A. Brookes, G. G. Bruce, J. T. Burrell, G. M. Cameron, C. H. Carlton, S. M. Cohen, J. R. M. Collie, R. S. Corbett, R. C. Davenport, C. O. Davies, S. N. Deboo, M. R. Flynn, G. N. Golden, L. B. Goldschmidt, W. D. Hart, G. T. Henderson, C. A. Horder, L. G. Housden, M. V. Hurley, S. P. Jacobson, J. Jemson, A. R. Jones, N. A. Jory, N. E. Laurence, M. A. Laurie, K. W. Leon, A. R. Lister, C. A. Lupton, Gladys H. Marchant, J. Maxwell, Ruth E. Millar, W. Miller, L. Morris, T. D. Overend, J. A. Panton, C. M. Pearce, N. A. M. Petersen, J. E. Purves, B. T. Rose, J. P. Ross, Violet I. Russell, J. R. Smith, M. J. Smyth, W. O. Stevenson, Hilda N. Stoessiger, G. C. Swanson, D. B. Walker, A. D. Wall, E. C. Warner, F. W. Watkyn-Thomas, H. B. White, S. H. Woods.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

Fellowship Examination.

At a meeting of the College, held on May 18th, the following seventeen successful candidates out of fifty-six entered, who passed the requisite examinations between January 10th and 15th, were admitted Fellows:

J. P. Blockley, J. W. Burns, A. C. Clark, W. A. Cochrane, T. Colley, C. C. H. Cuff, C. W. Graham, J. M. Hyde, V. J. F. Lack, T. Lindsay, Helen M. McMillan, W. Mercer, Mabel L. Ramsay, G. C. Seantlebury, S. Scoullar, G. H. Stevenson, S. G. Whitfield.

The Bathgate Memorial prize, consisting of bronze medal and set of books, has, after a competitive examination in materia medica, been awarded to Mr. J. M. McLintock, and the Ivison Macadam Memorial prize in chemistry, consisting of bronze medal and set of books, to Mr. J. Harkness.

CONJOINT BOARD IN SCOTLAND.

THE following candidates, having passed the requisite examinations, have been admitted Diplomates in Public Health:

R. B. Watson, R. B. Stewart, C. C. Brown, J. S. Elliot, J. B. Plummer, D. A. Cadman, A. I. Meek, J. Singh, J. C. Simpson, N. S. R. Lorraine, C. Milne, G. G. S. Johnston, D. T. M. Laige, G. P. Taylor, Jane E. Hay.

Obituary.

GEORGE BLUNDELL LONGSTAFF, M.A., M.D., F.R.C.P.

THE death took place on May 7th, at his residence, Highlands, Putney Heath, of Dr. George Blundell Longstaff, in his 72nd year. Dr. Longstaff was the son of Dr. G. D. Longstaff of Wandsworth, and he was educated at Rugby, at New College, Oxford, where he graduated M.A. and M.B. in 1876, and at St. Thomas's Hospital, where he was a Mead medallist. He further obtained the diplomas of M.R.C.P., M.R.C.S., and the D.P.H. in 1877. He became a Fellow of the Royal College of Physicians in 1888, and took the degree of M.D. in 1891. Dr. Longstaff, so far as we are aware, never engaged in the practice of medicine, but he found his medical knowledge of value, at the time, for instance, of the Jamaica earthquake, for, happening then to be in Jamaica, he did a great deal of medical work among the people of the island. Dr. Longstaff devoted his life to philanthropic, municipal, and scientific work. He was for many years a member of the London County Council, and acted as chairman of the Building Act Committee. He served on many committees of the Charity Organization Society, had been a Poor Law guardian, was a Justice of the Peace, and a member of the Wandsworth District Board of Works. His father had been the first chairman of the Wandsworth Library Commissioners, and he himself joined the Board and succeeded his father as chairman. An ardent entomologist, he was a great collector, and the Hope Collection in the Oxford University Museum has been more than doubled by contributions he presented to it. He was the author of *Butterfly Hunting in Many Lands*, which was published in 1912.

A member of many learned societies, he had been vice-president of the Royal Statistical Society and of the Entomological Society, and was an authority on the analysis of animal and vegetable oils. Dr. Longstaff had served as one of the old Volunteers, and when the special constables were enrolled in 1914, at the outbreak of war, was one of the first to join; he became the first Chief Inspector of the Wandsworth Section, and attended keenly to his duties until ill health compelled him to resign in 1917. He was twice married, his second wife being a Fellow of the Geological Society, who was awarded the Murchison Geological Fund in 1893, and who has made many contributions to the publications of the Geological, Linnean, and other learned societies. Dr. Longstaff's philanthropic, educational, political, and scientific activities made him one of the best-known and most highly esteemed public men in South London, where his loss will be greatly felt.

WE regret to announce the death, at Stewarton, Ayrshire, on May 8th, of Dr. THOMAS WATT, who was one of the best known medical practitioners in Paisley, where he had practised for over thirty-five years. Dr. Watt was educated at Glasgow University, where he first graduated M.A., and later qualified in medicine by graduating M.B., C.M., in 1886. He was senior visiting physician to the Royal Alexandra Infirmary, Paisley, and medical officer to the Post Office. He took a particular interest in the campaign against tuberculosis and in the establishment of sanatoriums for the borough and county. He had paid much attention to the question of a wholesome milk supply, and had travelled in Germany, Denmark, and Holland with a view to extending his knowledge on this subject. Dr. Watt, who had been in poor health for some time, was 59 years of age; he is survived by his widow, a daughter, and two sons, one of whom is carrying on his father's practice at Paisley.

LIEUT.-COLONEL THOMAS RANKIN MACDONALD, Bengal Medical Service (retired), died at Inverness on May 8th. He was born on May 17th, 1853, educated at Edinburgh, where he graduated M.B. and C.M. in 1876, having pre-

viously taken the L.R.C.S. Edin. in 1875, and at Vienna, and entered the I.M.S. as surgeon on March 31st, 1880, becoming lieutenant colonel after twenty years' service, and retiring on June 20th, 1900. While on furlough prior to retirement he took the F.R.C.S. Edin. in 1899, and after retiring was for a time in partnership with his uncle, the late Dr. MacLeod of Hawick, after which he settled in Inverness. He served in the Egyptian war of 1882, was at the battle of Tel el Kebir, and received the medal with a clasp and the Khedive's bronze star. He was also one of the I.M.S. officers deputed to Egypt for special cholera duty in 1883. The rest of his service was mostly passed in civil employ in Burma and Bengal.

Medical News.

H.R.H. THE DUKE OF YORK will open King George's Sanatorium for Sailors, a branch of the Seamen's Hospital Society, Gretnach, at Braimshot, Hants, on July 12th.

MADAME CURIE has been presented by the President with a gram of radium subscribed for by women of the United States. She has received the honorary degree of LL.D. from the University of Pennsylvania and that of M.D. from the Women's Medical College, Philadelphia.

DR. RUSSELL J. RAYNOLDS has been appointed radiologist to Charing Cross Hospital, in succession to the late Dr. W. Ironside Bruce.

THE annual dinner of the Harveian Society will be held on Wednesday, June 22nd, at 7.30 p.m., at the Café Royal, Regent Street, W.

THE medical conference arranged by the Industrial Welfare Society will be opened at 51, Palace Street, London, S.W., on June 2nd, at 10.30 a.m., when Dr. R. M. Wilson will introduce the subject of "Medical service in industry." In the afternoon the subject of "Health problems in industry" will be discussed by Professor E. L. Collis, Dr. T. M. Legge, and Dr. Halford Ross.

A MEETING convened by Dr. Marie Stopes will be held at Queen's Hall on May 31st, at 8.30 p.m., to discuss "Constructive birth control." The speakers will include Dr. Jane Lorrimer Hawthorne and Dr. C. Killick Millard.

DR. W. J. HOWARTH, C.B.E., medical officer of health for the City of London, has been elected President of the Society of Medical Officers of Health for the session 1921-22; he will take office in October next. The honorary fellowship of the society has been conferred on Dr. Alfred Hill, formerly medical officer of health for the city of Birmingham, "for long and distinguished services to preventive medicine and public health administration." Dr. Hill, who has just entered his 96th year, was president of the society in 1886 and 1887. The annual provincial meeting of the Society will be held on Saturday, June 11th. Members will assemble at the house of the Society at 10.30 a.m., and proceed by motor coach to Hatfield House, which will be visited by invitation of Lord Salisbury. Afterwards the party will be entertained at luncheon at Welwyn Garden City by the president of the Society, Dr. F. E. Fremantle, M.P. The Welwyn housing and town planning schemes will be inspected, and Mrs. Fremantle has invited members to tea at Bedwell Park. Members who intend to be present are asked to give early notice to the Executive Secretary, 1, Upper Montague Street, Russell Square, W.C.1, stating if they will be accompanied by ladies; 10s. 6d. should be forwarded for each motor coach ticket.

AT the Marylebone Police Court, on May 9th, Hugh Mouton, of Park Lane (formerly of 15, Cavendish Place), appeared to answer three summonses under the Venereal Diseases Act, and one summons under the Medical Act, issued against him at the instance of the Medical Defence Union, Limited. The facts upon which the prosecution relied were admitted by the defendant, and the magistrate, after hearing counsel and without calling witnesses, imposed a penalty of £30 in respect of each offence under the Venereal Diseases Act, and £20 in respect of the offence under the Medical Act, with five guineas cost on each summons; and sentenced the defendant to two months' imprisonment in default of payment of the fines and costs within seven days.

THE Inland Revenue authorities received in the financial year ending March 31st, 1920, the sum of £1,332,661 in payment of patent medicine labels in Great Britain alone, an increase of £266,967 over the amount received under the same head in the previous financial year. The duty on

the labels varied from 3d. to £2, according to the price of the medicine. The number of licences issued to makers or vendors of patent medicines in Great Britain during the financial year 1919-20 was 41,671, yielding a net revenue of £10,421; the corresponding figures in the previous year were 39,675 and £9,920.

THE summer meeting of the Section of Laryngology of the Royal Society of Medicine will be held on June 2nd, 3rd, and 4th. On the afternoon of Thursday, June 2nd, and on the morning of Friday, June 3rd, a number of papers will be read and cases shown, while on the afternoon of June 3rd a number of special demonstrations will be given, followed by the ordinary meeting of the Section. A dinner will take place in the evening at the Trocadero Restaurant. On the morning of Saturday, June 4th, the laryngological staffs of University College Hospital, the Central London Ear and Throat Hospital, and other hospitals will perform special operations.

THE British Congress of Gynaecology and Obstetrics will hold a meeting at the Queen's Hotel, Birmingham, on Friday and Saturday next, June 3rd and 4th.

THE Belgian Minister of Sciences and Arts, in response to the request of the Faculty of Medicine, has resolved to create a chair of psychiatry at the University of Ghent.

DR. KENNETH L. ECKLSTERN, pathologist to the French Hospital, London, who served during the war as a medical officer in the French army, has received the honour of Chevalier of the Legion of Honour.

DR. CHARLES ABADIE of Paris was entertained at a banquet on May 12th in celebration of his medical jubilee.

THREE post graduate courses, conducted by the pediatric, obstetrical and gynaecological, and otorhino laryngological clinics, respectively, will be held in the University of Naples, commencing on May 30th and continuing for two to three months. The courses will be of a practical character, and the numbers will be limited.

DR. HERBERT WALK, president of the American Medical Association, has been appointed by President Harding first Assistant Postmaster General.

DR. CHAUVET, a former clinical assistant of Professor Moure, has been appointed to take charge of the department of otorhino laryngology in the faculty of medicine at Strasbourg.

AN exhibition of radiographs will be held by the Röntgen Society in the Royal Photographic Society's rooms, 35, Russell Square, W.C., during the month of June. The exhibition will be open daily (Sundays excepted) from 10 a.m. to 5 p.m., and all who are interested are invited to attend.

A POST GRADUATE course in medicine, particularly on the application of laboratory methods to diagnosis, will be held during July next at the Hotel Dieu, Paris, under the direction of Professor Maurice Villaret, with the co-operation of a large staff. The course will begin on Monday, July 4th, and will include thirty-two lectures, and demonstrations, taking place three daily. The fee is 150 francs, and a certificate will be given at the end of the course. Particulars may be had from the secretary of the Faculty of Medicine, University of Paris. In connexion with this course a tour of study has been arranged, from July 9th to 17th, to the spas of the Pyrenees the detailed programme of which can be obtained from Dr. Dausset, at the medical clinic of the Hotel Dieu.

THE report of the Home Service Ambulance Committee for the first quarter of the year shows that the institution of an ambulance service in the country has been justified by the work that the vehicles have accomplished. It is now two years since the inauguration of the scheme as part of the peace work of the Order of St. John and British Red Cross Society, and the successive reports prove that as the existence of the ambulances has become known, steady progress has been made in their use for the transport of the sick. The number of cases carried during the March quarter was 11,393, being 3,629 in excess of the total for the previous quarter. The Committee is recalling the old ambulances used during the war as they become unfit for service and replacing them by new ambulances of a lighter type, this change, it is hoped, will have several advantages, including a reduction in the cost of maintenance.

ACCORDING to the New York Medical Record, the prohibition director for Illinois has announced that each of the 2,000 druggists of Chicago may withdraw 200 gallons of whisky and 200 gallons of wine every three months. The commissioner of internal revenue has announced that this quantity could be increased if the druggists could show that they really needed more liquor to supply the demand. At this rate Chicago will use 3,200,000 gallons of wine and whisky a year for her 3,000,000 inhabitants.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the British Medical Association and British Medical Journal is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin. *Dr. J. J. Rutland*, Dublin; telephone, 4737, Dublin, and of *Rutland Square*, Edinburgh (telegrams: telephone, 4361, Central).

QUERIES AND ANSWERS.

SELF-NOTIFICATION.

"Q." who was suffering from malaria and trench fever, notified the M.O.H. on the official form; he has not received payment. He asks whether a medical practitioner is ever justified in notifying himself as a case of infectious disease, and if so, whether he is entitled to a fee.

"A." The Infectious Disease (Notification) Act, 1889, and subsequent General Orders require a medical practitioner upon becoming aware that a person upon whom he is in medical attendance is suffering from certain specified diseases, to send to the medical officer of health of the district a notification of the case. The local authority must pay a fee to the medical practitioner for this service without further demand on his part. Failure on the part of the practitioner to send the notification renders him liable to a fine. It is conceivable that the practitioner might himself be the patient and that he might be in "medical attendance" on himself, in which case he must send a notification to the medical officer of health and is entitled to the fee.

SUMMER PRURIGO.

DR. H. B. BINKS (Merthyr Tydfil) asks for advice in the treatment of a boy of 12, pale and freckled, who has suffered every summer for the last five years from a vesicular eruption on the exposed parts of the face and neck. The vesicles are at first the size of a pinhead; they gradually become more opaque and turbid, and then show dark in the centre. Unless reinfecting they dry off without leaving a visible scar.

"A." A dermatologist to whom the question has been referred writes: The history of this patient suggests that he suffers from a form of summer prurigo, a disease first described by the late Sir Jonathan Hutchinson. The fact that he is freckled is a point slightly against this diagnosis. Freckles are the natural reaction of the skin to the stimulus of strong light, and their presence should protect it against inflammatory lesions such as those described. Treatment is not easy; care should be taken to shield the face and neck by wearing a wide-brimmed hat, and the use of a red veil has been recommended; this might be a practical measure for a girl but hardly for a boy. The discomfort arising from the eruption can be allayed by the use of the ordinary cooling lotions containing calamine, zinc oxide, and glycerin. There is a tendency for the eruption to lessen with the advent of adolescence.

INCOME TAX.

"T. A. S." bought, in March, 1921, in conjunction with a partner, a practice in which he had been acting as assistant.

"A." The two partners are assessable as for 1921-22 on the basis of the three years' profits of the practice to December 31st, 1920, or March 31st, 1921, if more convenient. Those profits were the earnings of the practice after the salary to "T. A. S." had been deducted, and the Acts contain no provision which would authorize the Revenue authorities to compute the profits in any other way. For the purpose of calculating the tax due, the gross assessment so arrived at should be shared between the present partners on the same basis on which their actual profits are shared.

"A. A." who is tuberculosis officer to a county council, receives an allowance for expenses computed on the basis of the cheapest means of conveyance, tram, bus, etc.; in fact, he uses a motor car and so saves several hours a week. He asks if he is entitled to deduct from his salary his out-of-pocket expense on the car.

"A." The emoluments in question fall under Schedule E and expenses can be deducted only if "incurred wholly, exclusively, and necessarily in the performance of the duties." We think that our correspondent could not establish to the satisfaction of the Commissioners hearing the appeal that the additional expense of locomotion incurred by him was necessary in the performance of the duties, in which case his claim would fail for lack of proof.

LETTERS, NOTES, ETC.

"E. G. C."—Tanned human skin becomes so dark that without a microscopic examination it would not be safe to decide if it was that of a white or a coloured person. If our correspondent could furnish a small piece, we will endeavour to have the question determined.

DIFFERENTIAL STAINING OF CARCINOMATA.

DR. A. G. SHERA, in a further letter which may well end this correspondence, writes that he did not accuse Dr. Kayvett Gordon of inexperience, but only that "the mature opinion of an expert histologist would be more satisfying." The expert histologists in this country, in the opinion of one well able to judge, may, Dr. Shera says, be counted on the fingers of two hands. The method referred to is being tried out in expert hands, so that Dr. Shera feels that the last word in criticism is not yet uttered.

SIGNS AND SYMPTOMS.

"CLINICIAN" writes, with reference to a recent correspondence on this subject: Evolution is essentially a physiological (defensive) process. It is physiological at first, secondly anatomical, and finally a fusion of both. It is a property or process of the biological (that is, living) world, in which man is the Z of its alphabet. When man is attacked by disease we have "warfare in the human body," and when this war is heard by the patient and told to his doctor, it is a symptom of its presence; and when it is felt by the patient or his doctor, it is a physical sign of its presence.

TWINS.

DR. C. A. ENSOR (Anerley Park, S.E.) writes: A few days ago, whilst inquiring into the family history of a patient, I elicited the following facts: (1) Her mother had had twins thrice; (2) three of the patient's sisters have had twins twice; (3) she herself has had twins three times, but at birth was a "singleton."

PARABOLIC REFLECTOR LAMP.

THE safety parabolic reflector oil lamp made by Mr. J. Bruce (232, Borough High Street, London, S.E.) has been used in Guy's Hospital for the past twenty years, and is well known to a good many members of the medical profession. Inspection of the sample we have lately received suggests that the quality of the workmanship and material is well maintained. By the use of the plated parabolic reflector a bright light can be concentrated on any part of a room. The lamp should be especially useful in country consulting rooms and surgeries where electric light is not available; it can be used either as a hand lamp or hung on a wall. The price of the nickel-plated form is 10s. 6d., post free to addresses in the United Kingdom.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 32, 33, 34, 35, 36, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 35, 37, and 38.

THE appointment of certifying factory surgeon at Peterculter (Aberdeen) is vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line...	0 1 6
Whole single column (three columns to page) ...	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive posts payable letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

614 Aneurysms of the Cystic and Splenic Arteries

HÖGLER (*Wien. Arch. f. inn. Med.*, August 1st, 1920) records two cases of aneurysm of abdominal arteries in which, for the first time on record, a diagnosis was made during life and confirmed by the autopsy. In the first case, aneurysm of the cystic artery in a man aged 51, with rupture into the bile ducts, the diagnosis was based on the following symptoms: (1) Attacks of pain resembling biliary colic occurring on the slightest provocation and radiating to the pabie region, (2) severe intermittent gastro-intestinal haemorrhage after the attacks; (3) the auscultatory findings—namely, a systolic murmur in the region of the gall bladder at the time of the haemorrhage. In the second case, aneurysm of the splenic artery in a woman aged 61, the diagnosis was based on the following symptoms: (1) Attacks of pain in the left hypochondrium and in the back, improved by lying on the right side, (2) a pulsating tumour in the left hypochondrium; (3) a systolic murmur over this tumour, (4) the x ray findings—which showed an extra ventricular pulsating tumour and an ovoid shadow the size of a walnut in the region of the tumour. Höglér emphasises the fact that the auscultatory findings were the decisive factor in the diagnosis. Although 16 cases of aneurysm of the splenic artery are on record, in none of them is any mention made of the auscultatory findings, while among the 47 reported cases of aneurysm of the hepatic artery, in only one case, which was reported by Bickhart and Schumann, was the diagnosis made during life owing to the presence of a systolic murmur over a tumour in the hepatic region, but no autopsy was made. Höglér therefore recommends that in all obscure abdominal diseases systematic auscultation of the abdomen should be carried out.

615 Hydrocephalus Complicating Cerebro-spinal Fever

WORSTER DPOUGHT (*Journ. Neurol. and Psychopathol.*, February, 1921) points out the importance of early recognition of hydrocephalic symptoms, since speedy and repeated lumbar puncture, following the period of serum administration, will often prevent chronicity. When symptoms of internal hydrocephalus occur and no fluid follows lumbar puncture the only effective method is drainage of the subarachnoid space above the obstruction in the dorsal or cervical region, the latter being usually the more successful. As soon as the skin is penetrated the stylet should be removed in order that the cerebro spinal fluid may escape directly the needle penetrates the subarachnoid space, thus avoiding injury to the cord. Should lumbar, dorsal, and cervical puncture all prove unsuccessful, obstruction from fibrino purulent exudate having occurred at the foramen magnum, sphenoidal puncture may be tried before tapping the lateral ventricles. By introducing the needle at a point 2 mm. external to the supraorbital notch the most external portion of the sphenoidal fissure is reached, and on withdrawal of the stylet cerebro spinal fluid escapes if the hydrocephalus is generalized in the cranial cavity. Failing this, drainage of the ventricles may be tried, in infants through the lateral angle of the anterior fontanelle, or in older children and adults by Keen's or Kocher's method. Instead of trephining, the author has successfully punctured through a hole drilled in the skull over Keen's point, with equally good results and less shock than after trephining. Each side should be operated upon alternately. Incision of the corpus callosum and prolonged drainage through a wide opening has been advocated, one successful case being recorded.

616 Cerebral Haemorrhage in Childhood

CONTI (*La Pediatria*, February 15th, 1921) remarks that all writers are agreed that cerebral haemorrhage is very rare in childhood. Sclerosis of the arteries and the formation of miliary aneurysms, which are the principal anatomical factors, are absent at this age. There is thus an absence of resistance to the blood stream and of a rise of arterial blood pressure and hypertrophy of the left ventricle which occurs when the patient's general condition of nutrition renders it possible. Some writers, however, such as Symnitzky, assert that arterio sclerosis in children is not so rare as is generally thought. Cerebral

haemorrhage appears to be more frequent in males, just as in adult life. Conti records a case in a female infant, aged 18 months, who was admitted to hospital with nephritis, probably of malarial origin, and developed left hemiplegia, preceded by convulsions, the day before death. The autopsy showed a large haemorrhage in the right cerebral hemisphere, and degeneration of the vessel walls on microscopical examination. The haemorrhage is attributed by Conti to the existence of chronic nephritis.

617 X-Ray Treatment of Aene Vulgaris.

WITHEBROE and REWLER (*Med. Record*, March 19th, 1921) deprecate the use of local applications of drugs during x ray treatment of aene vulgaris because it is essential for uniform and permanent results that the x rays should diminish the size of the sebaceous follicles without affecting the skin and its appendages, whereas the combined effect of irritating drugs and x rays produces a radio dermatitis with subsequent atrophy, wrinkling, and telangiectasia. With the patient prone and the head sideways, the eyes, eyebrows, eyelashes, and the hair over the temporo frontal region are protected with lead foil, and the tube is centred over the zygoma, and an exposure of a quarter of 1 skin unit is given weekly to each side of the face, and continued for two or three weeks after new lesions have ceased to form. Twelve to sixteen treatments constitute a regular course, and if the chest and back are involved these are treated in the same way, overlapping of exposure being avoided by protection with lead foil. Dietetic and constitutional measures should be maintained after such full course of x ray treatment.

618 A Peculiar Fever of Infancy

GRUFFE and DONAR (*Amer. Journ. Dis. of Children*, March, 1921) record observations upon a peculiar fever of infancy, probably due to depletion of the water reserve of the body. In infants in whom the water has been depleted by persistent vomiting or by unsuitable thickened foods, a temperature is noted which appears to be due to dehydration, there being a direct relation between the temperature curve and the water intake. Careful estimates of the number of red and white cells, haemoglobin, and specific gravity of the blood, confirmed this view. Although an infectious or bacterial origin of the fever cannot be entirely eliminated, because of the possibility of the changed condition being responsible for an absorption of intestinal bacteria, most of the evidence is against such a toxæmia, since there are no accompanying toxic or gastro-intestinal symptoms, and there is evidence of a reduced water content of the blood during the febrile period. The observations have a practical bearing upon the treatment of severe vomiting conditions in infancy and on the use of thickened foods.

619 Bronchial Asthma

ALEXANDER and PADDOCK (*Arch. Intern. Med.*, February 15th, 1921), from a study of a series of cases of bronchial asthma with a view to correlating any findings common to all, found that an outstanding feature was an almost constant sensitiveness to pilocarpine and epinephrin. While normal people gave very little or no response to half a grain of pilocarpine, vagotonic patients, with or without asthma, reacted in varying degrees. To epinephrin the majority reacted with an abnormal rise in blood pressure and signs of pallor, tremor, or even rigor, showing increased sensitiveness to the drug. Those cases which reacted excessively were found to be relieved by 0.25 c cm. of 1 in 1,000 of epinephrin chloride, which is a much smaller dose than that usually employed, so that the larger doses generally used may be greatly in excess of requirement and caution is therefore urged against its promiscuous use in asthma.

620 Quinidine in Heart Disease

JENNY (*Schweiz. med. Woch.*, March 24th, 1921) has given quinidine in 18 cases of auricular flutter associated with arrhythmia perpetua or delirium cordis. Only in one case did this remedy fail in its object. As the detailed records of his cases show, very different quantities of the drug were given to obtain the desired effect. In one case a total dose of 0.5 gram was sufficient to restore the pulse to its normal state. In this case the auricular flutter had lasted three weeks and the recovery effected was maintained over

an observation period of five months. In another case as much as 15.5 grams had to be given before the arrhythmia could be controlled. Thus, while in one case the action of the drug was demonstrable after three hours, in another its effects could not be detected till the tenth day of its administration. The dosage recommended by the author is, to begin with, 0.3 gram. The amount may be slowly increased, and as much as 2 to 3 grams may be given in the twenty-four hours. Only after ten to fourteen days' unsuccessful treatment should the inability of the drug to control the symptoms be accepted. Tinnitus and ocular disturbances are indications for discontinuing the drug at once. But, provided strict medical supervision is exercised, such symptoms as abdominal discomfort, headache, giddiness, and increased pulse rate may be ignored.

621. Treatment of Erysipelas by Injections of Novocain and Adrenaline.

NICOLAS (*Zentralbl. f. Chir.*, February 26th, 1921) employed Webner's and Meyer's method for controlling erysipelas by injection of novocain and adrenaline into the periphery of the inflamed area in six cases. The injections were carried out with a 1 per cent. solution of novocain, or novocain and adrenaline, subcutaneously or intracutaneously. Nicolas's observations showed that this treatment was not superior to many other methods of dealing with erysipelas. In no case was the spread of the eruption arrested at the injected line, and in no case was the ordinary duration of the disease curtailed. There was also a theoretical objection to the method. Even if the peripheral advance of the erysipelous process had been prevented by the injections, the central area would not be affected, and there was a danger of the streptococci passing into the subcutaneous tissue when their advance in the cutis was held up. Nicolas concludes that the attempt to control erysipelas by injections of anaesthetics is unsuccessful.

622. The Relationship between Lethargic Encephalitis and Epidemic Hiccough.

LEMOINE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 17th, 1921) remarks that several writers have drawn attention to the etiological relationship which appears to exist between lethargic encephalitis and epidemic hiccough. Economo in particular has recorded that the last epidemic of hiccough observed by him in Austria was followed in about a month's time by the appearance of myoclonic encephalitis in the same district. Similar cases were seen by other observers in the Tyrol and Italy. Lemoine himself reports the case of a man suffering from epidemic hiccough, whose brother, with whom he had been in close contact four days after the onset, developed lethargic encephalitis five days later. The close relationship between the two affections is also illustrated by DARGEIN and PLAZY (*Ibid.*), who report a case of a man, aged 42, in whom a prolonged attack of febrile hiccough was followed by typical lethargic encephalitis.

623. The Prognosis and Sequelae of Lethargic Encephalitis.

CRUCHET (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 17th, 1921) records the outcome of 32 cases observed by him from March, 1918, to February, 1921; 13 of these belonged to the bulbo-pontine form, 8 to the meningo-encephalitic, 7 to the mental, 2 to the convulsive, and 1 each to the hemiplegic and spinal forms. Twelve cases, or 37.5 per cent., were fatal, and of the remaining 20 the great majority developed symptoms resembling paralysis agitans, myoclonic movements, or mental symptoms. Cruchet concludes that though as regards life recovery is relatively frequent, the occurrence of grave sequelae should warrant a guarded prognosis.

624. Chlorine as a Therapeutic Agent.

HALLDORSON (*Therapeutic Gazette*, March 15th, 1921) considers that chlorine in watery solution is most useful in the treatment of diseases of the respiratory tract and lungs in children and adults alike. To give the best results the solution must be properly prepared, and, when large quantities are required, it may be made by charging distilled water from gas cylinders. Small quantities of the solution may be made by placing 40 grains of freshly ground sodium chlorate in a quart glass-stoppered bottle, adding acid. hydrochlor. ziff , and allowing it to stand for a minute or two until the salt is dissolved. After adding an ounce of water and shaking vigorously, water may be added in small quantities, with alternate shakings, up to 16 ounces. Care must be taken that the chemicals combine properly, or the solution will contain free hydro-

chloric acid. Chlorine solution may be given in doses of two to four teaspoonfuls in a tumbler of milk in acute tuberculosis, or with some vehicle as "palatol" in pneumonia and influenza; the effect is purely systemic, the solution apparently acting as a neutralizer of toxins.

SURGERY.

625. Hypertrophic Stenosis of the Pylorus.

RAMSAY (*Brit. Journ. of Surgery*, April, 1921) considers that Rammstedt's operation is the operation of choice in the treatment of hypertrophic stenosis of the pylorus. Medical treatment should be given a trial first, but it should not be prolonged if the vomiting is not controlled and weight is not gained, the time spent in such treatment being determined for each individual case. Surgical treatment is also indicated when the infant is so wasted and exhausted that any further loss of weight would be likely to cause death should an operation be performed later. Rammstedt's operation consists in dividing the hypertrophied muscular coat in the axis of the pyloric canal, leaving the mucous membrane intact, and without using sutures to close the gap. Through an incision 1½ in. long, extending downwards from the ensiform cartilage, the pylorus only is brought out of the wound, and is incised longitudinally on its anterior surface in the relatively bloodless area lying between the terminal branches of the vessels running along its upper and lower borders. The whole of the hypertrophied muscle layer is divided without wounding the mucous membrane which bulges freely into the gap, and the patency of the canal can be tested by gently squeezing the stomach. After-treatment consists in feeding and overcoming the marasmus, one drachm feeds of malted milk being given every quarter of an hour as soon as the effects of the anaesthetic have passed off. The quantity and quality are gradually increased according to progress, care being taken to avoid overfeeding or sudden increase. Should any recurrence of symptoms occur and continue, a second operation should not be delayed, since such recurrence probably indicates that the constricting muscular band has been insufficiently divided.

626. Congenital Atresia and Occlusion of the Choanae.

MOURET and CAZEJUST (*Rev. de l'ur., d'otol. et de rhinol.*, March 15th and 31st, 1921) state that although this condition is fairly uncommon it is liable to be mistaken for adenoids by practitioners who are not specialists. In the adult the symptoms and signs are as follows: The complexion is pale, the mouth is half open, the teeth unsound and badly implanted, the upper lip thin and the lower lip dependent. The face is bloated and the naso-labial folds obliterated. The eyeballs are slightly prominent. The nose is thin and sharp. The nasal orifices are narrow and the entrance of the vestibule shows the presence of characteristic thick gelatinous mucus resembling the contents of mucous polypi. The voice is more or less nasal. There is loss or diminution of the sense of taste. The patient complains of a constant dryness of the mouth and throat. Occasionally there is some deafness, which is usually due to chronic middle-ear catarrh. Sleep is often disturbed by nightmares. There is a liability to violent headache, which is probably due to reflex causes or to congestion of the meninges. In the infant the symptoms vary according as the occlusion is bilateral and complete or bilateral and incomplete or only unilateral. In cases of bilateral occlusion the symptoms are very grave. If the child does not die immediately after birth, death takes place very rapidly, as it can neither breathe nor suck. In cases of incomplete occlusion the symptoms are less severe. The cyanosis and recession, which vary according to the degree of nasal permeability, increase during feeding. The child has occasional fits of suffocation and is restless in its sleep. There is more or less rapid emaciation, and sooner or later death occurs. Occlusion of the choanae must be distinguished from adenoids, enlarged turbinates, deviation of the septum, polypi, and foreign bodies, and in infants from stridulous laryngitis. Treatment is exclusively surgical, and consists in making the nasal passages as permeable as possible.

627. Paravertebral Dullness in Carcinoma of the Oesophagus.

LUGER (*Wien. klin. Woch.*, February 24th, 1921), while examining a case of carcinoma of the oesophagus, noticed on careful percussion, a bilateral area of dullness on either side of the vertebral column, which became more extensive as the disease advanced. This finding was confirmed by

subsequent examination of other cases of carcinoma of the oesophagus, and he now records thirteen examples of this disease in which a bilateral symmetrical or asymmetrical area of dullness of varying degree was found on either side of the vertebral column, corresponding to the position of the tumour. The dullness usually disappeared in the knee-elbow position, and sometimes when the patient bent forwards. Luger points out that this percussion sign can hardly be regarded as of great diagnostic significance, as carcinoma of the oesophagus can be detected early by clinical and x-ray examination, whereas this dullness is a relatively late phenomenon. Further observations, however, are required to determine whether the sign is present in deep-seated tumours of the cardiac end which require to be distinguished from spastic conditions of the oesophagus.

628. Death from Nitrous Oxide-Oxygen Anaesthesia.

BALDWIN (*Med. Record*, February 12th, 1921) calls attention to the fact that nitrous oxide-oxygen anaesthesia is not as safe as is generally thought, the death rate in Columbus being 1 per cent. of administrations for major operations, so that its use has been abandoned. Death usually takes place suddenly and without the slightest warning. From experiments carried out by Jackson upon dogs it is concluded that the cause of death in these cases may be either from central respiratory depression, excessive cardiac inhibition, or ventricular fibrillation, and, while it is possible that in all cases each of these conditions is present, one or other of them predominates and is the determining factor, the character of the death varying accordingly. Further special study is urged in order to be able to guard against this danger, or lead to the abandonment of the anaesthetic if the dangers cannot be overcome.

629. The Limitations of X-Ray Treatment in Tuberculous Adenitis.

REYN (*Hospitalstidende*, March 2nd, 1921), who is one of the chief medical officers of the Finsen Institute in Copenhagen, confesses to disappointment with regard to the action of the x rays on tuberculous glands. In the course of treating several hundred cases with the x rays he has rung the changes in the technique, first using unfiltered rays and later adopting different methods of filtration. Tuberculous glands may, indeed, shrink under this treatment, but they often fail to return to normal, whereas when this treatment is supplemented by artificial light the results are infinitely better. This combination of x rays and light baths—carbon-arc lamp or quartz-mercury lamp—is undoubtedly the best treatment available, only excepting those cases in which a single, freely movable, gland can be excised. When tuberculous adenitis is complicated by abscesses and fistulae the combined treatment referred to should be supplemented by local Finsen treatment. The author enforces his indictment of the x rays by reference to a case in which partial arrest of growth of one half of the lower jaw in a child suffering from lupus was attributed to the inhibitory action of the x rays. As a result of deep x-ray treatment the author anticipates many such discomfiting surprises in cases showing no immediate reaction.

630. Congenital Torticollis.

MEYERDING (*Journ. Orthopaed. Surg.*, March, 1921) considers the etiology, diagnosis, and treatment of congenital torticollis. This condition is characterized by a painless, cord-like contraction of the sterno-mastoid muscle resulting from trauma at or preceding birth, the head being drawn towards the affected side with the chin pointing in the opposite direction, eventually producing scoliosis of the cervical spine with compensatory scoliosis in the dorso-lumbar region. Distortion of the face may result, and the muscles, fasciae, and even the vertebrae, may become deformed if the condition remains unrelieved. The painless contraction, easily felt and not tender, and not accompanied by fever, producing the characteristic deformity soon after birth, differentiates the condition from tuberculous disease of the cervical spine. Treatment is essentially surgical, all contracted structures being divided, the deformity over-corrected, and the new position maintained by means of plaster casts. Subcutaneous tenotomy is to be avoided, the contracted structures being freely exposed and divided through an incision just above and parallel to the sternal end of the clavicle. Fixation in a position of over-correction is necessary for from one to three months, according to the degree of the deformity to be overcome, and in order to prevent the possibility of any tendency for the scar to reproduce the deformity by

contracting. In all cases a window should be left over the trachea. Treatment should be undertaken as early as possible in order to prevent the deformity becoming permanent.

631. Permanganate of Silver in the Treatment of Urinary Disease.

GALLOIS (*Bull. Soc. de Thér.*, March 9th, 1921) draws attention to the greater efficacy of permanganate of silver as compared with the potassium salt in the treatment of urinary disease. The doses used were 0.05 gram or 0.10 gram per litre for gonorrhoea and cystitis. The only disadvantage of permanganate of silver is that it is slightly more caustic than permanganate of potash. The pain, however, is not very persistent and lasts only a few minutes.

OBSTETRICS AND GYNAECOLOGY.

632. Placental Retention.

ACCORDING to VERMELIN (*Revue Méd. de l'Est*, March, 1921) the pathogenesis of retention of a placental cotyledon, when not due to unskilful delivery, may be traced (1) to irregular or insufficient uterine contractions, (2) to local abnormalities of the uterine mucosa, or (3) to placental changes, localized or general, of which fibrous induration and diffuse syphilitic softening are those most frequently encountered. Retention should be suspected in those cases particularly in which the third stage has been protracted and accompanied by excessive haemorrhage, and in which the maternal surface of the placenta is unduly rough and exhibits deep sulci between the cotyledons. In a certain number of cases the most skilled observer may remain in doubt as to whether retention has occurred. A cotyledon retained in the region of the uterine cornu leads to marked thinning of the myometrium (for example, to 1 mm. only) at the region of implantation; a cotyledon retained in the lower uterine segment becomes pediculated, presenting in a widely dilated os externum; retention of a cotyledon in the intermediate zone is followed by sub-involution with persistent slight dilatation of the os. The eventual sequelae may consist in (1) spontaneous expulsion; (2) infection—uterine, pelvic, or general; (3) retention with little or no infection, but grave and protracted haemorrhages; (4) in rare instances the occurrence of chorio-epithelioma malignum. With regard to treatment, Vermelin recommends manual exploration of the uterus and removal of the retained cotyledon in cases which are seen immediately after or within a few hours of labour. When the medical man is called to the case some days after labour, a digital examination, preceded if necessary by dilatation of the cervix by means of a tent or Hegar's instruments, and accompanied by a bacteriological test, should be made; where such a test shows the presence of a streptococcus, particularly a haemolytic streptococcus, the author holds that curettage and even digital tearing through the protective leucocyte barrier are equally contraindicated—recourse should be had to hysterectomy. In non-streptococcal cases of prolonged placental retention curettage should be conducted with special care on account of the possibility of extreme attenuation of the uterine wall.

633. Pregnancy and Cardiac Insufficiency.

ACCORDING to AZA (*Medicina Ibera*, No. 178, 1921), while pregnancy in itself cannot lead to cardiac insufficiency, it may aggravate pre-existing cardiac affections, or in cases of morbid conditions caused by gestation may cause such affections to occur *de novo*. Pre-existing cardiac affections may be aggravated indirectly by the increased work demanded of the heart, or directly by elevation of the diaphragm and pressure of the stomach against the heart. The added cardiac impairment may be brought about gradually during pregnancy or suddenly by the strain of labour; in labour may also be produced a cardiac embolus, which is to be distinguished from the septic emboli associated with thrombo-phlebitis in the puerperium. Sudden death occurring *post partum* may be due in certain cases to the increased filling of the thoracic veins which follows the descent of the diaphragm. A case is related of syncope occurring early in the fourth labour of a subject of mitral insufficiency; the vascular conditions contraindicated treatment by pituitary extract and *accouchement forcé* in the patient's state was not possible. Delivery was obtained by vaginal Caesarean section; the post-operative course was normal.

Glaxo is standardised

This fact alone would be sufficient to distinguish Glaxo from ordinary dried milk. Glaxo (Full-Cream) always contains over 25% butter fat and added lactose. The analyses of Glaxo Three-Quarter-Cream (sweetened) and Glaxo Half-Cream (sweetened) are also given below.

STANDARDISED DRIED MILK

Full-Cream :: *Three-Quarter-Cream* :: *Half-Cream*

A Defence of the Thesis

THAT

"THE OPPORTUNITIES OF THE GENERAL PRACTITIONER ARE ESSENTIAL FOR THE INVESTIGATION OF DISEASE AND THE PROGRESS OF MEDICINE."*

BY

SIR JAMES MACKENZIE, M.D., F.R.C.P.,
LL.D., F.R.S.

CONSULTING PHYSICIAN TO THE KING IN SCOTLAND DIRECTOR OF THE
ST ANDREWS INSTITUTE OF CLINICAL RESEARCH CONSULTING
PHYSICIAN TO THE LONDON HOSPITAL

Introduction

My object is to demonstrate that the conception of medical research which is dominant to-day is so immature and imperfect that it renders fruitless much of the research work. Indeed, so imperfect is the conception that fields essential to medical progress are not recognized. It is well, therefore, that men engaged in medical research should at intervals pause and consider what they are doing, so that they clearly realize the object of their endeavour and be certain that their methods are suited to their purpose. Never in the history of medicine has there been such activity as now, and there never was a time when it was more necessary to have a clear perception of aims and methods, especially as great schemes are being launched in legislation in research, and in education. If these schemes be based upon immature experience and imperfect knowledge, the progress of medicine may be hampered for generations.

We are all the creatures of circumstance, and our ideas are moulded by our experiences. Those employed in the study of medicine look at the subject in the light of their own experiences. As the subject is so large, one individual can have an experience of but a small part, so that there is no one capable of seeing it as a whole. The result is that medicine has to be studied in sections, and this leads to specialism. The authorities who guide and direct the progress of medicine are therefore met with but a limited experience, and this leads to a limited outlook. In an attempt to bring together a body of men whose united experience, it might be thought, would cover the whole field, there is a danger that some section may be wanting, and thus a distorted view or a view lacking in perspective may be obtained.

A review of medical progress reveals the fact that medicine is emerging, slowly and hesitatingly, from a past burdened by tradition and even superstition. The conception of what constitutes medical science is still so imperfect that no clear understanding exists on what lines it should be pursued. While the aim of medicine may be recognized, the methods by which this aim may be achieved are not yet understood, and this lack of understanding is leading medicine astray.

In dealing with the clinical aspects of research, and particularly with the opportunities of the general practitioner, I must dwell upon the limitations of laboratory methods, and I may seem to belittle their importance. This is far from my intention. No one recognizes the importance of laboratory methods more than I do, and probably no clinical observer has received greater help from them. Indeed, I consider that I have a better appreciation of their methods than many who indiscriminately belaud them. My experience not only enables me to appreciate their value, but also to recognize their limitations.

Successful Methods in Research.

Let us briefly look at one aspect of the subject by considering where medical research has been successful. The highest aim of all research is the prevention of disease. If we take the instances where this aim has been achieved we find a uniform method of procedure. In every case the clinical observer, by the exercise of his peculiar methods, took the first step. He recognized in the sick man the signs of disease, he differentiated these signs in such a manner that he was able to recognize

separate forms of disease. He recognized these signs at such an early period that he detected the circumstances that favoured or induced the disease. He was then able to take steps to prevent the disease. Such is the history of the prevention of such diseases as typhoid fever, syphilis, rabies. At other times he has not been able to carry the investigation so far, and recognizing his limitations he handed the subject over to the laboratory worker, as in malaria and allied diseases.

Such in brief is the method which common sense tells us should be followed in the case of every disease, but where is the clinical observer to be found to-day?

A foolish idea has arisen that the methods by which he made his contributions to research are so easily understood that they need little consideration, and so easily recognized that they need no special investigation, and that their possibilities are exhausted. There never was a greater fallacy. We know that it takes many years before a man becomes trained in bacteriological technique. It requires a much longer time to train a man to recognize the early symptoms of disease. It takes many years of experience to put intelligent questions to the patient, and more years of experience to enable the replies to be interpreted.

The part which the clinical observer should play in medical research is to-day not recognized, and there follows as a consequence an insurmountable obstacle to attaining the chief aim in medicine—the prevention of disease. If you do not recognize the early symptoms of disease you can never recognize the circumstances that favour or cause its onset. This to me is such plain common sense, that it is one continual source of wonder that our authorities fail to see it.

Once this is seen, the next question is, Who is the man that has the opportunity for seeing the early stages of disease, and the circumstances that favour its onset? There is only one person, and that is the general practitioner.

The Diseases Common among the People.

When we started our enterprise at St Andrews, we reflected that if success were to attend our efforts we must clearly perceive what we were aiming at. Our chief aim was the prevention of diseases which are common among the people of the country.

The question arose "What are those diseases?" Seeing that we have now a Ministry of Health one would naturally expect that this knowledge would be in its possession. Seeing also that doctors are being educated to combat these diseases, it might have been expected that educational authorities would know. But a brief inquiry revealed the fact that this knowledge does not exist.

The reason for the absence of a knowledge so essential to intelligent law making, education, and research, is that it can only be obtained by the general practitioner, and no one ever thinks of asking him to undertake any inquiry.

We therefore started an inquiry into this matter, and met unexpected difficulties. However, we got an insight into the matter that revealed defects in medical knowledge so great that they more than justified our undertaking.

One fact that came out clearly was that the impression that great progress had been made in recent years was scarcely justified, so far as the recognition and prevention of disease was concerned. We found that discoveries of the origins of common diseases were so few during the past fifty years that we had difficulty in recognizing any advance. A little consideration revealed the reason.

The Progress of Medicine during the Past Century

A hundred years ago we can trace medicine following two distinct paths. There was the clinical school, mainly British, in which the chief instrument was the clinical observer with his trained senses and his mind stored with the fruits of his past experience. There was the growing laboratory school, mainly Continental in its origin, which received a great impetus when Virchow introduced the theory of cellular pathology. Up to fifty years ago the trained observer was slowly unravelling the early symptoms of disease, discovering the beginnings of disease and their cause. With the increase of knowledge of the structure of the body and of the modifications produced by disease, and by improved laboratory technique, pathology gradually came into prominence. The dead house became the centre of great activity. The accurate observation of diseased organs revealed on the *post mortem* table led the

* Being a lecture delivered at St Mary's Hospital in the Institute of Pathology and Research during the course on Pathological Research in its Relation to Medicine.

physician to seek in the living the evidences of these diseased organs, and thus was laid the foundations of that physical diagnosis which we know to-day. The seeming sufficiency of this method of study led to a classification of disease based upon the morbid appearances of the organs, a classification which survives and influences teaching to-day.

There is a delusive precision in this classification which has had a pernicious effect on medicine as a whole. It may be true of disease as seen from the dead-house point of view; it may be partly true of disease as seen from the point of view of the medical and surgical wards, but it is so little true as to be misleading when looked at from the point of view of the general practitioner. It is misleading because it deals only with end-results, a totally different matter from the early stages of disease. These end-results may be the diseases imposed upon a constitution already enfeebled, or the outcome of a process whose symptoms in the early stages have never been recognized. One outcome of this classification has been to rivet the search on those signs which occur only in advanced states of disease—when, that is to say, damaged tissues produce a physical sign. So powerful has this influence been that attention is now concentrated on the search for improved methods by which these physical signs can be revealed. So many methods have been discovered that men have to devote themselves to special branches, and we see the result in the specialism of to-day. It seems not to have been grasped that the specialist can only recognize disease after it has gone so far as to damage the organs, and no specialist ever sees the early stages of the disease in which he specializes.

Following upon the introduction of more accurate pathological investigation came the microbic theory of disease, with its startling revelations and successes. The imagination of the medical world was fired, and the most exaggerated expectations were formed of what it could do, and thus it practically superseded all other methods of investigation, and speedily attained that dominant position which it holds to-day. Following in its track came the introduction of the methods of other sciences, and there arose that conception of medicine which looks to the laboratory as the only sphere of progress. As a result the methods of the clinical observer by which so much had been achieved fell to the background, and as an investigator he gradually disappeared. This was a calamity, and the more so that neither the part he should play or the opportunities which he possesses are understood.

Movements in Circles.

Between the town of Burnley and the village of Haworth, where Charlotte Brontë lived, there stretches a wide moor. Some of my friends started one day to walk from Burnley to Haworth. About an hour after they started a heavy mist fell and they lost their way. They happened on a shepherd's cottage and the shepherd gave them their directions. In three hours they were back again at the cottage, having wandered in a circle. This well-known tendency to walk in a circle is a human peculiarity that affects not only bodily movements but mental. History shows civilizations that arise, make a little progress, then make no further progress, but move round and round and gradually relapse. Religions, too, can show the same process. This kind of arrested development affects individuals, for we all know how many young men start out in life with every prospect of going far, and after middle age are found muttering the shibboleths of their youth.

There are signs that this tendency hampers medical progress, and much of what we assume to be progress is but moving in a circle, and results which are taken as signs of progress often but add to the fog which obscures the way.

Prognosis.

I do not develop this theme to-day, but my purpose is to direct your attention to a subject which illustrates this point of view. I choose one with which you all are familiar—indeed many may think it so well known that it needs no consideration. It is, moreover, a subject which acts as a guide to progress, a beacon in the fog, and at the same time provides the means by which progress or the reverse can be judged. Moreover, it is a subject of the very first importance to the intelligent practice of medicine;

but I do not know how to present it in a manner that will convey to you its significance so as to carry conviction.

When a true insight is obtained into what medical science means it will be found that the great obstacle to progress is a lack of understanding of prognosis. Up to thirty or forty years ago the subject was making progress slowly and crudely but definitely. During the last quarter of a century it has got such a set-back that to-day its importance is not understood, the principle which should guide to its knowledge is not appreciated, and the individual whose opportunities afford the means of acquiring this knowledge is not recognized.

I have repeatedly discussed this matter with various authorities in different departments of medicine, and nowhere can I get anyone to appreciate its real nature. The newly qualified doctor is as oblivious to its importance as the matured physician who has for twenty or thirty years been engaged in life insurance examinations, in which it is currently assumed that a prognosis is necessary.

If one wanted evidence of the complete misconception of this subject, it is the practice of appointing laboratory trained men to teach clinical medicine, and the assumption that as soon as a man is qualified he is capable to examine recruits for the army and navy and candidates for life insurance. If I can get you to understand the meaning of prognosis, the futility of these procedures will be apparent to you.

The Importance of Prognosis.

In medical practice one question arises incessantly and persistently, implied or expressly demanded of the doctor, and that question is, "What is to be the outcome of my complaint?" The patient or his friends want to know if the illness is temporary or is it to result in ill health or in death. Then other questions arise, Are there remedies for this complaint, and what are they?

To answer these questions requires a knowledge of prognosis, and one of the cherished beliefs of the public is that doctors possess that knowledge. Moreover, common sense tells us that the public is perfectly justified in expecting from the doctor a knowledge so manifestly essential to the intelligent practice of medicine.

The Peasant and Prognosis.

I was presenting these views once to a very capable general practitioner who had had a distinguished university career. He cordially agreed, and described an incident which forced on him the importance of prognosis, when he entered upon practice. A few days after starting as an assistant to a general practitioner he was called to see a sick ploughman. He examined him and diagnosed a pleurisy. Pleased with his diagnosis, he, in learned fashion, informed the man's wife. She replied, "Aye, but when is my man to be fit for his work?" My friend was taken aback—during the whole of his education he had never been taught to realize that such a question should be asked, and he could not himself answer what he recognized to be a most natural question. I have little hesitation in saying that this poor peasant woman had instinctively a better realization of the requirements of medical practice than the authorities to-day who direct medical education and research.

Let me give some instances illustrating this peculiar defect in medical knowledge.

Recruiting and Prognosis.

Of the vast importance of the subject of the disastrous effects of a lack of . . . of the disastrous effects of a lack of . . . subject we have had during the war striking evidence. When at a time of great national stress a call was made for men to join the army, it was assumed by the nation, as well as by the military medical authorities, that there existed sufficient knowledge to separate the fit from the unfit. This was really a test on the greatest scale of the adequacy of medical knowledge. At the outset the knowledge was found wanting, for large numbers of perfectly healthy men were rejected, because they presented signs whose value the medical examiners were unable to assess. Later, when the national strain became greater, and it was necessary that even those with impaired health should enter military service, the military authorities again thought they possessed the knowledge necessary to say what amount of physical effort a man was fitted for. It is unnecessary to dwell upon the complete

failure that resulted. So glaring were the mistakes, so unjust were the decisions, that the whole nation was aroused and Parliament was forced to intervene. If there was ever a need for inquiry, here was one; yet the whole matter is brushed aside as if it had never occurred, and medicine has fallen back into its old ways. This illustration shows how backward is the state of medicine when the authorities who direct it are incapable of realizing a defect even when their best endeavours end in a miserable failure.

Prognosis in Surgical Practice.

Another aspect of the subject is shown in surgical practice. If we take a common complaint like appendicitis, there are certain signs which are held to indicate the presence of this disease. The question arises whether these signs indicate a condition which will endanger the patient's life. In other words, what is the prognostic significance of the signs? The question is one of prime importance to the patient, for it may be a matter of saving his life if the danger is recognized and removed; on the other hand, it may be putting the patient in danger by an unnecessary operation—danger to life or of permanent damage to his health.

Many a patient has had his appendix removed when there was nothing the matter with it. Everyone recognizes that appendicitis does occur, and, if not operated on, death may result. The attitude of the surgeon to-day is that, seeing that there is danger, and seeing that surgical knowledge cannot discriminate between the cases where there is danger and those where there is no danger, it is safer to operate. It is the same in the surgical treatment of gastric ulcer. I have seen patients greatly benefited by the operation; I have seen some made worse by the operation, and I have seen patients die in consequence of the operation. These results are due to an absence of a knowledge of prognosis.

Prognosis and Vaccine Therapy.

The development of the bacteriological branch of medicine has resulted in the introduction of new forms of treatment by serums and vaccines. When a person is ill, and a microbe is the suspected cause, the appropriate treatment is to combat this microbe by a vaccine. But here arises the question, Is the patient likely to recover without treatment? If so, then the treatment is unnecessary. If the patient is in danger of death, wherein lies the danger—is it due to that microbe or to other complications?

This is not quibbling, but is essential to intelligent treatment. For instance, I have heard it seriously proposed to find the microbe of measles, and then to get a vaccine to give to patients afflicted with measles, because many people are supposed to die of measles. But the question arises, Do they die of measles? During my twenty-eight years in practice I saw numerous epidemics of measles, and only two patients died; but these did not die of measles but of complications—laryngitis and bronchopneumonia—brought on through injudicious exposure. If due care be taken, why give the vaccine? Unless the source of danger is recognized and provided against, the treatment by vaccines becomes rule of thumb, and is but a reversion to the empiricism of bygone times.

If treatment is to be intelligent, or even scientific, a prognosis is absolutely essential, yet in some recent textbooks on surgery and vaccine therapy I do not find the w mentioned.

Prognosis in Treatment by Digitalis.

Did time permit I could illustrate in many ways how essential prognosis is to scientific treatment. Let me give one example. For more than one hundred years it has been recognized that digitalis had a beneficial action in certain forms of heart disease, but no definite knowledge existed as to the kind of heart disease which benefited, so that every person supposed to have a heart affection was given digitalis. Careful investigation has revealed that the drug is of use in only a small percentage of cases, and that of a particular kind. We can now recognize with fair certainty the cases where it will have a good effect and those cases in which it is of no use.

The recognition of the cases that are benefited by digitalis saves us from giving it to those cases in which

it is of no use. Thus, instead of an unintelligent rule of thumb treatment, we study the peculiarities of each individual case in order to find the treatment appropriate to his condition. The manner in which this knowledge was acquired will be described later.

The Investigation of Prognosis.

It will perhaps help to get a clear idea of what I am aiming at if I describe the steps I took to obtain this knowledge in affections of the heart.

On entering general practice my knowledge was much that of the young doctor of to-day, except that perhaps we were better taught in regard to this subject. I was not long in finding out that my knowledge was limited. As an examiner for life insurance I realized that I had no real knowledge of the prospects of a candidate's life. In dealing with my patients I would put people on treatment and restrict their work because of some vague notion that murmurs and irregular action indicated something seriously wrong. The textbooks, to which I appealed again and again, though reputed to deal with prognosis, afforded no help. Recognizing the limitation of my knowledge, I determined to see if it was possible for this knowledge to be acquired.

I saw at once that it would be necessary to watch individuals with what I considered damaged hearts for the rest of their lives to see what happened, and I started to do so. But the question soon arose, What was I to watch? I spent a long time noting with great particularity the murmurs and modified sounds, and the rate of the heart when at rest and on effort. But the results were so unilluminating that I found I was getting no further. I got a sphygmograph and took records of the pulse, and spent much time measuring the height and breadth of the waves, the depth of the notches, seeking in these signs for light upon the subject of prognosis.

In efforts of this kind I spent several years, and felt inclined to give up in despair. My experience at this stage may be of some service to others who undertake similar forms of medical research. Pausing to reflect, I was struck with the resemblance of myself to one of the characters depicted by Bunyan in his *Pilgrim's Progress*. He describes a man earnestly engaged in raking the mud in search for something he was not quite clear about, while above his head shines the crown of glory which was the real object of his research. I felt like the man with the "muck-rake," and I felt certain if he were addressed in modern terms the conversation would be somewhat as follows. If asked what he was doing, he would reply he was collecting stones and twigs and straws. If it was suggested that this seemed a vain quest, he would reply that he was discovering new facts, and as a new fact was an addition to the sum of human knowledge, the quest was therefore justified. Moreover, he might add: I am the first to introduce scientific methods in this research, as I weigh the pebbles and measure the straws.

Rules for the Investigation of Symptoms.

I saw that I must have some clearer guide in my work. I reflected that I had to deal with people in ill health, and the nature of their ill health could only be discovered by understanding the symptoms of disease. The physicians of thirty or forty years ago were, many of them, very capable men. Their minds were not distracted by the numerous methods which to-day are considered necessary for the examination of their patients, so that they cultivated their powers of observation. I had been struck during my student days, and later when I entered practice, by the rapidity and precision of diagnosis, in patients who presented no physical sign, and the assurance with which they would foretell whether an illness would pursue a favourable or unfavourable course. The old doctor to whom I was assistant possessed this faculty in an eminent degree, and I often to-day reflect with admiration on the remarkable certainty of his diagnosis and prognosis. When I was considering my failure to get forward with my investigation I reflected on these matters, and I saw that this knowledge was due to the recognition of subtle signs which could only be detected and appreciated from long and careful observation. The knowledge was personal, and medicine had not advanced so far as to enable a description to be given which would convey the knowledge to others.

Seeing that disease makes itself manifest only by the symptoms it produces, I recognized that the first step in my undertaking would be to acquire a better knowledge of symptoms. In order that my inquiry should be directed in a systematic manner, I laid down three rules for guidance.

1. To differentiate each symptom clearly, and separate it from others it might resemble.
2. To discover the mechanism by which each symptom was produced, and to search for the laws governing the production of symptoms.
3. To assess the value of the symptom, so far as it had a bearing on the patient's future—the prognostic significance of the symptom.

By following these rules I hoped to get an insight into the nature of the diseases of my patients, and to find out the explanation of the older physician's power of diagnosis and prognosis. This was all the more necessary since the vast majority of my patients had no gross physical sign of disease, the symptoms being mainly subjective, or of such a subtle and elusive kind as could only be detected by the trained senses.

Except incidentally, I do not propose to refer to the steps I took to differentiate the symptoms and to understand their mechanism, but I propose to describe at some length how I proceeded to investigate their prognostic significance. This subject has been neglected because those engaged in research do not have its importance thrust upon them. On the other hand, experience had shown me that for intelligent practice this matter was essential, and that these two other fields were but preparatory for this, which is indeed the coping stone of all medical investigation.

As time has gone on I find that the conception of prognosis grew upon me till I now recognize it as the vital spark which endows medical investigation with life and interest, and that what rendered so much endeavour vain and futile was the absence of this life-giving conception. So far no one seems to have realized that this important field was necessary to the completion of all research in medicine.

Prognosis in Heart Affections.

Guided by these rules, I continued the study of affections of the heart. The methods necessary to differentiate symptoms and study their mechanism were comparatively easy to discover, but it was a long time before it became clear how to proceed with the inquiry into prognosis. At last I put to myself the question, "What are you afraid of?" The reply was "Heart failure." The next question then arose, "What is heart failure, and what are the symptoms by which it can be recognized?"

Were murmurs and irregularities signs of heart failure? I had to confess that, except in certain forms of heart failure where dropsy and dyspnoea occurred, I had no idea of the signs of heart failure. Again I turned to my textbooks—clinical, physiological, and pathological—for a description of the signs of heart failure, and again discovered that the knowledge did not exist. I recognized that until I knew the signs of heart failure I was incompetent to study the prognostic significance of heart affections. So I set about to acquire this knowledge and spent years in the quest. Though far from completed, I gained knowledge sufficient to enable me to recognize the importance of the subject and how it should be investigated.

Let me explain how this was done. I had first to watch, in people with failing hearts, the appearance of symptoms, and re-educate myself in the examination of the patient so as to differentiate the symptoms clearly.

This, to a certain extent, had been done in regard to murmurs and modified sounds, but the equally common symptom of irregularity had been neglected. After many years I was able to differentiate the irregularities. I had also to study with care the sensations of the patient, for, as I ultimately found, this was the key which brought the solution of the problem. I thus found out the sensations that indicated heart failure. I found, among other things, that the first signs of heart failure were not to be detected in the heart itself, but were shown in the disturbed function of organs remote from the heart. Then I had to see people before the heart was affected; I had to watch the circumstances that weakened the heart; I had to see the effects of hard work, of pregnancy, of intercurrent diseases,

and I had to detect the onset of the earliest sign and watch the progress till death. I had to find out the mechanism by which the various symptoms were produced, and to do this I had frequently to resort to the physiologist for help. By the knowledge thus acquired I was able to distinguish those signs which were of significance from those which were of no significance. It will be seen that to understand the subject of prognosis the observer has first to undertake a long training, and then he has to have the opportunity of studying not only acute cases, but cases that proceed gradually for ten or twenty years or longer.

It is impossible for those who have not undertaken this kind of research to understand its difficulties. Let me describe one phase of the subject. One object I had in mind was to understand where lay the danger of pregnancy in a woman with a damaged heart. This is a problem which confronts, time and again, every general practitioner, and it is one of very serious moment to those concerned. The references to this subject in the most recent books on obstetrics have not advanced beyond those published over forty years ago. To undertake this part of the inquiry I had, as I have said, first to train myself to detect the early signs of heart failure. Then I had to study the changes in the circulation and search for the causes producing them, during pregnancy, during confinement, and during the puerperium which occurred in healthy women; I had to watch the changes that took place in women with different forms of heart disease, examining them before pregnancy and at all the subsequent stages. This meant attending them during labour, taking careful observations during the pains and when free from the pains. These observations were not made in a comfortable ward with plenty of help, but often after a hard day's work, during the night in poor cottages, where I had to do the duties of the doctor and nurse, give chloroform, apply the forceps. Yet this work had to be done, and in no other way could the knowledge be acquired.

It will be seen that a matter like prognosis, so essential to medical practice, requires methods and opportunities of a particular kind, but so backward is the state of medicine that neither the methods for acquiring this knowledge nor the value of the knowledge when acquired is understood.

Guiding Principles in Prognosis.

It was necessary not only to seize the opportunity and make a note of symptoms, but to have a clear guiding principle. I want you to grasp this point, for it was the want of this principle that caused me to spend years in "muck-raking." I remember examining repeatedly a man suffering from angina pectoris and failing to detect any physical sign of disease, yet he could not walk 200 yards without being pulled up by an excruciating pain. When he died I found the myocardium extremely atrophied and the coronary arteries blocked. I saw that this condition must have been coming on for many years, and this caused me to reflect on the effects of the damaged muscle. When the man was at rest he was quite well, mentally active, and complained of nothing, but when he made an effort he was pulled up. So I dimly conceived that the symptoms were only produced in response to effort. Then I considered the nature of the heart's functions, and recognized that the muscle force of the heart could be considered as being of two kinds, one to maintain the circulation when the body was at rest, and the other a reserve force, called into play when an effort was made. On reflection I recognized that the first sign of heart failure was bound to be a diminution of this reserve force, and that the earliest symptoms of heart failure would be shown in a response to effort.

I therefore made a long investigation into this response to effort, considering first what happened to people in health. In childhood the response to effort is small, for the child stops after running a few yards. In boyhood it is much greater, and reaches its greatest amount in the heyday of youthful vigour; after that it gradually declines till the old man reaches the limits of his childhood. I compared these results with what happened in disease, and found that the response to effort was restricted in exactly the same way. Then I asked, What are the signs of this limitation? And for a time, being under the delusion that instruments were the most scientific method, I spent much time in recording the rate of the heart, and studying the changes in the character of the pulse by graphic records

and blood-pressure instruments. These did not help. Then it occurred to me to ask of the individual, healthy and ailing, "Why have you to stop," and they all replied, "Because of a feeling of distress." This gave a new turn to my inquiry, and I then investigated this sensation of distress. At first it was difficult to get a clear conception, for I was too ignorant to ask the suitable questions and too ignorant to interpret the answer. After a time I got a little understanding, and gradually the nature of the distress became perfectly clear. The reason why I failed, and, indeed, why the medical world fails to-day, to understand the symptoms of heart failure is because of their extreme simplicity. When we search for the recumbent and the obscure we fail to recognize the simple and the obvious.

The sensations of distress which indicate the limitation of the heart's power are of two kinds—breathlessness with its associated phenomena, and pain with its associated phenomena. When you come to think of it, a failing organ does not itself necessarily show its impaired efficiency; rather the symptoms will be shown by the organs which are affected by the diseased organ's failure. Health is the harmonious working of all the organs. The disordered or impaired function of one organ upsets the others, and the signs of ill health are found, not in the inefficient organ, but in the others.

The Estimation of the Functional Efficiency of Organs.

That is a principle which is of universal application, and should be applied to the study of the functional efficiency of every organ.

In regard to the heart, its failure affected structures which did not receive a sufficient supply of pure blood. The respiratory system is the most sensitive, and possesses a mechanism which causes distress when its blood supply is inefficient—so we get breathlessness. The heart muscle, when forced to increased effort, requires more blood, and if it fails to receive an adequate supply it gives expression to its exhaustion by pain, a symptom belonging to the nervous system.

I cannot here explain the steps by which this conclusion was reached, nor show you what a flood of light it has thrown upon that darkest of fields in medicine—the evidences of functional inefficiency of organs. While for many years I have used this knowledge in practice, the full meaning of it was not understood until, in St. Andrews, we had carried the inquiry further, and discovered the mechanism by which such symptoms and the vast majority of other symptoms were produced.

If you reflect, common sense will tell you that the response to effort is the only means by which the efficiency of the heart can be recognized. It is now many years since I called attention to it, yet its significance is not grasped. You can see this failure to grasp it in the medical forms for life insurance. Questions are asked about the size of the heart and its sounds, its rate and its rhythm, but not a single question as to the response to effort. Some companies have an elaborate series of questions for suspected hearts, but in none of these is there any reference to its functional efficiency. People are to-day rejected for life insurance or penalized because of an innocent murmur and irregularity—a mistake which would never occur if insurance examiners understood the response to effort. Other people are passed as fit who would never be accepted if the answer to a simple question was skillfully interpreted. I have on many occasions been consulted by men who had a few months before been insured for large sums, who suffered from such advanced disease of the heart that they died shortly after. There was no physical sign, but their replies to my inquiries as to their response to effort revealed the extreme gravity of their condition.

It requires much experience to use this method, but when the knowledge is acquired it is easy. The testing of a patient by hopping about a room and counting his pulse and taking his blood pressure cannot reveal this information; it is got from the patient's experience when the heart is called upon to do its usual work—such as walking up a hill after a meal, walking in the cold air, and so forth. The reason I mention this is to indicate that artificial tests do not bring out the qualities of an organ, neither in the case of the heart, of the stomach, of the kidney, or of any other organ.

The Misunderstanding of Prognosis.

The lack of understanding of the importance of prognosis comes out in striking and curious ways. A great many people have been engaged in the investigation of irregular heart action, and much of the mechanism has been revealed; but they stop there, being content with the recognition of the different forms of abnormal heart action. To me, on the other hand, this research was but a means to an end, not the end itself—the end being the prognostic significance of the irregularities.

Here is a curious matter. I have received a meed of praise far beyond my deserts for the employment of mechanical methods in general practice. Indeed, I do not doubt that is the reason why I have been honoured to address you to-day, and I have been told that this was the reason I was made F.R.S. That implies a limited outlook upon medicine. The use of these graphic methods was but child's play to the search for the significance of irregular heart action. If you could but grasp what that long search meant—the difficulties to be overcome, the taking up of methods and finding them unfit, the constant study of the patient, the search in literature for all sorts of knowledge that might help—you would realize how heavy was the task and how infinitely more important was the result. And yet, gentlemen, though I have been praised and honoured for the easy task of record-taking, nowhere have I seen any recognition or understanding of what I may say has been the chief object of my life's work.

The Keeping of Records.

Did it ever occur to you why records of patients are kept? Every hospital keeps them as a routine, but it is doubtful if the reasons are understood. The chief purpose of records is to lay the basis of prognosis—that is, to obtain a knowledge of a patient's complaint from data drawn from patients presenting similar symptoms whose progress has been observed. The real purpose of records is to show this progress. They can be used for other purposes, but these are subsidiary. To-day they fail in usefulness because of the absence of a knowledge of prognosis. If you consider the enormous amount of record-taking and record-keeping in all the hospitals and private note-books in the world, with the enormous number of life insurance records, and reflect that if one wished to know what was the significance of some simple sign, such as a heart murmur or irregularity, the information could not be obtained, you will appreciate the futility of record-taking as understood to-day. The records taken to-day are not a bit more helpful than those taken fifty years ago. I know this will be disputed, for there is a belief that medicine has made such gigantic strides that signs and symptoms are now detected that were never before recognized. Thus a physician who has had some laboratory training in biochemistry includes in his notes the chemical constitution of some fluid. Another who has studied the blood will reflect his speciality in his records. If he has studied bacteriology the records will describe the various bacteria found, while blood-pressure records and electro-cardiograms will show the bent of others, and so on. Each one finds his justification in the belief that in recording facts he is adding to the sum of human knowledge, whereas he is but adding to that enormous mass of chaotic details which darkens and confuses medicine to-day.

The Purpose of Records.

The real purpose of record-taking is to relate the life-history of disease in a number of people so that the signs which reveal the disease and show its progress and those which indicate danger can be recognized.

Prognosis is the motive which inspires note-taking with the breath of life, making the notes a perennial source of knowledge that can be applied in the practice of medicine. To obtain records of value, opportunity must be had of seeing disease from its onset till its end, while knowledge of a particular kind is required in order that out of the mass of symptoms those that are essential only are recorded.

While that is the ideal, only those who have recognized it and have striven to attain it understand its difficulties. This ideal, it is to be observed, differs greatly from the practice of to-day when there is too often but a dreary record of undigested symptoms during a passing phase of disease.

The Records of Mitral Stenosis.

In order to convey some idea of the method and purpose of record-taking, let me cite my observations on mitral stenosis. It is over fifty years since the presystolic murmur was recognized as indicating stenosis of the mitral valve. If you turn to most textbooks you will find that since that day no progress has been made in our knowledge of this murmur, or indeed of any other murmur—that is to say, for fifty years auscultation has not progressed, and notwithstanding all the alert minds that have been engaged in clinical medicine, no conception existed as to how progress should be made. But as soon as I was possessed of the idea to find what happens to the individual with a presystolic murmur, new life was breathed into my work, and a way of progress opened up.

Early in my career as a general practitioner I found that the presence of mitral stenosis was associated with danger to pregnant women as well as to others. It was necessary to know wherein lay the danger. To understand this it was necessary to know the life-history of people with this trouble. I therefore began a series of observations on patients with rheumatic fever or who had had rheumatic fever. I kept in contact with them for many years, and watched the progressive changes that took place in the sounds of the heart. In this way I discovered that the murmur peculiar to mitral stenosis—the presystolic—did not occur during the causative attack but at variable times afterwards—usually several years. The murmur at first was short in duration and was not always present. As time went on it became of longer duration and constant. By-and-by another murmur appeared, diastolic in time. This increased in length until it ran into the presystolic, so that during the diastole of the ventricle there was a continuous murmur. When such patients died the mitral orifice was reduced to a mere slit. One infers that the cicatrizing process is gradual, and that these changes in the murmur are due to increase of the cicatrizing process which narrows the orifice. But the point of importance is that you are given an idea of the stage of narrowing that has been reached. Moreover, the rate of progress varies greatly; some only reach a certain stage and remain stationary. The recognition of this gives a further guide to prognosis. It is necessary, for instance, in advising as to a woman's fitness for child-bearing to know whether the stenosis is stationary or advancing rapidly, and this knowledge is obtained by recognizing the peculiar features of the murmur, whether short or long, or whether a diastolic murmur is present, with a knowledge of the time of the causal attack. Thus, a short presystolic murmur with a history of rheumatic fever ten or fifteen years before would indicate a favourable prognosis, while a presystolic and diastolic murmur with a history of four or five years would give a much graver outlook. To-day, amongst obstetric physicians, there is much confusion, for, while one group says mitral stenosis is a very dangerous complication, others declare it not to be of serious significance, the reason being that each speaks of the cases that come within his own experience, none recognizing the principle that should guide them.

But in this inquiry I was struck with the great diversity of phenomena that arose. Thus some patients suffered from severe heart failure and died while yet the stenosis was slight in degree. Others pursued laborious occupations when the stenosis was far advanced. I therefore recognized that there were other factors, the chief of which I found to be a coincident damage to the heart muscle. Sometimes this could be made out by the changes in the size of the heart, or by the presence of partial heart-block, but the most instructive indication was the response to effort. This meant that the mitral stenosis was but one factor in assessing the functional efficiency of the heart, and that it was necessary to consider the associated phenomena and particularly the response to effort.

Many instructive phenomena, which explained features that had puzzled clinical observers (to some of these I will refer later), came under notice during this research. But the most striking and most dramatic was the sudden onset of extreme heart failure that every now and again overtook some of these patients. One, whom I had watched for seventeen years, and who had lived a useful and industrious life as a nurse, was suddenly seized with great breathlessness, and the heart became rapid in its rate and dilated. She was cyanosed, the liver was enlarged, and dropsy set in. On taking graphic records I found that the

rhythm was very irregular and the auricular wave had disappeared from the jugular and liver pulses. On listening to the heart the presystolic murmur, which had been present, had disappeared. Thus all signs of auricular activity had disappeared.

My attention being arrested by these signs I sought for similar conditions and found that these cases were frequent and occurred independent of mitral stenosis, so that I was able to recognize a definite and distinct type among heart cases. Indeed, I found that between 80 and 90 per cent. of cases of heart failure with dropsy and enlarged liver were of this type. I then proceeded to watch these cases to see what happened, and I found that on the onset of this abnormal rhythm the heart failure set in with such severity that some died within a few days, others within a few weeks, others led a crippled existence for months or a few years, while others lived comfortably at a lower level for many years, and in a few the onset was not accompanied by any limitation of the heart power. Seeing these very diverse results I set about a long inquiry into the reasons. I found that in those who did well after the onset, though the heart rhythm became irregular, the rate did not alter. On the other hand, in those who did badly the rate became increased, sometimes greatly. In watching them I found that if the rate slowed the patient improved, so I looked for means for slowing the rate and naturally turned to digitalis. I gave the digitalis at first timidously, as we were brought up to look upon it as a dangerous though useful drug, then more and more boldly, till I found the quantity that would slow the heart. When I had acquired a knowledge of the drug and how to administer it, I was able to give speedily the greatest relief to many patients who were apparently *in extremis*. But I found that as soon as the drug was stopped the patients relapsed, so I set about discovering how to give the drug so as to keep the pulse at a moderate rate, and at last devised a method by which many people who were apparently hopelessly broken down were enabled to resume their occupations.

In some the digitalis or other drugs would not slow the rate, and these invariably drifted and died. In others in whom the heart slowed, the symptoms of heart failure were not relieved—these also speedily sunk and died. The *post-mortem* examination in these cases invariably revealed such extensive damage of the heart muscle that one could infer that such hearts, embarrassed by the abnormal rhythm, were inconsistent with life.

I need not go into the numerous interesting points that arose from this inquiry. One I may mention was that the particular kind of rapid heart for which digitalis is the remedy stood now clearly revealed, as I have already said. If you have grasped the significance of the methods I adopted for getting the prognosis you will at once see what a powerful weapon has been placed in our hands, and with what confidence we are now able to give a clear prognosis based upon accurate observation and sound principles.

Many years after, this condition was discovered from experimental search to be due to fibrillation of the auricle, and it is a curious illustration of the lack of perception of the essentials of medicine that the discovery of this condition is frequently assumed to have occurred only when it was demonstrated in the laboratory. All that work which revealed its clinical symptoms, which laid the basis of a sound prognosis, and which indicated rational lines of treatment, is practically ignored. The research in the laboratory has indeed helped to a partial understanding of the mechanism, and to differentiate this condition from others it resembled, but it has not added one iota to the knowledge necessary to clinical practice. Indeed, so little is the significance of this inquiry realized that in books and articles written by cardiologists you seldom find any appreciation of the basis for a rational treatment, let alone a rational prognosis.

I do not quote this in order to disparage laboratory work or to praise myself, but to demonstrate the blindness to what is essential in medical inquiry—to illustrate the limitations of laboratory investigations into disease states. While we recognize the presence of auricular fibrillation, we do not know the conditions which induce it, nor is there the slightest expectation that laboratory experiment will reveal it. I have a poor woman who suffers from haemorrhages, which occur spontaneously under the skin. It would not throw any light upon

ill health to give a man a black eye. It is vain to expect to discover a process of disease by applying to a healthy organ a stimulus of a kind which nature never employs. A disservice is thus done to experimental work, inasmuch as it is asked to reveal that which it cannot reveal.

New Fields Opened up by the Study of Symptoms.

In watching the life history of patients with mitral stenosis a great number of instructive incidents occurred. By keeping in mind the rules I had adopted of differentiating the symptoms and recognizing their mechanism and their prognostic significance a light was thrown beyond the immediate object of research and opened up other fields of inquiry. There was revealed, for instance, the nature of many functional abnormalities, which could not be shown by experiment or by the study of dead organs. Thus one man whom I attended for rheumatic fever in 1880 was left with a damaged heart and a systolic murmur. It was ten years later before I detected a presystolic murmur. Later I recognized that this murmur became separated from the first sound by a short pause—a feature which had been described as a mid diastolic murmur. Records of the jugular pulse showed that at the time of this mid diastolic murmur there was a wave in the jugular vein due to the contraction of the right auricle, and there was an increase in the interval after the wave before the carotid pulse appeared. By and by I was able to recognize that this meant a delay in the transmission of the stimulus from the auricle to the ventricle, and from this inferred that the bundle connecting auricle and ventricle had been damaged. So that we can now recognize that a mid diastolic murmur means not only mitral stenosis but a partial heart block. With the recognition of this delay between the auricular and ventricular systoles we caught the early stage of that condition which goes by the name of Stokes Adams syndrome.

But much more was learnt. I had found that one effect of digitalis was to increase this delay, so that at times the stimulus from the auricle failed to reach the ventricle, and a beat would drop out, and thus was explained one effect of digitalis that had hitherto baffled interpretation.

The continued observation of this patient revealed other important changes. He used to come and see me every two or three weeks. In April, 1904, I found for the first time that his pulse was irregular. On further examination, I found that the mid diastolic murmur had disappeared, while the auricular wave also was absent from his jugular tracing—that is to say, all evidence of activity of both auricles had disappeared—the disappearance of the murmur was a sign of cessation of activity of the left auricle, and the disappearance of the wave in the jugular a sign of the cessation of activity of the right auricle.

This condition continued for a week, then one day I found both murmur and auricular wave had returned and the rhythm had become quite regular. The heart continued thus until the following November, when the irregularity returned with the cessation of auricular activity. This condition persisted till his death ten years later.

One instructive point was this. I had observed, as I have said, that when these events happened heart failure usually set in, sometimes speedily. This man was unconscious of the changes, and he continued his laborious work—that of a mechanical engineer—with no signs of heart failure. On seeking for a reason, I found that in his case though the rhythm had become irregular the rate had not increased, both before and after the rate was about 60.

The reason for this was no doubt the presence of the partial heart block. I had recognized that digitalis acted on the bundle and produced heart block. The cases that did badly and suffered from heart failure after the onset of auricular fibrillation had the rate of the heart greatly increased. It occurred to me, if I could imitate this heart block by using digitalis, the ventricle in these cases might be kept slow and heart failure prevented. This was found to be correct, and in this way was found that treatment which has robbed auricular fibrillation of much of its peril.

The Basis of a Scientific Therapy.

A matter which strikes everyone who gives it attention is the curious difference between theoretical therapy and practical.

"I have the experimental pharmacologist demonstrating

to the student with precision the effects of remedies by animal experiment. The student as soon as he enters the wards of the hospital finds a different atmosphere—drugs are administered without any reference to their experimental effects, and he finds the knowledge he has acquired in his pharmacological course of no use.

The pharmacologist scoffs at the clinician as unscientific and as employing empirical methods. The clinician replies that the laboratory teaching is academic and unpractical.

I have already remarked that the action of digitalis on the human heart was not understood, and when I made the observations on the effects of digitalis during this inquiry into mitral stenosis, I was struck by the variety of results I obtained. In one patient digitalis would produce dropping out of beats due to heart block, in another it would cause the whole heart to stand still for two or three seconds and then the ventricle would start off by itself; in another great slowing would result, and so on. When I looked at these patients individually, I found they all suffered from damaged hearts, but there were differences in the kind of damage, and I therefore formulated the theory that the action of digitalis is modified by the nature of the disease. It is manifest that the pharmacologist could never find this out, and his results were different, therefore, from that of the clinician. On the other hand, the knowledge of heart irregularities was so defective that the clinical observer could not recognize them, but saw that they were different from the description given by the laboratory observer. That is the reason of the failure of the pharmacologist to explain the action of digitalis on the human heart, and the reason why the clinician could not recognize it.

This principle, at first dimly perceived, holds out the possibility of directing therapeutical research on lines based upon sound principles. One of the least creditable fields of knowledge is the therapeutic. While many drugs are usefully employed, it must be confessed that our knowledge of the action of remedies is sadly lacking in accuracy. To this defect must be attributed that wide diversity of opinion as to the action of the simpler remedies and that confusion which bewilders the student. This inquiry into the nature of symptoms led us at St. Andrews to recognize that a great mass of symptoms is due to disturbances of normal reflexes. When a man falls ill, due, say, to the invasion of his body by a microbe, the toxins of this microbe produce the ill health by upsetting the normal reflexes, and we recognize these disturbances in the signs of disease.

The administration of a drug such as atropine acts in the same way by disturbing certain reflexes. Indeed, the effect of atropine may be described as an imitation disease. One of its effects is to paralyse the peripheral ends of the vagus and cause an increase in the heart rate. If digitalis is given it is without effect, because digitalis stimulates the vagus, and under atropine it is paralysed.

In certain infections the heart rate is increased because the toxins act like atropine, and digitalis does not slow the heart because the vagus is paralysed, and that is the reason why digitalis does not slow the heart in a great many febrile and other conditions.

In auricular fibrillation the increased pulse rate is due to a totally different mechanism. Here the ventricles are stimulated to increased rate by a shower of stimuli from the fibrillating auricle. The vagus is unaffected, and so the digitalis, when given, acts as we have seen on the bundle which conveys the stimulus from auricle to ventricle, and it is probably in this way that digitalis is so effective in slowing the heart rate in auricular fibrillation.

The First Step in Investigating Disease

Many visitors come to see our institute at St. Andrews, and they go away disappointed at what they see. Our work is not spectacular—our chief method is seen to be a general practitioner quietly asking questions of a patient who has little the matter with him. A learned physician one day was being shown over the institute. He came to the general practitioner engaged in his work. He looked at the notes and said, "Ah! applying hospital methods to general practice?" "No," I replied, "we are training ourselves how to examine patients. We find that students are never trained to examine patients so as to fit them for general practice." "Oh, nonsense!" said he, "they are well enough trained." "Well," I replied, "you have been teaching students at least for twenty-five years?"

The maxillary antra and nasal sinuses should be carefully examined by illumination, etc., for a possible source of infection. The uterus and genital organs also should be examined for possible sources of infection. In my experience infections from these organs apart from gonorrhoea are very rarely the cause of arthritis and allied conditions. Any focus of suppuration may act as the cause of a general infective arthritis; thus infected wounds or a suppurating joint may give rise to a non-suppurating general arthritis. (McCrae.)

MORBID ANATOMY.

The morbid changes in the joints in this condition have been described by Strangeways and others. Briefly, they consist of swelling and hyperaemia of the synovial membrane, and in the villous form this may attain a high degree of proliferation. The fluid in the joint is slightly turbid from the presence of small fibrous deposits, and usually contains lymphocytes and a few polynuclear cells. Later the capsule of the joint becomes involved, and inflammatory processes are set up which may go on to thickening and contraction. The cartilage of the joint becomes affected, the surface being roughened and irregular with small elevations, and a fibrous tissue degeneration involves it with blood vessels spreading through. The cartilage becomes thinned and may almost entirely disappear.

Atrophic changes occur in the bones and the density becomes diminished. At the apposed surfaces absorption occurs in advanced cases, and at the periphery osteophytic outgrowths of softish bone occur so that a mushroom appearance may be produced. In the synovial fringes thickened fibrous nodules partly calcified may develop, and these sometimes become dislodged, forming loose bodies in the joint. In extreme cases a fibrous or partly bony ankylosis may result.

The changes to be seen in x-ray photographs are rarefaction of the involved bone, a fuzziness of the articular surface, as if a very thin layer of fine cotton-wool covered them, due to the irregularity of the surface of the bone in consequence of the changes described. The clear space between the opposed bones is diminished as a result of cartilage absorption. Loose osteophytes may be seen in some cases. Lipping of the bones or slight outgrowths may be seen.

SYMPTOMS AND PHYSICAL SIGNS.

It cannot be too strongly insisted upon that the most careful examination must be made to determine exactly what structures are affected. Each joint should be carefully examined for evidence of swelling, pain on movement, crepitation, creaking or grating.

A careful examination should be made of the bursae around the joints, of the tendons, and the tendon sheaths.

Wasting of the muscles above and below an affected joint is sure to be present in arthritis of appreciable duration, and where the hands and feet are involved trophic changes, such as sweating, pallor and thinning of the skin, and defective circulation, are usually present. The freedom of movement in all directions of each joint should be carefully tested and any limitation noticed.

When there are symptoms of fibrositis a close examination should be made to determine whether the fasciae, muscles, tendons, or nerve trunks are involved. Pressure should be made on the affected part, and where brachial neuritis or sciatica is suspected the nerve trunks should be pressed upon to see if tenderness is elicited, and movements of the limbs made which will put on stretch the nerve trunks, and so elicit marked pain if they are affected.

It is not proposed to give in detail the signs and symptoms of infective arthritis. Some cases begin with an acute onset of pyrexia and general in addition to the local symptoms. Undoubtedly cases of infective arthritis occur which completely clear up with rest and treatment after an attack of moderate duration. Generally, however, the condition is progressive, and unless the cause of the disease is removed no permanent improvement will result.

In the majority of cases of arthritis the onset is insidious and gradual, a localized pain and swelling in an affected joint or joints occurs, and this progresses, other joints being involved, usually in a comparatively symmetrical manner. The involvement of the joints is usually accompanied by general pains, described as rheumatic in nature,

and no fever may occur, though malaise, depression, headaches, anaemia, and debility are usual. Cardiac complications are absent as a rule, and beyond the joint affections, and the general malaise and ill health often associated with marked wasting, little is found. The tendon reflexes over affected joints are usually exaggerated, owing to the excitability of the reflex nervous are caused thereby. The temporo-maxillary joint is involved much more often in infective arthritis, and this is an important point in diagnosis. The earliest joints involved are often the metacarpo-carpal joints of the thumb and the phalangeal or metacarpal or carpal joints of the hands, but any joint may be primarily affected.

Heberden's nodes, the fibrous enlargements on each side of the distal ends of the second phalanges of the hands, are often present in cases of infective arthritis. Osler states that these are rarely associated with serious involvement of the larger joints, with which my experience entirely agrees. A hopeful feature of them is that they have been regarded as a sign of longevity.

TREATMENT.

The most important step is first to find out the cause of the infection which has given rise to the arthritis. The measures to be adopted have been already indicated. A careful and complete clinical examination should be made to find out any possible source of infection, and this should be supplemented by an x-ray examination of the teeth and bacteriological examination of the stools and urine.

In acute cases with pyrexia absolute rest in bed is essential and complete rest of the affected joints. Local applications of heat, such as electric-light baths, or fomentations, iodine poultices, etc., are of value. Salicylates, which are of such striking benefit in rheumatic fever, are of little value. Indeed, drugs, except for the relief of pain—such as pyramidon and phenacetin—are not of much use. Intestinal antiseptics—such as guaiacol carbonate gr. x t.d.s. or cyllin miii—should be given. A new intestinal antiseptic, "dimol," which is said to have fifteen times the disinfecting power of phenol and to be non-toxic, may be given in doses of 2 to 4 grains in keratin capsules three times daily. Bier's treatment is of value until the exciting cause has been determined; an elastic bandage is placed round the limb above the affected joint so as to obstruct the veins but not the arteries, and is left on for twenty minutes daily.

In cases without pyrexia, if there are signs of active inflammation in the joint, such as redness, heat, swelling, or pain, rest of the joint is essential, and local and general treatment as above should be prescribed. Iodine is of value. Collosol iodine in doses of 1 to 2 drachms with a wineglassful of water should be given twice daily. Iodides, if tolerated, may be given instead.

As soon as the source of infection is found this should be eradicated if possible. Where the teeth are implicated or an apical dental infection is found, the affected teeth should be removed and placed in a sterile vessel for bacteriological examination. A satisfactory way of dealing with an apical infection is Gardner's method of sterilizing the infected bone area by removal of the alveolar layer over the site of the lesion and curetting away the diseased tissue, and sterilization after removal of the offending tooth. This involves a cutting operation over the gum of the affected part.

Vaccine Treatment.—This is of great value, but it cannot be too strongly insisted upon that it must be accompanied by removal of the causal infections. Affected teeth should be removed, and a vaccine prepared after guarding against possible contamination of the teeth removed with normal streptococcal organism found in the mouth. A course of at least three months of vaccine treatment is usually required, with weekly and later fortnightly doses. It is a wise procedure to have a bacteriological examination of the faeces made, even if a dental streptococcal infection has been found. Usually an abnormal streptococcal intestinal infection is also present in such cases. It is then an advantage to use for treatment a combined vaccine made with equal proportions of the dental and intestinal streptococci. In cases where the teeth have been removed and arthritis still persists, an examination of the faeces or colon washings will usually indicate a streptococcal infection, and in such cases vaccine treatment may give benefit.

FIG. 2.—Showing the atrophy of the thighs, the enlarged tensor fasciae femoris muscles, the early "taille de guêpe," and the flattening of the chest.

FIG. 3.—Showing the enlargement of the spinati and the atrophy of the rhomboids and lower muscles.

Electrical Treatment.—In chronic and subacute cases electric light or radiant heat treatment should be given daily or on alternate days, and this should be immediately followed by ionization with iodine ions, a 2 per cent. solution of lithium iodide being placed on the lint of the kathode. In cases where much pain is present ionization with salicylic acid ions is of value. Diathermy is of value in relief of pain.

Massage, etc.—When there are no signs of active inflammation and the infective cause has been removed, massage and movements of the joints are indicated. Where the joint movements are much limited in such cases breaking down of adhesions under an anaesthetic or suitable surgical measures may be adopted.

Diet.—In pyrexial cases the diet should be mainly liquid. It must be borne in mind that most cases of non-specific infective arthritis require a diet of high nutritive value, and attention should be directed towards giving a dietary rich in vitamins. Milk, cream, eggs, the unheated juice of fresh lemons or oranges, fresh fruits and vegetables, fish, chicken, and meat, may be given according to the digestive capacity of the patient. If tolerated, milk fermented with lactic acid bacilli is of value in controlling intestinal fermentation. Cod-liver oil and malt, or one of the many substitutes for this now on the market, may also be given with advantage.

In cases of fibrositis of aponeuroses and tendons local electric light and massage gives the best results; diathermy and ionization are sometimes beneficial. In perineuritis, such as sciatica and brachial neuritis, frequent application of electric light gives the best results. Ionization is sometimes of value, and if there is much pain salicylate ions should be used instead of iodine. Iodine may be given internally, and aspirin, phenacetin, or pyramidon for relief of pain. The local application of a mixture of equal parts of chloral, menthol, and camphor on gauze covered by oil silk is very helpful. Complete rest during the acute stage is necessary. In bursitis and teno-synovitis local treatment by electric light and ionization is indicated. In chronic villous synovitis where the above measures fail, the opening of the joint surgically and removal of the villous outgrowths has given good results.

PROGNOSIS.

Where a case of early arthritis is subjected to investigation and treatment on the above lines a complete cure can be effected. In cases of long standing the inflammatory changes are often progressive in nature and removal of the primary cause may do little good because the infective process is being carried on by a secondary intestinal infection. In such cases everything possible should be done to remove both the primary and secondary causes of infection, and when the signs of active inflammation in the joints have ceased measures should be taken to improve the mobility of the joints and muscular tone by massage and movements.

COCYGEAL FISTULAE.

BY

J. P. LOCKHART-MUMMERY, F.R.C.S.ENG.,

SENIOR SURGEON, ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM.

[With Special Plate.]

THERE is a type of fistula in the anal region which for years was a source of difficulty to surgeons, and still causes much embarrassment unless its nature is recognized. Fistulae of this type cannot be made to heal by the ordinary operative procedure, and failure to make them close is common.

They are always situated over the tip of the coccyx, or very close to it, and behind the anus. There is no internal opening, but frequently there are several external openings. The external openings are small, and discharge a thin serous fluid, or sometimes ordinary pus. The parts around are tender and often inflamed, and the condition causes the patient considerable discomfort when sitting, as the tender area is just at the point where most pressure occurs in the ordinary sitting position. The following case well illustrates the type:

A gentleman, aged 45, as the result, he thought, of a slight blow on the posterior part of the perineum, developed a painful abscess behind the anus. This abscess was opened and scraped

by his medical adviser, but refused to heal. Another operation was then performed and the fistula laid freely open into the rectum, although no actual track could be found opening in this direction. After many weeks lying up and a further unsuccessful operation the fistula was still unhealed, and he was brought to see me. I recognized the nature of the condition and completely excised the fistulous area, after which healing took place without further trouble.

It is quite common to find, as in this case, that several previous operations have been performed without success.

Several years ago the late Mr. Goodall described a number of cases of fistulae over the coccyx, which were difficult to heal, but he did not recognize their nature.

The true nature of these fistulae over the coccyx was recognized by Sir John Bland-Sutton, and his book on *Tumours* contains (fourth edition, p. 436) a description of them. They are congenital—remnants of the faulty coalescence of the cutaneous covering of the back during early embryonic life. They are an exaggeration of the "post-anal dimple" often seen in this situation, and are in reality sequestration dermoids due to skin being shut off from the external surface. The fistulous tracks are lined with skin, and it is for this reason that they will not heal when laid open. In one case, on laying open such a fistula, I found a lock of hair nearly an inch long growing from the walls. It is a curious fact that they may exist for many years without causing any trouble.

The microphotographs accompanying this article show the appearances in cross section of the fistulous track after excision; it can clearly be seen that they are lined with epithelium. Often, of course, considerable modification has occurred in their structure from secondary inflammatory changes, but it will be always possible to demonstrate the presence of epithelial cells in the lining membrane of some part of the fistula. There is often a considerable deposit of fibrous tissue around the fistulae, even when no operation has previously been performed. When, as is usual, one or more operations have been performed, a very complicated condition may be found, but the situation of the external opening near the tip of the coccyx will generally make it possible to surmise the nature of the condition. Often the condition is not noticed until, as the result of some slight injury, a small abscess forms and the parts become painful. Treatment consists in completely cutting out the fistulous tracks. An incision should be made around the external openings and deepened until healthy fat is exposed; then the whole area is cut out down to the coccyx, care being taken to watch for any signs of side tracks, which are often present. The dissection will as a rule go down to the coccyx, and a fairly large wound will result. This is best left to granulate, and will soon fill in with healthy tissue. It is not necessary to excise the coccyx unless a fistulous track is discovered passing up in front of it, when, of course, the track must be followed to its termination.

These congenital coccygeal fistulae are closely related to the dermoid cysts sometimes found behind the rectum, but whereas the fistulae lie superficial to the coccyx, the dermoids are usually on the front or upper surface of the coccyx and between it and the rectum.

These congenital fistulae seldom cause serious trouble, and except as the result of surgical interference never open into the rectum. The chief point of interest about them is that owing to their being lined with skin they will not heal unless completely cut out.

ACUTE OSTEOMYELITIS OF THE LONG BONES IN CHILDREN.*

BY

ALEX. MITCHELL, M.A., M.Ch.,

SURGEON AND LECTURER IN CLINICAL SURGERY, ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN; ASSISTANT SURGEON, ROYAL ABERDEEN INFIRMARY.

[With Special Plate.]

ONE cannot work in a children's hospital without being struck by the fact that there is always going on a certain waste of valuable human life, or at least of future efficiency and wage-earning capacity. This occurs in cases in which, through some delay in diagnosis or some unfortunate choice as to a method of treatment, there is lost

* A paper read before the Aberdeen Medico-Chirurgical Society.

the opportunity of saving a life or of putting a child in a fair way to become a useful citizen. The reasons for this are of course the suddenness with which acute disease begins in early life, the rapid course it so often runs, and the great variation of symptoms in any particular disease. These factors make diagnosis difficult for the practitioner, and the surgeon is too often presented with a case in which the indications as to the best possible line of treatment are none too clear. These observations apply, I think, most particularly to acute (septic) osteomyelitis of the long bones. In the former two a great advance has been made in the last ten years, but I cannot help thinking that in the last neither as regards immediate recovery nor as to late functional capacity has there been a very great improvement in results as compared with the state of affairs when this was the subject of discussion at a previous meeting of this society (about ten years ago).

Although in a few cases the general infection is so severe, and the local response about the infected bone so slight, that diagnosis is practically impossible, usually there are some local signs which should lead us to suspect what is going on. While I fully appreciate the difficulties of diagnosis, it seems to me, from what I have seen of those cases as they come into hospital, and from a study of their histories, that there are two classes of cases in which undue delay in arriving at a diagnosis occurs:

(1) Cases in which a child has been ill for several days without any apparent cause, and a systematic examination of the ends of the long bones has not been made. This point has been constantly emphasized by Dr. Rose in all his teaching.

(2) Cases in which, during an acute illness, an abscess has rapidly formed over the front of the tibia. A small incision has been made, and pus allowed to escape. The true nature of the condition has evidently not been realized, and home treatment continued until one or more of the other bones have been infected. These cases rarely recover.

On the other hand, whatever perfection we may arrive at in rapidity of diagnosis, the fact that the local disturbance may be accompanied or preceded by a severe septicaemia means that the initial mortality must always be fairly high until we can find some more prompt and efficient means of serum therapy than we are at present equipped with.

In cases that recover after operation there is always a great possibility of the functions of affected limbs being permanently impaired. This may be due to:

- (a) Direct extension of infection to periarticular tissues or to the joints themselves.
- (b) Infection of joints through the blood stream.
- (c) Permanent loss of bone substance through destruction of tissues capable of forming new bone.
- (d) Irregular growth, owing to interference with epiphyseal ends.
- (e) Ineffective after-treatment where the whole thickness of the bone has been removed.
- (f) Loss of muscle function from sepsis and from disuse.

The treatment of acute osteomyelitis must vary in some degree according to the type of case which we have to deal with.

While any attempt at classification must be faulty and subject to criticism, I feel, none the less, that if any attempt is to be made to indicate lines of treatment, this must be based on a consideration of the types of case, for in this way only can we hope, on the one hand, to avoid unnecessarily mutilating operations, and on the other, to apply sufficiently radical treatment when it is required. I think we may take it as a generally accepted fact that the process begins at the end of the shaft near to the epiphyseal junction. The only apparent contradiction to this is that one sometimes meets with a fairly acute form commencing high up in the shaft of the femur, but here the focus will be found to be close to an epiphyseal junction—namely, that of the small trochanter.

We may take it also that the so-called "subperiosteal abscess" described in the textbooks is in actual practice very rare, and that an abscess under the periosteum is almost invariably proved to have its origin in an underlying focus of infection in the bone itself.

Keeping these two points in view, and feeling the need of something to justify not advocating the same treatment in every case, I venture to submit the following rough classification into three types, and to discuss the treatment of each.

Type 1.

A case presents signs suggestive of localized mischief at the end of a long bone. The history is a comparatively long one, and the general infection is manifestly not at all severe. Incision reveals the presence of a localized collection of pus under the periosteum, which is separated from the bone only over the abscess area. Here removal of the bone denuded of periosteum will allow for drainage of the medulla, which should not be curetted out, and will—provided that all the denuded bone has been removed and given appropriate after-treatment—usually ensure a good result.

Type 2.

A short history, say twenty-four hours or less, of symptoms of severe general infection with strictly localized but very severe tenderness on pressure at one spot at the end of the shaft. On incision pus is not seen, but the periosteum has begun to separate, or is very easily separated, over the small area where tenderness was made out. When the bone is opened, which it should be freely, a little pus may be detected, but sometimes pus cannot be seen. If cultures be taken from the medulla, a vigorous growth of a staphylococcus, or a streptococcus, will result. In such a case, if treatment has been given at a sufficiently early point in the course of the disease, convalescence will be rapid and the final result good.

Type 3.

The most common type of osteomyelitis seen in hospital practice is that in which there is considerable denudation of periosteum. In some cases the bone will be free of periosteum in almost the whole length of one aspect; in others the stripping seems to have run round the shaft. In the most advanced stage the shaft is completely denuded of periosteum. This variety is only too familiar to us all, and it is the type most commonly met with in which disease of average severity has established itself in the shaft of a long bone.

The usual textbook teaching as to the treatment of those cases may be summed up as follows:

That a good-sized piece of bone should be chiselled out, and that this will amply provide for drainage of infected material, and will give the patient a good chance of recovery. More bone may be removed later if necessary; even the whole shaft may be resected, but if this is to be done it should not be undertaken for some time after, say about two months, in order to give time for new bone to form.

I submit that from the point of view of immediate recovery, and also looking to the possibility of obtaining the best functional result in the future, this treatment has not proved to be satisfactory, and I believe that the correct treatment is to resect (subperiosteally) the whole thickness of the shaft, not necessarily the whole length, but always the whole diameter of the part over which the periosteum does not exhibit a normal degree of attachment to the underlying bone—an operation previously described and strongly advocated to this society by Sir Henry Gray.²

While one has no hesitation in applying it to the humerus and to the femur in suitable cases, fortunately the bone for which this operation is most frequently demanded is the tibia, where, owing to the splinting afforded by the fibula and to the distribution of the muscle attachments, the conditions for operation, after-treatment, and for good end-results are ideal.

The arguments put forward against this apparently too drastic operation are:

(1) That it is not necessary, as if chiselling be freely done it is quite sufficient. This theoretically is true, but the practical difficulty is that it is very difficult to judge when one has chiselled away all the bad bone, and if any is left there is always risk of the infection spreading locally or to other bones. From what I have seen of this operation in the type of case under consideration, the results are not at all good, and a certain number of cases have ended by amputation.

(2) That resection is more difficult and dangerous than chiselling, and that the mortality from it is very high. In the past five years I have resected completely ten tibias, with two deaths, and six partially, with two deaths. I do not think, when one considers the nature of the disease, that one can look for a much lower mortality than this.

(3) That the bone will not regrow. I do not think that in children one need have any fear of this. I have seen only one case in which growth failed, and one in which it was exceptionally slow. Usually the bone regrows in from three to six months. The bone seems to grow from the epiphyseal ends, and abundantly from the bone-forming cells adherent to the under-surface of the periosteum. A study of skiagrams taken at various stages of regrowth and examination of the limb itself shows this beyond dispute. This is apparently in contradiction to the experiments of Gallic and Robertson,³ but their work as to the experiments of Gallic and Robertson,³ but their work as

regards this point is based mainly on animal experiments and on clinical observation made on adults. Great stress has always been laid on the value of inflammation as a stimulant to the activities of the bone-forming cells which get separated up with the periosteum. The finding I am tempted to deduce from my own cases is that while inflammation does, as pointed out by McKewan and others, promote the re-formation of bone in this way, where the sepsis has been very severe, or where pus under the periosteum has been kept too long under tension, the subperiosteal osteogenic cells get completely destroyed—giving a possible explanation for the occasional case of failure of growth that occurs. Also that if a septic bone shaft be allowed to remain *in situ*, it may sometimes, by keeping up sepsis, act as a deterrent rather than as a stimulant to regrowth of healthy bone, and that therefore, after it has become septic, the quicker it is removed the better. If in any rare case bone growth should fail, one can always get over the difficulty by grafting bone from the other tibia, as I demonstrated by a case shown here recently.

(4) The last argument advanced against resection is that the limb is difficult to manage after, and that the functional results are poor. The after-treatment is certainly difficult, but it can be satisfactorily done, and the results can be judged from the cases shown. On the other hand, when incomplete operation has been done, and sinuses have continued to discharge for long periods, necessitating frequent secondary operations and prolonged hospital treatment, the results as regards the adjacent joints are notoriously bad.

In performing complete removal of the shaft of the tibia the end of the shaft which shows signs of least infection should be divided by a Gigli saw, or by a broad sharp chisel. The bone then can be usually lifted out, as the other end, at which the infection has commenced, is free, or is easily separated from the epiphysis. The periosteal bed is then cleaned up with a little peroxide of hydrogen or eusol, and is packed with gauze strips, which are kept in position by two or three temporary skin sutures. The operation can be performed very speedily. Secondary suture of the periosteum and of the skin is performed in three or four days, and Carrel-Dakin treatment commenced by tubes placed within the periosteum. The Carrel-Dakin tubes can be removed in a few days. The limb is immobilized and extended on a Thomas knee-splint.

Early active movement of the muscles is of the utmost importance in stimulating bone growth, and in helping to form a limb which is straight and free from deformity. The Thomas splint is to be laid aside whenever the shaft of the bone can be felt to have attained to any appreciable degree of firmness. For the lower limb a calliper splint will be used, and walking begun at the earliest possible time. Massage and faradism are of value in keeping up the tone of muscles, but active movement is most useful.

Although these remarks are, strictly speaking, applicable only to osteomyelitis in children, I would like to raise the question as to whether, taking into account the present position of bone transplantation, we might with advantage be less timid in our treatment of adult cases, as I think by so doing we might save more lives and get better results than we have done in the past.

Generally speaking, cultures from the medulla of the bone and a blood culture should be made in every case. An autogenous vaccine may be of value in after-treatment, and it is always of advantage to know if there is an active septicæmia present. Vaccines and serums, though of value as adjuncts to operative treatment, do not seem likely to be able to replace it unless in extremely mild cases.

The value of transfusion of blood from individuals who have been previously vaccinated with the particular organism concerned has been proved to be of value in certain septic cases,¹ but its use here as a routine treatment in acute cases presents obvious difficulties.

It seems, therefore, that the question of treatment hinges, at present, mainly on the type of operation to be performed, and I hope that by stating my own views, even at the risk of being considered too dogmatic, I may provoke some discussion and derive some help therefrom.

REFERENCES.

A CASE OF IDIOPATHIC MUSCULAR DYSTROPHY.

H. S. CARTER, BY W. FLEMING,
M.B., Ch.B. L.R.C.P., L.R.C.S. Ed.

(From the Ministry of Pensions Hospital, Beckett Park, Leeds.)

[With Special Plate.]

A MAN, aged 24, was admitted to this hospital in January, 1921, his invaliding disability being recorded as synovitis of the left knee.

His history was as follows. He enlisted early during the war, and served for some time at home. As far as he can remember he was perfectly well and of category A1 until Easter, 1916. About this time he was accidentally kicked on the left knee by a horse. The injured part became swollen and painful, and he was resting at his billet and doing no duty for six weeks. He was not admitted to hospital. In about two months he was better and had very little trouble, except that he noticed his knee give way very occasionally when walking, and rather more often when the limb was under less deliberate control, as in running or in making sudden movements. He was put on fatigue work until he went to France in August, 1917, where he continued in a labour corps. Early in 1918 he fell in the street owing to his left knee giving way, and he dates his downward progress from this.

He was demobilized in February, 1919, and his attributable disability was recorded as synovitis of the left knee joint.

Shortly after returning to civil life he noticed wasting of the left thigh, and had pain in the back and in the left hip region. Tuberculosis of the left hip-joint was suspected, but x-ray examination proved negative. Shortly afterwards the right thigh muscles began to waste, and he found that walking became increasingly difficult. Going upstairs became a great task, and he has often been carried up by members of his family. Up to the time of admission to this hospital he had noticed nothing else wrong. Difficulty in walking, with wasting of the thighs and pain in the back, were his complaints. His general health he regarded as good.

Examination.

The patient is a rather thin, pale youth, who walks with the aid of a stick. His gait is clumsy, wide-based, and waddling, with throwing out of the feet, and there is a noticeable lordosis even when he is fully dressed. Stripped he presents a typical picture of muscular dystrophy. The left knee-joint shows no signs of synovitis now and differs in no way from its fellow.

There is much wasting of both thighs. The atrophy, although he has not noticed it himself, has obviously extended to the buttocks and lower part of the trunk. The face, arms, hands, and the legs below the knees appear normal. There is profound wasting of both quadriceps, both sets of adductors, the psoas groups, the abdominal oblique muscles on both sides, and to a lesser extent of the hamstrings, glutei, and latissimus dorsi muscles, the serrati and the rhomboids. Both quadriceps on contraction show two or three ball-shaped relative swellings at intervals in the middles of the muscles. They are not strong enough to extend the legs at the knees. The tensor fasciæ femoris on each side is hypertrophied and is used in a compensatory manner in extending the legs and in maintaining an erect posture. In raising the trunk at right angles to the lower limbs the recti abdominis apparently play a principal part, but he is obliged to call in the assistance of his arms. There is some relative hypertrophy, no doubt partly compensatory, of the spinati. He rises from the supine position in the typical "leg climbing" manner. X-ray examination of the hip-joints and spine shows no bony changes. The affected muscles show no fibrillary tremors; their electrical responses are diminished to both faradism and galvanism, but there is no reaction of degeneration and no myasthenic reaction.

The reflexes are normal except where profound atrophy of the muscles concerned prevents their elicitation. There is no dissociation of sensation—tactile, bone, joint, muscle, and temperature senses being unaltered. The other functions of the central nervous system also present no abnormality.

Apparently in this case there is as yet no evidence of familial affection. The patient has several brothers, all younger than himself, who are healthy.

Our reason for reporting this case lies in the fact that myopathy starting in the thigh muscles and described as the type of Loyden, Moebius, and Zimmerlin is of some rarity.

We have to thank Dr. C. E. Ligertwood, medical superintendent of this hospital, for permission to record the case.

ARTIFICIAL PNEUMOTHORAX.*

BY

CLIVE RIVIERE, M.D., F.R.C.P.,

PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,
AND EAST LONDON HOSPITAL FOR CHILDREN.

It is now some thirty years since artificial pneumothorax came into practical use in the treatment of pulmonary tuberculosis. During this period the roll of its adherents has steadily increased as its value has become more and more widely recognized, and the opposition which new methods always have to encounter, and which in this case has never been very strenuous, appears to have died down or disappeared. At the present time the treatment is practised in most of our sanatoriums, and in London the County Council have arranged to supply it to patients of the hospital class. As to the opposition it has encountered, such opposition as I have observed has shown itself rather in a studied neglect of the method than in open antagonism. Among those who have really investigated and practised the treatment I have neither met nor read of opposing opinions as to its value. This unanimity among the initiated has seemed to me nothing less than remarkable; for it is a treatment that involves no small amount of art and judgement, as well as some knowledge, and the success achieved might well be expected to differ, and differ widely, in the hands of various operators. If there have been any persistently "unlucky" centres, their fame has never reached my ears; and in this connexion it is important that the class of case treated be taken into careful consideration before any judgement is passed on results.

Those who reserve the treatment for advanced and otherwise hopeless patients may well find ill-fame in spite of the utmost skill; on the other hand, those who treat early cases by pneumothorax will achieve a success which they in no way deserve. The peculiarly individual character of each pneumothorax case, both as to the nature and amount of disease, and the varying features of the "gas pad" applied, defeats all efforts to classify the results; those who wish to convince themselves must do so on individual cases. The return to health of a single case of advanced unilateral disease under pneumothorax treatment will have an effect on their minds which statistics will neither increase nor diminish. I shall not, therefore, waste time now over the results, feeling that I shall open this discussion more usefully by inviting your remarks and criticisms over a wider field. If we achieve the best possible in the selection of cases and in the art of their treatment, we may safely leave the results to win a steady recognition for themselves.

Indications for Treatment.

First, as to indications for pneumothorax treatment—for the first essential to success lies in the proper selection of cases—these must miss on the one hand those who can recover by other means, and, on the other hand, those for whom a pneumothorax will merely mean acceleration of their inevitable end. Forlanini's dictum can, perhaps, hardly be improved upon. "Pneumothorax," he remarked, "is indicated every time that life is threatened by the extension of a local lesion." This is not to say, of course, that all such cases are suitable, since contraindications may exist, but in all such cases the question of a pneumothorax demands investigation. In practice it is surprising how many cases with disease of the whole of one lung turn up for this treatment. This is not, I am convinced, as a rule due to the negligence of physicians who have allowed disease to spread from apex to base before they awoke to the need of doing something. But disease in these cases

is of hilus origin, has progressed in the deep parts of the lung, and on reaching the surface is soon evident to auscultation over the whole of one side. In such patients the *x* rays will often discover advanced disease of the opposite lung also, though to the stethoscope it may appear quite sound because the process has not yet reached the surface. For this reason it is imperative, where at all possible, that a radiogram be taken before a pneumothorax is embarked on, for above all other considerations the condition of the other lung is the point of the most moment. How much disease may be permitted in the other lung without its forming a contraindication to pneumothorax is a matter which cannot be described on paper, and is often very difficult to decide upon in practice. In my experience the question of activity is of far greater importance in this decision than extent or locality of disease. Rarely is the other lung altogether free of disease unless in pneumonic cases, and in these, nevertheless, the prognosis is bad. But torpid lesions, even of wide extent, may be expected to clear up or improve—the strain of increased function seems to be more than counterbalanced in these cases by the removal of focal reactions and toxæmia, and the effects of the hyperæmia which is probably brought about. Active lesions, on the other hand, tend to spread and get worse. But even to this there may perhaps be exceptions. Many writers, notably to my recollection Mary Latham, and Parfitt and Crombie, have recorded improvement and recovery under pneumothorax in cases where the other lung was so bad as to appear to be a contraindication. In some of these the *x* rays were not used till after the pneumothorax was initiated, and the writers are therefore inclined rather to discount the *x*-ray findings in deciding on the suitability of a case. Nevertheless the *x* ray must be our standby, and if we are to extend our field of treatment to cases of more doubtful suitability it can only be through increased experience of the radiological appearances.

Conducted Riles.

One of the warnings I should like to make while speaking on selection of cases is against mistaking conducted sounds for evidence of disease in the better lung. Sharp consonating crepitations are nearly always audible on the opposite side near the spine, and not infrequently about the axilla, though, curiously enough, they may be less plainly heard in some cases in the area between these points. Often a pneumothorax will unexpectedly remove sounds in the functioning lung, and frequently, I am sure, these sounds have been merely conducted. Crepitations at the base or round the heart on the good side are not always, I think, a contraindication to pneumothorax, where the *x* rays show only quiet peribronchial disease. Such signs may clear as treatment progresses. In cases where the better lung is of doubtful reliability a waiting period of complete rest may improve matters; but in other cases the chance of doing a pneumothorax may, through waiting, pass by and be lost.

Intervals and Quantity of Gas.

To pass over the initial operation, regarding which I have nothing new to remark, and to come straight to the pneumothorax already induced, I should like to refer to the intervals between refills, and to the quantity of gas it is wise to introduce. I find a tendency in this country to give larger fillings, and hence at longer intervals, than are advised by the most experienced Continental authorities. For example, Forlanini in Italy recommended only 200 to 300 c.cm., rising at most to 500 c.cm. at each filling; Dumarest in France rarely leaves longer than three weeks between refills, unless in cases of thickened pleura; Bräuer and Spengler, in Germany and Switzerland respectively, advise 400 to 800 c.cm. In this country fillings of 1,000 c.cm. or more seem to be approved of, and one authority teaches, I am informed, that the intervals achieved should be one month in the first year, two months in the second year, and three months in the third year of treatment. This has led, in one case I believe at least, to the need for two refills on consecutive days before the pneumothorax could be re-established at its former volume and pressure. Such a release of collapse seems to me very undesirable, and is condemned on grounds of post mortem experience by some of the best authorities.

Personally, I have found that it is not possible to fix a standard interval between refills, but each case must be

* Opening paper in a discussion at the Royal Society of Medicine on May 24th, 1921.

law unto itself. For it may happen in one case that a weak mediastinum prevents our achieving complete collapse of the lung, with the result that gas absorption is rapid, and the intervals have to be short—as in a case of mine who even at most achieved a two and a half weeks' interval in the fourth year of treatment, or, on the other hand, pleurisy may early limit absorption and permit of long intervals even near the outset of treatment—as in another patient, whose pneumothorax was started 1st July, and who has received but 1,120 ccm of gas, in two refills, since November last. In my experience it is not wise to let refills run above 700 or 800 ccm, and in most cases 500 ccm, or even less, is a preferable amount. The selected quantity will, of course, determine the interval, and this will be long or short according to the rate of absorption. But, quantity of gas apart, a long interval may allow of expansion and attachment of an imperfectly collapsed lung, as happened in the case of weak mediastinum quoted above. This patient was persuaded on one occasion to lengthen his interval to one month, with the result that the lung became adherent to the chest wall in two places. The doctor who made this recommendation was unaware that the lung, though out of reach of the stethoscope, was but imperfectly collapsed at such pressures as could be used,—a fact which was only revealed to x-ray examination.

Pleural Seclusion

There is no doubt that the x-rays are a well-nigh indispensable adjunct to treatment, alike in the fixing of the optimum pressure at the outset and also in the readjustment of this at intervals during the course of treatment. In process of time even apart from the occurrence of definite pleurisy the pleural layers undergo a chronic inflammatory thickening, followed by contraction, and the mechanical conditions in the chest are thereby altered. Where the heart has been pushed far over to the opposite side it may be seen to return towards the pneumothorax, and therewith the lung may show a tendency towards re-expansion. Under these conditions the interpleural pressure must be steadily raised or the heart and lung will become attached to the chest wall and treatment be interfered with. This readjustment of pressure is a point which must be constantly in mind as treatment progresses. In some cases of pleural thickening and particularly after purulent pleurisy, no amount of pressure will prevent gradual closing up of the cavity and re-expansion of the lung. In such patients, nevertheless, the expected disaster does not always materialize, for the pleural fibrosis may spread through the lung itself, and healing be thus brought about.

Weak Mediastinum.

Another side to the problem of intrapleural pressures is that concerned with weak mediastinum and with ballooning of the pleura. Mediastinal over displacement may be difficult to discover without x-ray examination, for the manometric signs described by certain writers (slow rise of pressure, with stationary points, and small fluctuations) are not, I think, of much value. The symptoms may be vague, and the position of the heart may not appear to be unduly altered. As a matter of fact, the same amount of displacement may be borne without discomfort in one patient but cause marked symptoms in another. The symptoms may amount to vague discomfort, with ill defined distress and inability to sleep, or pseudo asthmatic symptoms may appear, with dyspnoea, an audible wheeze, and attacks which may be of a very alarming character. All these symptoms disappear as soon as their cause is recognized, the pressure lowered, and the mediastinum allowed to recover its tone. In these cases, and in some others where the displacement is less striking, crepitations may appear at the opposite base and may continue for months or years. They are an indication for a lowering of pressure, but such lowering may be impossible without allowing the lung to expand. Where the signs have, from necessity, been allowed to remain I have not seen any harm result from their presence. They represent presumably an oedema of the lung base in most cases, but in some the dryness of the sound, and its appearance or increase immediately after a filling, suggests mere atelectasis as the explanation. In two of my cases, also, I have experienced a definite lung oedema with frothy sputum during the early stages of treatment, owing to circulatory embarrassment in the better lung.

Inflamed Pleura and its Treatment.

A condition which seems to tempt operators to a raising of pressure—always, I am sure, to the patient's harm—is the onset of pleurisy. This is illustrated by a chart, among many I have seen, which came under my notice a few days ago. At the sixth injection the pressure was raised for the first time to the modest figure of $-3+2$, four days later fluid was found, and the pressure was $+1+8$, and yet 40 ccm were put in and the pressure raised to $+3+9$; at a later stage in the same case a return of fluid is noted, and the same increase of pressure was instituted, though it had been kept low in the interval. I do not regard this as a rational procedure, but agree with Continental observers that we should hold our hand, and even avoid puncture altogether, during the earlier stages of pleurisy, since such interference may aggravate the inflammation. Moreover, it may lead, as I have seen in these cases, to troublesome displacement of the mediastinum. There is, fortunately, no need for puncture during the early stages of pleurisy, since gas absorption almost ceases, but it is, I fancy, the small amount of gas which can be put in that tempts those who do puncture to raise the pressure. The loss of resilience due to inflammatory congestion must not be confused with the stiffness of chronic thickening, in which condition, of course, high pressures can and should be employed.

"Ballooning" of the pleura towards the healthy side at certain weak spots and particularly in front under the sternum between the first and fourth rib articulations, is an occurrence which is quite common, but has not attracted a large amount of attention. It reveals itself by giving the physical signs of a gas pocket, and is generally visible to x-rays as an elliptical encroachment on the healthy side with a visible sharp border. I have so far seen no harmful results accompanying this occurrence.

Surgical Treatment of Adhesions.

A subject of the greatest moment, in that it promises to open a doorway from pneumothorax treatment into wider fields, is the surgical treatment of adhesions and especially of adherent pleura. Localized adhesions, if solitary or few, can be divided without opening the chest by the galvanocautery or with a tenotome. Jacobaeus's method consists in the introduction of an instrument called the thoracoscope, with which the adhesions are visualized, and thereafter in the introduction of a cannula in the neighbourhood of the adhesion, and its severance by a galvanocautery introduced through the cannula. The technique is difficult, but a good deal of success has attended its use in skilful hands, as may be gathered by an article by the Norwegian Holmboe in the October, 1919, number of *Tubercle*. Division of adhesions with a tenotome has been practised by Vorrison Davies in this country, the operation being carried out under the x-rays.

For cases where a few strong adhesions are preventing treatment one or other of these methods may succeed, with multiple adhesions I am inclined to think opening the chest may prove a more satisfactory procedure.

About a year ago, in a private patient for whom I produced a pneumothorax, the lung failed to collapse adequately, owing to the presence of numerous firm adhesions to the chest wall. Persistent low pressures did not lead to their stretching, or separation and higher pressures were barred on account of the presence of large and numerous cavities which I feared might be torn open. Recently the condition was becoming less and less satisfactory, owing to the further shortening of the adhesions as the result of chronic pleural inflammation and fibrosis. Some three weeks back Mr. Romans at my request opened the chest wall through the third space and divided, with scissors and galvanocautery, seven strong adhesions, mostly rounded bands but one with a fairly wide attachment. This allowed the lung to collapse, which it did to a moderate degree only, being solid with disease. The actual operation took twenty-three minutes, was done under gas and oxygen only, and no rib resection was contemplated or performed, an ample opening being obtained between the spaces with special retractors. The operation led to very little reaction or other disturbance, except for the expected temporary increase of sputum. A refill was given on the seventh day and again on the twelfth and all seems well save for doubts as to the ultimate behaviour of the functioning lung.

Separation of Adherent Lung

Of recent years the separation of lung adherent over a large surface to the chest wall has been attempted on various occasions. In 1918 Professor Schettmüller, of Hamburg Eppendorf, described how he advised the trial

of this for a case in which Jessen had found the pleural surfaces adherent. Jessen refused to attempt it, but Sudeck removed most of the fourth rib and separated many adhesions by hand, and a good result was recorded. Edon of Jena, stimulated by this, operated on a case, but found the surfaces very difficult to separate, and had to confess that the pneumothorax obtained was only partly intrapleural. Some days later the patient ruptured a lung cavity during the act of coughing. Ulrici also treated a case by this means, but the operation lasted one and a half hours, and the patient succumbed eventually to extension of disease in the opposite lung and other organs. I cannot feel that the separation of adherent pleura, apart from well-defined bands, by surgical means, is at all a sensible proposition, and fortunately there appear to be other possibilities.

Stripping the Costal Pleura: Tuffier's Operation.—Just a year ago I got Mr. Romanis to strip the parietal pleura from the endothoracic fascia over the apex (apicolysis) in a private patient who suffered with a bleeding cavity, and to pack the resulting space with solid paraffin. I was so much impressed on this occasion with the ease with which the parietal pleura stripped, and with the comparative mildness of the operation, done under gas and oxygen and without rib resection, that I felt encouraged to try it in other cases where adherent pleura prevented the production of pneumothorax. Not long after this I came upon a paper by Rieckenburg, working under Ulrici at Sommerfeld, in which he describes two cases of adherent lung where the costal pleura was stripped from the chest wall, and a pneumothorax maintained outside it. He points out the value of the double covering over large cavities in diminishing the danger of perforation, and notes that the raw pleural surface in healing contracts down and prevents further expansion of the lung. The cavity holds gas only under low pressures at first, but eventually it becomes effectively "gas-tight." Encouraged by the possibility this offered, I asked Mr. Romanis in January last to strip the whole costal pleura in a case eminently suitable for pneumothorax, but with total adhesion of the pleural surfaces. The patient had chronic disease of the whole right lung with cavitation, and ran fever to 100.5° in spite of prolonged rest. The left lung was an excellent organ. The chest was opened through the third space, and the pleura separated with the hand over all but the inner surface of the lung. Ample room for insertion of the hand between the ribs was obtained by strong retraction, and the pleura stripped with the greatest ease, but the lung collapsed little as it was solid with disease. The operation lasted but twenty minutes, and was followed by very little shock or reaction. It was realized that the absorption of air would be rapid, but I thought a week could be left before the refill. Most unfortunately, however, the patient only came into my hands again after an interval of twelve days, and by then all the air was found absorbed and the lung re-expanded. It would be wiser, I think, in such a case to leave a small opening to the outer air, and to close this at the end of a week, when refills can be conveniently substituted. The sequel in this case was interesting, for the temporary immobilization of the lung allowed the patient to re-establish tolerance, and the temperature fell to 99° and has remained there; at the same time both lung and general condition have improved. This improvement is reminiscent of some experiences of Schroeder, who found lung fibrosis and recovery to follow a severe traumatic pleurisy in three cases where he attempted, without success, to separate adherent pleural surfaces after a pneumothorax operation by Brauer's open method.

Extrapleural Thoracoplasty.

I have referred to the possibility of thus creating and maintaining an extrapleural pneumothorax because the idea may be new to some of those here present. Of the better recognized means of dealing with adherent pleura, by extrapleural thoracoplasty under local anaesthesia, I shall not here speak, but I hope some others now present may do so. Two admirable papers on this subject by Scandinavian authorities appeared in our journals last year, one in *Tubercle* of April, 1920, by Saugman, dealing with 41 cases, and one by Bull of Christiania in the *Lancet* of October 16th, 1920, with an account of 37 cases. The results appeared to be excellent, and the actual operation mortality small, amounting to but 4 cases in each series.

With regard to all these surgical procedures, it must be noted that operations are not to be lightly undertaken in the subjects of pulmonary tuberculosis; the cases require even more careful selection, especially as regards the condition of the better lung, than they do for mere pneumothorax treatment. Before leaving the subject of adherent pleura I should like to insist that no operative measures must be undertaken for its relief until its actuality is determined by experiment. It might well be supposed that where a great displacement of organs and closing in of ribs has occurred, we are then necessarily dealing with

adherent pleura. But this is by no means the case, as I can illustrate by a radiogram from a patient on whom I induced a pneumothorax some three weeks ago. The heart was entirely in the right chest, and the trachea was drawn over and distorted; and yet the pleural surfaces proved un-adherent, with the result, as would be expected, that the intrapleural pressure had fallen to a very low figure—actually to -27 -25 cm. of water.

Pneumothorax treatment is a big subject, because it involves so many possibilities. What I should like finally to insist on here is the comparative narrowness of its indications, but its striking hopefulness within these limits. All is possible to a case of unilateral, or practically unilateral disease, if only we are sufficiently persistent. It is for that reason that I have wandered to-day into the byways of surgical interference, feeling that in these cases adherent pleura is no excuse for folding our hands and giving in. The patient with one lung has a good fighting chance if only our skill and resourcefulness suffice to discover for him the road to victory.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE DESTRUCTION OF BACILLI BY ELECTRICITY.

In 1915 I started some experiments for the destruction of bacteria by electricity. Pus from a streptococcal abscess was collected in a sterile copper vessel; cultivations on agar yielded a virulent streptococcus. After passing a continuous electric current of 100 milliamperes through the pus for an hour no growth was obtained on agar, but at the bottom of the copper vessel I found a deposit of copper salts sufficient to kill the most virulent streptococcus.

I next tried an electric bath with a carbon pole. I had a patient with a very bad septic forearm, which did not improve with free drainage and antiseptic treatment. I obtained a large porcelain arm bath, filled it with 10 per cent. saline solution, and put one carbon pole at one end of the bath; I made the patient's septic arm the other pole by attaching a zinc plate to his shoulder and allowing him to rest the limb in the warm saline solution. I now passed 80 milliamperes continuous current through the bath and left the arm in it for half an hour. The following day the arm looked very much cleaner and the granulations much healthier. Each day it improved, and within about ten days with daily baths it was almost healed. I discussed the treatment with my colleagues, and we agreed that in all probability the improvement was due to free chlorine gas, which was being liberated by the electric current passing through the saline solution. I was, however, struck by the rapid growth of healthy granulation tissue, which I was convinced was stimulated by the current.

From 1917 to 1919 I continued my observations at the Norfolk and Norwich Hospital, and there treated a number of gunshot wounds with septic sinuses by means of copper sulphate ionization. The sinus was cleaned out and filled with a 1 per cent. solution of copper sulphate. A copper rod was then put down the sinus and a zinc pad placed on the patient's back. The two poles were connected respectively to the anode and cathode of a galvanic battery and a constant current of about 8 milliamperes passed through for about fifteen minutes daily. The rapid healing of the wound was marked by the rapid growth of granulation tissue.

In an attempt to prove that the electric current actually played a part in the destruction of organisms I constructed an apparatus by which the current passed through some pus, but the poles were not in it. By this means the gas given off at the pole could not play a part in the destruction. I obtained a glass vessel, divided into three compartments by plates which would conduct the current. I placed some pus laden with *Staphylococcus aureus* in the middle compartment and the positive pole into one and the negative pole into the other of the two remaining compartments, which were filled with normal saline. A current of 50 milliamperes was then passed through for half an hour at 70° F. By incubation on agar for eighteen hours a very small growth of *Staphylococcus aureus* was obtained. The current was allowed to continue running

through the pus for another hour, at the end of which time a further culture was taken and after forty eight hours' incubation no growth could be seen on agar.

In 1915 I introduced into the out-patient department of this hospital electric baths for sepsis, and they have been used daily ever since with success.

Recently I have tried the same experiment with pus containing *B. coli*, and found it took a current of 80 milliamperes for one hour to kill the organisms. Based on the results of my recent investigations I am convinced that in introducing electric baths to combat sepsis I was not only introducing a means of stimulating granulation tissue and of cleaning the wound but an actual means of destroying the organisms infecting it.

For valuable help in examining the cultures and for advice on many points I am indebted to Dr. H. M. Galt, pathologist to this hospital.

County Hospital

ENTERO-COLIC INTUSSUSCEPTION IN AN ADULT.

W. B., a pale, thin man aged 46, who for the previous four months had been subject to occasional abdominal discomfort but who had otherwise always enjoyed good health, was suddenly seized with severe abdominal pain at 7 a.m. on February 16th, 1920. The pain was intermittent, of increasing severity, and accompanied by retching and occasional vomiting. Shortly after the onset of symptoms the bowels were twice moved and flatus passed.

When first seen, at noon, a rounded, prominent swelling, almost as large as a coconut, was visible in the right iliac region: it was dull on percussion and tender on palpation. The area of greatest tenderness as also of pain, however, was below the right costal margin and in the epigastrium.

His wife volunteered the statement that during a paroxysm of pain, whilst pressing on his abdomen to ease him, she heard a "click," and immediately afterwards discovered the swelling. He was sent to the Victoria Cottage Hospital, Woking. When admitted half an hour later he was collapsed; the temperature was 96.4° and the pulse 64.

Operation.

At 2 p.m. the abdomen was opened through the right rectus sheath; enormously distended and congested large bowel exposed; tracing this in both directions it was found that the ascending colon, as far as the hepatic flexure, the caecum, and about 6 in. to 8 in. of ileum were distended by intussuscepted small bowel. At the apex of the intussusception an oval mass about 2 in. long could be felt, suggestive of a polypus. The intussusception being irreducible, and total excision, owing to the patient's condition, holding out little prospect of success, the ileum above the intussusception was laterally anastomosed to the transverse colon and the abdomen closed. He had only slight post-anaesthetic vomiting.

After-History.

Next morning he complained of a good deal of abdominal pain, nausea, and frequent hiccough, and became faint when moved. The temperature was 100.2° and the pulse 110.

On February 18th the temperature was 99.6° and the pulse 76; there was some increasing abdominal distension. A turpentine enema was followed by severe collapse; the motion consisted of altered blood. On the next day the bowels had moved several times in response to repeated doses of magnesium sulphate and the general condition was improved. The temperature was 100.4° and the pulse 84. From this time onwards the patient's condition steadily improved; pain, nausea, and hiccough gradually subsided; the bowels were moved daily; the appetite returned and the pulse improved, but the temperature remained constantly between 99° and 100°. On February 26th he complained of severe gripping pains, and the following morning had desire to go to stool and passed the entire intussusception. The temperature fell to normal five days later and he made an uninterrupted recovery. He was discharged from the hospital on March 23rd and has remained in excellent health since.

Owing to advanced decomposition it was not possible to make a satisfactory examination of the intussusception. It was about 18 in. in length, the lower end (apex) apparently terminating blindly and containing thick (faecal) material. No tumour was detected.

The appearance of the specimen and the distance of the starting-point from the caecum suggest that a Meckel's

diverticulum may possibly have been the cause of the intussusception. That it was entirely irreducible seven hours after onset was, no doubt, due to the large amount of mesentery contained. The comparatively slight constitutional disturbance after the first few days is noteworthy.

I am indebted to Dr. F. M. Haig, who administered the anaesthetic, and to Dr. F. E. A. Colby, who assisted me in the operation.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

LEEDS DIVISION.

A successful meeting of the Leeds Division was held in the Leeds Township Infirmary on May 19th. In addition to the ordinary business, papers were read and cases and specimens were shown.

Graphic Methods in Cardiac Diagnosis.

Dr. T. WARDLOR GRIFFITH gave a lantern demonstration to show the use of the graphic methods of studying affections of the heart. At the outset he emphasized the view that all the more recent methods, such as the use of the polygraph and of the electro-cardiograph, should be regarded as supplementary to and not as superseding the ordinary methods of examination. The more he used these instruments the more he found he was able to dispense with their use. It was, however, owing to the researches of a large body of workers, using these instruments, that the knowledge of cardiac disease and of cardiac affections had advanced. There were many men who with great facility made an accurate diagnosis of fibrillation of the auricle on the recognition of a non-rhythmical action of the heart, and who forgot, or seemed to forget, that their ability to do so depended entirely upon the work of Sir James Mackenzie, Dr. Thomas Lewis, and those who, like Professor Cushny, had paved the way by experiments on animals.

In the course of his demonstration Dr. Griffith dealt with those temporary interferences with auriculo ventricular conductivity which sometimes occurred in pneumonia, and gave an account of one case in which some impairment of conductivity was accentuated by the use of digitalis, a drug which, however, had probably saved the life of the patient. Another instance was given of a lad with impaired conductivity, in whose case the impairment was abolished by the use of atropine, only to return in a few hours, but in which conductivity was found to be normal at the end of two years. Examples of different degrees of block leading up to complete disassociation were shown.

Leucocytic Changes in Hodgkin's Disease.

Professor STEWART read a paper on the leucocytic changes in Hodgkin's disease and their diagnostic significance. He said that the leucocytic count in Hodgkin's disease was very variable, not only in different cases, but in the same case at different times. Deviations from the normal were most marked in acute and subacute cases. There were three chief types of leucocytic changes—in order of frequency: (1) a neutrophil leucocytosis, relative and absolute; (2) a relative and absolute increase of the large mononuclear cells, not lymphocytes, especially of the transitional type; (3) a relative and absolute eosinophilia. Any one of these three, if well marked, was of some value in the differential diagnosis of a suspected case of Hodgkin's disease, but No. 2, a large mononucleosis, mainly of transitional type, was the only one on which much reliance could be placed. In 8 recent cases in which the diagnosis of Hodgkin's disease was established by histological examination of an excised gland or glands, 3 showed this large mononucleosis, varying from 19 to 33 per cent. (absolute figures, 1,430 to 3,370 per cubic millimetre). The normal figures for large mononuclears (including transitionals) might be taken as from 4 to 10 per cent., or about 240 to 900 per cubic millimetre in absolute figures. Two other cases showed a high neutrophil leucocytosis (20,000, with 85 per cent. polymorphs; and 33,000, with 89 per cent. polymorphs). In a third case there was a terminal relative neutrophilia (9,000 leucocytes, with 96 per cent.

polymorphs). In none of the 8 cases was there a blood eosinophilia, even when the glands were overrun by these cells, as was the case in several. Other observers (Peyzer, Tonycopo, etc.) had recorded cases in which a general eosinophilia was present. An absolute lymphocytosis was quite exceptional, although there might be a relative excess of these cells when, as not infrequently happened, a leucopenia existed. While the examinations of the blood might therefore, in certain cases, aid in the diagnosis of Hodgkin's disease, the excision and microscopic examination of a gland still remained the only thoroughly reliable method of establishing the diagnosis.

Post-Operative X Rays in Breast Cancer.

Dr. ROWDEN read a paper on the post-operative x-ray prophylactic treatment of malignant disease of the breast. He said that the operation for malignant disease of the breast was generally disappointing, owing to the large percentage of recurrences locally, and mostly within twelve months: with post-operative x-ray treatment local recurrence was unusual; without x-ray treatment death was not usual without local recurrence. Dr. Rowden expressed the opinion that x-ray treatment of malignant breast without operation was quite unjustifiable, nor was x-ray treatment immediately before operation justifiable. Radiation had a marked paralytic effect on growing and young cells, but the rays were rapidly filtered out in passing through tissues, and therefore could not affect a growing cell deeply placed without injuring the overlying tissues. After operation the condition was more favourable for the use of x-rays as the cancer cells are near the surface. A short and active treatment was advisable. Dr. Rowden suggested to the surgeon: (1) Early operation; (2) to leave no raw surface—a raw surface appearing to favour local recurrence; (3) to order the rays two weeks after the operation, six to eight weeks after operation was too late. Dr. Rowden gave the following statistics of 21 cases with completed treatment up to three years ago since 1909. Of these cases there has been only one local recurrence five years after operation.

15 are living; all well except the case of recurrence.

5 have died:

One 9 years after operation—disease in mediastinum;

One 16 months after operation—disease in spine;

One 17 months after operation—disease in mediastinum;

One 2½ years after operation—mediastinum and neck;

One 2½ years after operation—mediastinum and neck.

1 cannot be traced.

Dr. ALLAN showed pathological and surgical specimens, also some surgical cases.

Reports of Societies.

ARTIFICIAL PNEUMOTHORAX.

At the meeting of the Section of Medicine of the Royal Society of Medicine, on May 24th, Dr. A. F. VOELCKER presiding, Dr. CLIVE RIVIERE read a paper on artificial pneumothorax, which is printed in full at page 810.

In the course of the discussion following the paper Sir JAMES KINGSTON FOWLER described the first case in his experience in which artificial pneumothorax was performed for the relief of haemoptysis. This was in 1885, when a patient was admitted to Middlesex Hospital, and within thirty-one days had twenty-one severe attacks of haemoptysis, and brought up 196 ounces of blood. It was then decided to make an incision in the thorax and induce, if possible, collapse of the lung by this method. The operation was performed, and the lower lobe collapsed to some extent. There were two attacks of haemoptysis subsequently during the five days for which the patient lived, and about 10 ounces of blood were brought up. It was found that there were adhesions which prevented complete collapse. It was quite impossible to have saved the man's life; but, despite the imperfect methods then employed, he thought it might be claimed that even at that time there was a measure of success. In the first place, there was very little haemorrhage after the operation compared with the great amount that had taken place

before, and the lung underwent a certain degree of collapse, which would have been complete had it not been for adhesions. He considered that the introduction of artificial pneumothorax was one of the great advances in treatment within his long experience.

Dr. VERE PEARSON thought that there was still too much diffidence in advising or undertaking this operation. Experience had taught him that it was quite impossible to tell beforehand with the help of x-rays or any method of examination whether adhesions were present which were going to prevent pneumothorax. He now abandoned the procedure if he failed after two sittings at each of which he punctured perhaps three times. He had also given up attempting, in cases with a good many adhesions, to break these down in the early stages by increasing the pressure; such cases failed to do well. It was in one such case that he came across an indication of gas embolism. The other bugbear was pleural reflex; he had had two cases with very alarming symptoms, which he put down to that condition. He found that the liability to the outpouring of fluid did not vary materially whether the pneumothorax was complete or partial. In conclusion, he felt that there was a hiatus between the surgeon and the physician which ought to be bridged.

Dr. NEVILLE COX, speaking from his experience at Midhurst, also appealed for more help from competent surgeons, and said that every large sanatorium should have a properly equipped operating theatre with a surgeon prepared to deal with these cases. He instanced also two points of technique—the first, that the use of a pointed needle for the first injection should be avoided, for it must be a matter of luck rather than skill if there was not a puncture of the lung; the second, the inadvisability of using tuberculin in after-treatment.

Dr. DONALD HALL was convinced of the great value of the treatment. There must be in this country hundreds of cases left to die because it was denied. The treatment did not receive from the profession as a whole the recognition which was its due. For this neglect there might be several reasons or excuses, among them ignorance, lack of material, timidity, and the strain which the treatment imposed on patient and physician. Cases must be selected with the greatest care, but he thought that for pulmonary tuberculosis with excavation artificial pneumothorax at present held the field.

Dr. JANE WALKER said that at the East Anglian Sanatorium this treatment had been applied in 117 cases, and there had been failure to produce pneumothorax in about 10 per cent. A certain amount of mischief in the other lung was not a contraindication, and in a large number of cases, with the general improvement in the patient's condition, a diminution of the signs in the other lung had taken place. So far there had been no serious accident, except that occasionally a vein had been punctured. The simplest possible form of apparatus was used, and the only modification which had been made since this treatment was first practised was that air instead of nitrogen was used. She thought that the time had now come to consider whether this method of treatment should not be applied to cases before they became so severely ill. In all these cases the artificial pneumothorax was induced as the last hope, and although the percentage of recoveries was comparatively low, life had been made more bearable for many.

Dr. C. S. BURRELL thought that the spacing of the refills was of the greatest importance. Unless they took each case individually and refilled at intervals which were found suitable in each instance, they were not likely to be successful. He agreed with the method of giving a small quantity of air at frequent intervals, the maximum interval being a month.

CAUSES, PROGNOSIS, AND TREATMENT OF STERILITY.

At the meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine held on May 5th, with Professor HENRY BRIGGS, the President, in the chair, Dr. ARTHUR GILES opened a discussion on the causes, prognosis, and treatment of sterility. He said that he proposed to touch on two of the general aspects of the subject—the prevalence of sterility, and the responsibility of the male partner—and then to sketch out three types of sterility in women, viewed from the standpoint of pro-

gnosis and treatment—namely, (a) inevitable and incurable sterility, (b) functional sterility, and (c) conditions that caused or favoured sterility, but allowed of treatment. Estimates of the proportion of infertile marriages varied widely with different authors and in different countries. Some, like Frank and Burdach, placed it as low as 2 per cent.; others as high as 20 per cent. He had endeavoured to form an estimate from his case papers, with the result that he thought it was a sound deduction that the proportion of sterile marriages in this country was well below 15 per cent. Dependence upon figures given by various writers was weakened by the fact that in some statistics stillbirths were taken into account while in others they were not. Of published estimates he was disposed to regard those of Simpson as being nearest to the truth; he found the proportion of unfruitful marriages to be 10.9 per cent. in village communities, and 16.3 per cent. in families of the aristocracy. The ratio was probably higher in towns than in the country.

It was not sufficiently realized that in many cases the woman was not at fault. Estimates again varied widely as to the proportion of cases in which the husband was to blame. The actual figures were of less consequence than appreciation of the fact that in a childless marriage the woman might not be at fault, because it had an important practical corollary that in doubtful cases the wife should not be assumed to be responsible and submitted to operative procedures without obtaining definite evidence that the husband was healthy. It would be all the easier to recognize the cases of incurable sterility if the conditions necessary for successful impregnation were remembered. They were: On the man's part, ability to deposit healthy seminal fluid in contact with the os externum cervicis; on the woman's part, (1) ability to receive this fluid in contact with the cervix; (2) such a healthy condition of uterus, tubes and ovaries as would enable the spermatozoa to travel up to meet the ovum; (3) the production and discharge of healthy ova; (4) such a healthy condition of the uterus as would enable it to harbour the fertilized ovum.

1. The conditions under this head that caused sterility were absence of the vagina and want of communication between the vagina and the uterus. It might be necessary to undertake a dissection of the parts before the point could be cleared up. When the vagina was absent the question might arise whether an artificial one should be made. From the point of view of sterility the procedure would be hopeless. Whether it should be done in order to make married life possible was another matter.

2. This condition was unfulfilled in the case of absence or marked under-development of the uterus, congenital atresia of the tubes, and occlusion of the tubal channel by inflammation. Pyosalpinx, which was due to gonorrhoea in about 95 per cent. of the cases and to tuberculosis or *Bacillus coli* infection in the remainder, certainly caused incurable sterility.

3. For conception to be possible the ovary must produce healthy ova, but it was very difficult to say when it was not doing so. Age and the action of 2 days led to ovarian atrophy, and it might be presumed that at when this atrophy had come about ovulation ceased. But there were other conditions that apparently interfered with normal ovulation—for example, anaemia, chronic taking of drugs such as morphine, certain febrile conditions and some nerve conditions, including pituitary disease. Obesity might come into this category. The factors that disturb normal ovulation, or the influence, if any, of internal secretions on ovulation, were unknown. It would not be unreasonable to assume that the physical and chemical causes of ineffective ovulation acted by interfering with the nutrition of the germ cells.

4. This condition was not strictly one upon which successful impregnation depended, since failure therein led to miscarriage, not to sterility. From this point of view, however, the cases that were hopeless and incurable were those of uterine tuberculosis, carcinoma and sarcoma of the body of the uterus, and uterine fibrosis.

When a childless woman who had been married for some years gave a history of regular menstruation without undue loss or unusual pain, and, on examination, the pelvic organs appeared to be normal, the case might be regarded as one of functional sterility. There were then several possibilities to be considered. Complete intercourse might not have taken place; or the husband might be at fault, suffering from azoospermia or from a deficient vitality of the spermatozoa; or, thirdly, it might be an instance of "sexual incompatibility." Of the conditions that caused or favoured sterility but allowed of treatment, some prevented normal intercourse—such as atresia of the vaginal orifice, stenosis of the vagina and rigidity of the hymen,

dyspareunia and vaginismus, and tumours encroaching on the vagina—all of these were more or less amenable to surgical treatment. Inasmuch as prolapse and procidentia were usually the sequel of child-bearing, they were the cause of secondary rather than of primary sterility. The obstacle to intercourse was mechanical, and treatment gave a good prognosis. Conditions that allowed intercourse but interfered with ascent of the spermatozoa included under-development of the uterus; in this the prognosis depended mainly on the patient's age; if she was not much over 20, it might be an instance of delayed rather than of arrested development. The presence of either antelexion of the uterus or stenosis of the os externum must be regarded as very unfavourable to conception; but it could not be said that conception was impossible, and, from the point of view of prognosis following treatment, these were among the most satisfactory cases. Retroversion of the uterus, again, must be considered as unfavourable to conception, but not as definitely preventing it. In atresia of the os externum prognosis was hopeless without treatment, and not very good with it; but, nevertheless, an attempt should be made to restore the patency of the canal. Under the heading of polypus in the uterine canal might be included fibroid and mucous polypi and submucous fibroid, and in nearly every case the condition could be cured by operation. Endometritis sometimes caused absolute sterility by preventing conception, probably through the injurious effect of the discharge on the virility of the spermatozoa.

It was nearly certain that in cases of mild salpingitis without occlusion of the tubal ostia, conception could take place, and in all probability the sequel was often a tubal pregnancy. It might be supposed, however, that uterine pregnancy also followed, for cases were familiar in which child-bed fever was apparently due to the lighting up of a latent infection of the tubes. Obviously when salpingitis with occlusion was present conception was impossible; but within certain limits it could be remedied by operation—namely, in those cases in which there had not been extensive suppurative or damage to the tubes. An artificial ostium could be contrived by making an incision in the tube, near the ovary, and oversewing the edges, to prevent the opening from closing up again.

Dr. R. A. GIBBONS said that the average fertility of fertile marriages during the whole of the child-bearing period was ten. As the result of a voluntary confidential census among intellectuals, it was found that of 120 marriages, 107 were "limited," and that the average number of children of each marriage was considerably under two. Congenital sterility was rare, both in men and women; but the number of children in each family had steadily declined in recent years. He had known women who had started married life with a determination to avoid conception, and later had done all they could to cause conception and had failed. There were others who, having had one child, had resolved to have no more; and when, later on, they changed their minds, they were bitterly disappointed that all their efforts to procure a second child had had no result. The majority of men did not know the harm which might follow the use of preventives, especially to the nervous system of women with normal sexual feelings.

Mr. KENNETH WALKER had examined a number of husbands of women patients of Dr. Donaldson. In about 15 per cent. of the cases it could be stated that the husband was sterile, and in a still larger number something abnormal could be detected in the genitalia; there was either oligospermia or what might be regarded as an undue number of degenerate forms of spermatozoa, or signs of inflammatory trouble in the testes, prostate, or vesicles. If the vesicles of a rat were removed he remained fertile; the same was true after excision of the prostate. But if he were deprived of both prostate and vesicles he was sterile. Mr. Walker believed this to be confirmed by clinical experience, and it showed that the mere presence of spermatozoa in the semen did not prove that the male was beyond suspicion.

Dr. HERBERT SPENCER had given up dilating the uterus for sterility for nearly twenty years in favour of Pozzi's operation, and he had seen one case in which an under-developed uterus, which had been dilated unsuccessfully, had conceived at once, after seven years' sterile life, after performance of Pozzi's operation. He corroborated Dr. Gibbons' remarks on the frequent use of preventives and

their effect in causing permanent sterility. This was especially the case with quinine pessaries.

Dr. Louise McIlroy said that the work of the future must go upon physiological and biological lines, and the effect of the internal secretory organs upon the reproductive functions must be studied further. The ovum should be looked upon as a temporary ductless gland; and in cases of repeated abortion for which no cause could be found there was sometimes evidence of the inhibitory action of the endocrines upon the growth of the ovum. Among cattle it was found that the massage of an ovary containing a persistent corpus luteum favoured fertilization in previously sterile animals. Dr. McIlroy was of the opinion that the Section should utter a protest against the growing use of contraceptive pessaries. Efforts to prevent the satisfaction of the maternal instinct when the sex instinct was stimulated at the same time were no doubt accountable for many gynaecological conditions and neuroses.

Dr. FAIRBAIN felt that the cases that caused most difficulty were those without physical signs or mechanical causes; and he agreed with Professor Louise McIlroy that more biochemical research into the causes of sterility was needed.

Reviews.

CLINICAL DISORDERS OF THE HEART BEAT.

THAT within nine years, more than half of these disturbed by the war, no fewer than five editions of Dr. THOMAS LEWIS's *Clinical Disorders of the Heart Beat*¹ have appeared bears eloquent testimony to the profession's opinion of the value of this clear statement of a difficult subject. It is surrounded, for the ordinary man, by a certain amount, if not of mystery, at least of the unknown in connexion with the electro-cardiograph and the polygraph, with which, as the means of investigation, he is familiar in name but not in deed. Dr. Lewis has given in full detail the evidence on which the modern conception of cardiac disorders and disease is based in many papers and other books, especially *The Mechanism and Graphic Registration of the Heart Beat* (reviewed in the BRITISH MEDICAL JOURNAL of July 31st, 1920, p. 166). Here, in a convenient form, he lucidly sets forth the practical conclusions required by the practitioner for his daily work.

In reply to the question, In what degree is an acquaintance with the graphic method essential or expedient in the routine of practice? Dr. Lewis answers that, though the acquisition of the necessary manipulative skill and experience demanded by the taking and interpretation of such records will often entail too much expenditure of time and energy to repay the practitioner or his patient, the practitioner should be thoroughly conversant with the new knowledge thus put within his reach. With this information in mind there are few important disorders of the heart which the unaided and practised senses cannot recognize. This handbook supplies this information by giving an account of the clinical picture, prognosis, and treatment of the seven forms of cardiac disorder—namely, sinus arrhythmia, heart-block, premature contractions or extra-systoles, simple paroxysmal tachycardia, auricular flutter, auricular fibrillation, and alternation of the heart—so clearly and authoritatively that every practitioner and student should have it in his possession and its teachings in his mind.

THE ENDOCRINE ORGANS IN GYNAECOLOGY.

The Endocrines,² by Professor BANDLER, is one of those books whose conversational if attractive title is a little misleading, for the work is not a comprehensive study of the subject so much as a somewhat limited consideration of the ductless glands from the point of view mainly of the gynaecologist. Written with the author's customary fluency, it is pleasant reading, and its perusal will undoubtedly repay those who foresee in the subject a vast

field for much work, and, it is to be hoped, successful and beneficent employment in the near future of gynaecology. The structure of the book suggests that it has been composed in part by the conglomeration of several separate papers. This may, perhaps, be the explanation of an unnecessary discursiveness on subjects which are not always obviously germane to the main thesis.

Professor Bandler begins by a long discussion of heredity and environment, written in a most grandfatherly style, in the course of which he makes many interesting observations on the emotions and characters of childhood, adolescence and maturity, and gives much prudent advice on education and upbringing. In a subsequent chapter he is led to emphasize the study of the inheritance of tendencies to aberration in the inter-relationship of the ductless glands; the recognition of such tendencies will, it is thought, provide the physician with a fund of knowledge at may well prove a powerful and in his dealings with his patients. A brief systematic study of the different individual glands and their functions prefaces a chapter on the particular bearings of the different hormones on gynaecological conditions, especially upon puberty, the menopause, and menstrual disorders. The possible influence of the internal secretions on the causes of sterility forms a peculiarly interesting chapter. Then follow sections indicating the part played by the secretions of the endocrine glands in connexion with the emotions and instincts, phobias, and mental and nervous defects and deficiencies. Lastly, there is a chapter on the all essential balance of the different secretions. The later part of the book deals with endocrine therapy, with methods of investigations into endocrine defects, and with the author's own case records.

Altogether Professor Bandler has produced a most interesting volume, and while it may be felt that several of the views he strenuously upholds still await confirmation, not to mention proof, it may well be that for this very reason his book will be found the more stimulating to thought, and probably also to methods of treatment, some of which are still in large measure empirical. It is impossible to read such a book as this without feeling that, while we are certainly on the verge of great discoveries, we are just as likely to be entering on a period when potent hormones will be widely employed as drugs with the same lack of discrimination as characterizes vaccine therapy in many hands—guided, it may be, more often by the seductive advertisements of the manufacturing chemist than by knowledge. But the discovery of the truth is never to be hustled. There are to be found in Professor Bandler's pages warnings against a merely ignorant optimism, but let not his readers be carried away too completely by the infection of his enthusiasm when, for example, he breaks out into prophecy. "In five years there will be few mental defectives (new), few insane (new), few tumours (new), few cancers (new), few diabetes (new). Since they are due to endocrine aberrations they will be corrected in their earliest stages by endocrines. When the next war comes soldiers going over the top will not be given alcohol; they will be given endocrine cocktails, and adrenal cortex will be an important ingredient." His experience as an obstetrician should have made the author particularly chary of committing himself to prophecy. But perhaps this is a mental by-product of a "dry" America!

THE TREATMENT OF THE NEUROSES.

Dr. ERNEST JONES devotes the major portion of his book on the *Treatment of the Neuroses*³ to an account of hysteria and a critical survey of the various physiological and psychological measures which have been suggested for its treatment. The views developed in this chapter are largely applicable to the psychoneuroses generally, and are here grouped under the one heading of hysteria in order to avoid needless repetitions in dealing with other forms of disorder. The author gives an excellent description of the hysterical personality, and in providing a lengthy summary of the various therapeutic methods of approach he clearly indicates their value and limitations, and has many pertinent criticisms to offer. As an exponent

² *The Endocrines*. By Samuel Wyllis Bandler, M.D., Professor of Gynaecology, P.S. School of Medicine, New York. Philadelphia and London: W. B. Saunders Company. 1920. (Med. 8vo, pp. 491, 35s. net.)

³ *Treatment of the Neuroses*. By Ernest Jones, M.D. Lond., M.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1920. (Demy 8vo, pp. viii+233. 10s. 6d. net.)

of Freudian views in this country. Dr. Jones devotes particular attention to psycho-analysis as a form of treatment, and here becomes a strong partizan rather than a critic.

It is difficult to avoid the reflection that if the author had shown the same critical attitude towards the system he so strenuously supports as he does towards alternative methods of treatment his book would have been a contribution to medicine of considerably greater value. He is much less convincing as an advocate than as a critic, and his attitude towards his own subject is dogmatic rather than persuasive. Especially is it to be regretted that the author still finds it necessary to deny the possibility of an objective standpoint on the part of the opponents of his doctrines, and that, in advocating his views, he is unable to avoid a discussion of the mental state of those who find themselves unable to agree with him. Can it be that the select coterie of Freudian adherents are the sole exponents of a scientific attitude towards the problems of mental life? The method upon which Dr. Jones bases his views would seem to involve the interpretation of phenomena on the basis of a system of beliefs already held by the observer to an extent which would not be considered permissible in any other branch of science, for he writes as follows:

"As was indicated above, the material gained in these various ways is then submitted to a process of elaboration and elucidation, whereby the same characteristics in different parts are brought together, correlations established, obscurities clarified, and an underlying co-mplexion and meanings may be plain. The resulting interpretations are made use of to direct the patient's attention towards the more hidden material for which they furnish clues. The technique of psycho-analysis comprises innumerable minor rules dealing with the interpreting of material, and with the difficult question of how to decide the right moment for conveying the interpretations to the patient." (Page 126; italics ours.)

Surely the scientific validity of this method is at least open to question, and Dr. Jones should not be surprised if many psychologists hesitate to accept a view of mental life and development based upon a mode of investigation in which suggestion is admitted, and can, indeed, scarcely be avoided.

A STANDARDIZED BINET-SIMON SCALE.

The growth of the use of mental tests on the Binet-Simon lines both in schools and in courts of justice, has suggested the desirability of standardizing these tests so that the results obtained in the investigation of mentality may be to some extent interchangeable and of value in communication between those interested in a given case. Hitherto no manual has appeared which embodied a uniform method of dealing with such questions as the following: With what tests should the examiner begin? Which of two alternative questions should first be employed in a given case? Under what conditions may a test be repeated? A few years ago a series of experimental investigations in the testing of mentality were instituted by Mr. NORBERT J. MELVILLE of Philadelphia. The results of this research are embodied in a book entitled *Standard Method of Testing Juvenile Mentality by the Binet-Simon Scale and the Porteus Scale*.⁴ The conduct of the investigation necessitated the training and supervision of several hundred co-workers and the valuation of the results of some thousands Binet tests. The work was done in a number of public schools in New York, Princeton, and Philadelphia. The results of Binet tests, it is pointed out, do not always tally with the known state of scholarship. The Binet scale was expressly designed so that it should not be a direct test of school knowledge but of juvenile mental development. The scale determines how much an individual has profited from some typical forms of experience and training which the majority of children in civilized countries undergo, not only in school but also in the home and in the playground. The book is divided into two parts. The first deals with the nature and scope of the tests, their manner and order of usage, and the materials to be employed. The second gives a series of standardized tests for each age. The tests are

actually given in the pages of the book in question, drawings, and coloured diagrams. These pages are underdone so that reference is facilitated.

In the introduction, written by Dr. William Healy, there is a necessary warning that people of sound training, and good judgement are needed to use these methods for the better study of human beings.

A MEDICAL TEXTBOOK FOR NURSES.

Nurses are charged with the responsibility of carrying out the orders of the medical man, and it is claimed by Dr. FORTESCUE-BRICKDALE in his *Textbook of Pharmacology and Medical Treatment for Nurses*,⁵ that this function will be performed with more accuracy and intelligence the more nurses appreciate the ideas which underlie their instructions. With this principle we agree.

The book is divided into two parts. Part I deals with pharmacology, and in very simple and concise language gives an account of the action of the ordinary medicinal remedies. Technical terms are for the most part avoided, and no doses are given. It is a good feature of the book that in the discussion of any drug or group of drugs the various proprietary remedies which have come into use, and which are copies or slight modifications of well known drugs, are described. This is of some importance, as in these days the nurse as well as the medical man is circled by the vendors of proprietary remedies, and her education affords her no means of forming an opinion. It might have been well had the writer taken the opportunity of impressing on his readers the fact that proprietary remedies, with few exceptions, are either drugs in the experimental stage or mere commercial speculations, and to point out that when a drug is proved to be of value it is included in the *British Pharmacopoeia*.

The book is well illustrated by anatomical diagrams, for example of the heart when digitalis is discussed; by pictures of plants, sometimes coloured, and by tracings which show the action of drugs clearly, and are easily understood. This part also contains an account of vaccine and serum treatment, and of organo-therapy. The author has explained in simple language the foundation of medical treatment, and we have few criticisms to offer. Perhaps he deals with ions more fully than is necessary, and opinions, even if they exist, are of no importance to nurses.

Part II deals with treatment, but wisely contains no clinical or pathological details. A nurse ought to know the nature of the disease from which her patient is suffering, and be familiar with the routine methods of treatment, and the object of the present part is to explain the rationale of this treatment. The diseases are arranged according to organs, such as diseases of the urinary organs, respiratory system, fevers, and so on, and special stress is laid on that portion of the treatment which the nurse is expected to carry out. The illustrations in this part also are good and helpful. It is a pity that more is not said on methods of administering remedies, the masking of tastes, preparing and administering hypodermic injections and details of disinfection, and less on the medicinal treatment of symptoms such as, for example, those that may occur in locomotor ataxy. It is doubtful whether anyone without a knowledge of physics could understand Appendix III, which gives the scientific basis of radio-therapy. The book is admirably printed in large type, and is very free from errors. It is the first book of its kind, and we can whole heartedly recommend it to every one who is taking up nursing as a profession.

A SYNOPSIS OF PHYSIOLOGY.

Physiology,⁶ by Dr. FRANKCON ROBERTS, in the Students' Synopsis Series, is a small book "definitely addressed to those who are already acquainted with the elements of the subject, and is intended to supplement the larger textbooks." It is not a mere cram book or a boiled down edition of the larger textbooks, it is a synopsis in which the salient features of the subject are well brought out, and, in the case of the chapter on intermediate metabolism,

⁴ *Standard Method of Testing Juvenile Mentality by the Binet-Simon Scale and the Porteus Scale of Performance Tests*. By NORBERT J. MELVILLE. Introduction by William Healy, M.D., Psychopathic Institute Chicago. Second enlarged edition. London: J. R. Applecott Co. 1921. (Cr. 8vo, pp 162; illustrated 12s. 6d net)

⁵ *Textbook of Pharmacology and Medical Treatment for Nurses*. By J. V. Fortescue-Brickdale. London: Henry Frowde, and Hodder and Stoughton. 1920. (Double Roy 8vo, pp 455, 77 figures, 5 plates. 25s net)

⁶ *Physiology*. By Frankcon Roberts. Students' Synopsis Series. London: J. and A. Churchill. 1920. (Cr. 8vo, pp 331; 75 figures. 15s net)

very well presented. The arrangement is good and logical, and only a few actual errors have been detected. The illustrations on the whole have been well selected, and do illustrate the points intended.

A GUIDE TO NEUROLOGICAL DIAGNOSIS.

The guide to neurological diagnosis, written by Dr. K. SINGER, and published in Berlin, is arranged on clinical lines, being divided into chapters on paralysis of peripheral and central origin, disturbances of sensation, conditions of increased and diminished reflex activity, fits, and so on. A certain amount of anatomy and physiology and a modicum of pathology are introduced. A serious drawback is the absence of any really good illustrations or figures in the text. Such figures as do occur cannot be praised, and in this respect the book compares unfavourably with similar British or American publications. We have noticed strange omissions. Thus, in the section devoted to paralysis from spinal cord lesions we find no reference to the experiences of the neurological injuries of war and particularly to the work of Head and Riddoch in this respect. The account given of disturbances of sensation arising from cerebral lesions, again, is altogether inadequate. In a very brief paragraph on the etiology of multiple neuritis no mention is made of acute toxic polyneuritis. The chapter on disturbances of speech follows quite conventional lines, is very short, and hardly adequate for so large a subject.

Diseases of the sympathetic nervous system receive very scant consideration, particularly in view of the large amount of interest the subject has recently aroused. For a book bearing the date 1921 it does not fulfil expectations.

THE CONTRIBUTION OF MEDICINE TO HISTORY.

The influence of variations in the health of kings and ministers and other persons of political importance on the course of events is a department of history which has attracted more attention in France than other countries, probably because for some three centuries that country was an effective autocracy where the state of mind of the ruler—a fit of depression or a spasm of exaltation—might have immediate and serious effects on policy. Interest in the subject and his belief in the influence of breeding and heredity combined to disturb the judgement of Michelet, and sometimes perhaps biased even Taine. It has been a favourite side study with many members of the medical profession in France, and it has been for thirty years the main occupation of Dr. Cabanès of Paris; he is the author of a whole shelf full of very readable books, and the editor of a monthly periodical, the *Chronique Médicale*, which gives hospitality to a multitude of scraps of curious information, mainly biographical, and contains during a year a number of longer articles often of considerable historic interest and importance.

During the winter before last Dr. CABANÈS gave a course of lectures in Brussels; these he has revised, and they are now published in a volume entitled *L'Histoire éclairée par la Clinique*.⁹ Some parts of the volume are more solid fare than the author is accustomed to offer his readers. The earlier chapters are concerned with the importance of science in general to the study of history, and the real subject of the book is only reached when he comes to discuss the help medicine can give to the historian by enabling him in the first place to recognize the mental or bodily disorders, permanent or transitory, of political personages, and, in the second, to appraise correctly the effect of such disturbances on public affairs. Dr. Cabanès gives some examples of the way in which a minute study of details may sometimes suggest probable explanations of peculiarities of conduct that have puzzled contemporaries and historians alike. To one of these we make reference elsewhere. Dr. Cabanès is a judicious guide; he is an enthusiast for his subject, but anxious to make a just estimate of its importance. His final chapter, in which he sums up the lessons he has learnt during the many years he has given to the study of the relation of medicine to history, should be read by professed historians as well as by medical men who take an interest in the philosophy of history or even in its biographical and anecdotal byways.

NOTES ON BOOKS.

TUBERCULOUS salpingitis forms the subject of the most recent fascicule of the *Johns Hopkins Hospital Reports*.⁹ The writer, Dr. J. H. GREENBERG, has made a painstaking study of the 200 cases in the hospital gynaecological records; the conclusions he has been thus enabled to reach are instructive and of particular value on account of the large amount of material on which they are based. The general incidence of the condition amongst 24,000 gynaecological patients was found to be just under 1 per cent.; amongst all forms of salpingitis it accounted for 7.5 per cent. Tubercle bacilli were found in 20 out of 25 cases specially stained for the purpose. Tuberculosis of the uterus was proved to coexist in 45 per cent., but its true coincidence is suggested as being more probably about 72 per cent. Cervical tuberculosis was present in only 3.5 per cent., and vaginal tuberculosis in 0.5 per cent.; peritoneal involvement existed in 63 per cent., and the appendix was found to be tuberculous in 3 per cent. Four cases (2 per cent.) had associated tuberculosis of the urinary tract. The mortality in hospital was 8.5 per cent., and of those operated upon 7.6 per cent. A full bibliography is given. Dr. Greenberg is to be congratulated on a good piece of work, which will be of value for purposes of reference.

In his volume, *De l'Anaphylaxie à l'Immunité*,¹⁰ Professor MAURICE ARTHUS of Lausanne, whose name is so familiar in connexion with Arthus's phenomenon or local gangrene at the site of repeated injections of horse serum into a rabbit, has collected together the results of more than fifty of his papers published on this subject since 1903 and based on 2,500 experiments. This record of devotion to a difficult subject contains in a convenient form Professor Arthus's numerous observations on anaphylaxis, protein poisons, snake poisons, antivenomous serum, and anaphylaxis-immunity. It is a statement of indefatigable experimental research, and acting up to his motto, "beware of theorists and of theories," he refrains from embarking on hypotheses. He finds that in the dog anaphylaxis, both active and passive, is specific, whereas the rabbit is an exceptional animal in that anaphylaxis is not specific. His experiments convince him that the cells of the central nervous system are not directly acted upon by toxic proteins or in anaphylaxis, thus differing from the general opinion as to the production of anaphylactic shock. On the question whether anaphylaxis and immunity are modifications of the same condition or are independent states, he concludes that they are distinct.

The two periodicals *Psychobiology* and the *Journal of Animal Behaviour* have been merged under the new name of *The Journal of Comparative Psychology*.¹¹ The journal will be edited by KNIGHT DUNLAP, Johns Hopkins University, and ROBERT M. YERKES, National Research Council, in association with a number of prominent American psychologists. It will be issued bi-monthly, and the *Behaviour Monographs*, which are issued irregularly, will be continued in connexion with the new journal. Studies which contribute to the knowledge of mental function and behaviour of any organism will be accepted for publication. The new periodical is expressive of the increasing tendency of psychology to develop into an objective science, and it will no doubt furnish contributions of much value to the understanding of animal and human behaviour. The first number (February, 1921) consists of two interesting contributions. John Lynch Ulrich writes a second instalment of his researches on the "Integration of movements in learning in the albino rat," and English Bagby writes on "The psychological effects of oxygen deprivation."

The number of books intended to give the young mother information needed for the preservation of her own health and that of her infant is now very large. Among the best is *Mother and Child*,¹² by Dr. EDWARD P. DAVIS, of Philadelphia. In revising the text for the fourth edition he has taken the opportunity of warning older women against some common fallacies. There are many illustrations, most of them helpful, though the picture of a bassinette looks as though it came from a tradesman's catalogue, and some others might have been omitted without really detracting from the value of the book.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

ANNUAL DINNER.

THE annual dinner of the Federation of Medical and Allied Societies took place at the Café Royal on May 26th. Sir BERKELEY MOYNIHAN, the President of the Federation, was in the chair, and among those present were Dr. Addison, M.P., Sir Alfred Mond, M.P., Lord Dawson of Penn, Lord Queensborough, Viscount Knutsford, Sir George Newman, Sir H. Kingsley Wood, M.P., Dr. Nathan Raw, M.P., Dr. Donald Murray, M.P., Sir Philip Magnus, M.P., and Dr. F. E. Fremantle, M.P. The company numbered just over a hundred, and included representatives of thirty-eight separate societies of the medical and allied professions.

Sir BERKELEY MOYNIHAN, in proposing the health of Dr. Addison, said that the late Minister of Health had been subjected to a considerable amount of criticism, but that was an atmosphere in which politicians thrived. Some of the criticism had been timely, wise, and helpful, some of it had been silly, displaying poverty of imagination and even of invective; and some of it had been malignant, though in the part of the country from which he came he had never discovered any metastatic deposits from that malignant focus. He knew Dr. Addison many years ago when the future statesman was an anatomist. He bitterly regretted that Dr. Addison had deviated—he would not express it in terms of pathological degeneration—towards politics. Had he remained an anatomist he would now have been the first anatomist in the Empire. He wrote a work on the topographical anatomy of the abdominal viscera, especially the gastro-intestinal canal. "I have perhaps as friendly and intimate acquaintance as anybody," said the speaker amid laughter, "with most of the abdominal viscera, and I can assure Dr. Addison that the viscera appreciate very much the work he has done on their behalf. Those who have to teach the topographical anatomy of the abdominal viscera to students to day have to refer to the work of Addison. So far at least anatomy is concerned, Dr. Addison's name is immortal." Dr. Addison's appointment as first Minister of Health (he continued) was received with acclamation by the whole profession. It needed courage to accept the office. It was not incongruous to suggest at that table that there were some present who might well have been thought of in connexion with the post, but he would like to ask them and to ask himself—for the "Gentleman with the Dustet"—had put him in the ideal Cabinet as Minister of Health—if any one of them could have done so much and so well in so short a time. There could be no discordant voice in the profession as to Dr. Addison's aims, even though there might be difference as to his procedures. He had had not only to overcome ignorance, but to fight against the stultifying imperviousness to new ideas. And he had done things which no man would ever be able to change. It had to be remembered, of course, that his plans were conceived in a time of national prodigality, and had to be put into practice in a time of national poverty. But he (Sir Berkeley) would plead with those whose voice had any weight with the people in authority that the last direction in which economies were insisted on should be the broad highway which led to national health. The whole profession owed a great debt to Dr. Addison, who would be astonished if he knew what backing he had from general practitioners. The Federation also owed him a debt because, at the very beginning of its history, he, standing high in the councils of the nation, had pleaded for a united profession. There was a profession of divided counsel and jarring factions; its interests were not necessarily conflicting, but pains seemed to be taken very often to make them so. The speaker concluded with a happy allusion to the rod of Aesculapius, likening Dr. Addison to the god Mercury, who threw his staff among the quarrelling serpents, so that they twined themselves around it henceforth in friendly co-operation.

Dr. ADDISON, in reply, expressed his thanks for the cordiality with which he had been received, and praised the aim of the Federation to bring together the medical and allied professions, and to foster among them a lively interest in public questions. To those who had eyes to see it was clear that, whatever might be the ebb and flow of events, society would seek more and more to enlist the aid of those who could best help it to promote the physical well-being of its members and to prevent avoidable disabilities. The mass of avoidable disability was strikingly revealed during the war, and it was because of this that the dominant purpose of the Ministry of Health, at least in the early stages of its history, must be to develop and

encourage all preventive agencies. In order to do this a long view was necessary. Opportunist spectacular performances were not the function of such a Ministry. He might give many illustrations on this point. The Ministry, for instance, had inaugurated a system whereby assistance was rendered to port sanitary authorities in order to prevent the invasion of post-war pestilence. The total cost of this scheme was £65,000 in this year's estimates. Owing to the vigilance and efficiency of the sanitary authorities the country had been kept free from any such epidemic. This trifling insurance had enabled us to escape a disaster which would have been hundreds of times more costly than the insurance itself. But such a piece of prevention did not lend itself to headlines, and the kind of critic who went in for terminological fireworks could see no definite return for the money spent. The same was true of the expenditure on maternity and child welfare. The extra grants, entailing the expenditure of a few thousands, which had been made with a view to increasing the efficiency of nurses, health visitors, and others, by means of special training classes, had contributed to no small extent to the striking improvement in infant welfare statistics. A recent vote in Parliament, to cover a week's loss owing to the railway strike equalled the total expenditure by the Exchequer on the whole of the maternity and child welfare services in England and Wales for seven years. He was interested to see that one of the most flamboyant critics of his health expenditures had not hesitated to press for one more super dreadnought over and above the Admiralty requirements, and that Leviathan, if it were voted, would bury an amount equal to six or seven years' expenditure by the Exchequer on maternity and child welfare. Frankly, he himself would place the interests of British babies before the building of barracks in Baghdad. In conclusion Dr. Addison referred to his housing scheme, two features of which, he said, would gradually come to be realized: first, the condition that no local authority or private builder could build more than a certain number of houses to the acre; secondly, the condition, coming into force in 1923, whereby all the major authorities of the country would be required to provide a town planning scheme to govern the future development of their districts. This would lead to the gradual elimination of the biggest blot on our industrial system—namely, the inconsiderate crowding together of masses of the population, without regard to the needs of the people or the claims of the future.

Sir MALCOLM MORRIS, Vice-President of the Federation, was in charge of the toast of the Minister of Health. In proposing it he briefly reviewed the history of the Federation, which began, he said, in an effort to increase the number of medical men in Parliament. The medical men in the House of Commons numbered twelve at the present time. It was desirable that they should have fresh accessions. He hoped particularly that a woman doctor would find her way into Parliament to accompany the solitary lady who at present sat on the green benches. He hoped also that Lady Rhondda, whose interest in health questions was so acute, would secure admission to the House of Lords. The Federation had gone on to a wider effort to bring together the various organizations entitled to speak for the medical and allied professions. The central council of the Federation did not initiate schemes and then appeal to the constituent bodies. The Federation had no central policy, beyond that of providing a round table for conference. Its object was simply to secure the greatest common measure of effective opinion. It was faced with one great difficulty—the aloofness of the British Medical Association. As one of the officers of the Federation he would like again to offer to the British Medical Association the right hand of friendship. The Federation was not in antagonism to the Association; it did not want to interfere with the Association's autonomy, and it appreciated enormously the good work which the Association had done in the past. But on these health questions they ought to speak as one body, including all who were immediately concerned in national health.

Sir ALFRED MOND, in his response, agreed with the sentiment of the proposer that it was desirable that the medical profession should speak with unanimity and decision on questions of public health. When experts differed it was easy for the scoffer to refuse to listen to either party, and correspondingly hard for those who were responsible for administration. Proceeding, he said that he had himself fallen on evil days: not only did a layman succeed a medical man, but his predecessor began his work at a time when it was assumed that the purse of the nation was bottomless, whereas he took office when the nation was buttoning up its pocket. A Minister had to keep in his hands the clinical thermometer of the House of Commons and to watch the temperature chart of public

opinion. It was not for him to have recourse often to violent drugs which killed or cured, but rather to seek the aid of safer old-fashioned remedies which might produce some amelioration of the patient's condition. While it was difficult to advocate a launching out in many directions he deprecated any forfeiture of what had been gained of recent years. At the present time he was waiting for the report of Lord Cave's committee, and was doing all he could to expedite it. No one could contemplate without dismay the closing down of beds in hospitals. It was inconceivable that these great institutions should be allowed to curtail their operations; it could only be a question of ways and means of re-establishing them. He agreed with Dr. Addison that preventive medicine was not spectacular; indeed, if he wanted to achieve undying fame he would allow some great epidemic to break out, and then show with what energy his department could combat it. Medical research had to go hand in hand with preventive medicine. Without knowledge it was difficult to prevent, and even more difficult to cure. He hoped that some lessons would be learned from war strategy, and that disease would be attacked more and more in mass formation and not by solitary sniping. With the development of science he looked to the time when there would be no disease at all, in which case both the Ministry of Health and the medical profession would become extinct, unless, indeed, the community followed the example of the Chinese and remunerated doctors according to the number of days in the year that they were well. He paid a tribute to the value of medical men in the House of Commons, and added that he would always receive with gratitude any suggestions that the Federation might make to him.

Dr. FREMANTLE, M.P., in proposing the toast of the Federation, described himself as its parliamentary baby, for he owed much to its help in winning his by-election. Like Sir Malcolm Morris, he desired to hold out the hand of fellowship to the British Medical Association—an Association with so distinguished a record behind it. It was only as a loyal member of the Association that he proposed the toast. The organization of the Association was the most complete and logical scheme that could be based on a democratic principle. Any member of the profession who joined the Association found himself immediately related to its affairs, alike through its weekly JOURNAL, edited with such extraordinary ability, and through its local organization. But the Association had only managed to enrol two-thirds of the profession. He thought that a more fluid method of collecting and expressing opinion was called for, excellent as the Association's method was from the purely democratic point of view. Even among the Association's membership there were many who took no interest whatever in the procedure which was supposed to bring about their representation in the Representative Body and the Council. He did not despair of the democratic method, but some more adaptable arrangement seemed to be also required, and, moreover, the opinion of allied professional bodies should be elicited.

Dr. ARTHUR LATHAM, in responding to the toast, said that while certain individuals were resentful of new ideas, he did not believe that the British Medical Association in its constituencies was really hostile.

ANAPHYLAXIS AND IMMUNITY.

LECTURE AT THE ST. MARY'S HOSPITAL INSTITUTE.

THE lecture contributed by Dr. H. H. DALE, F.R.S., to the series on pathological research in its relation to medicine, which is being given at the Institute of Pathology and Research, St. Mary's Hospital, London, was on anaphylaxis and immunity.

He began by pointing out that anaphylaxis was not the opposite of immunity. It did not represent, as Richet at first thought it did, an increase of sensitiveness to a naturally poisonous substance. Anaphylaxis was a condition in which an animal responded by just the same type of reaction to normally harmless substances to which it had been rendered specifically sensitive as to poisonous ones. It might be defined as a condition of abnormal sensitiveness to a foreign protein, so that, whatever the nature of the action of the protein in question, whether ordinarily poisonous or not, the animal reacted to it as though it were an acute poison of a particular type. It was important to bear in mind that the characteristic of anaphylaxis was not the appearance of symptoms but the mode of their production. In the mode of its production and in its specificity anaphylaxis resembled immunity, though its effects seemed to be so strikingly different. The resemblance was strengthened when it was remembered that the condition of anaphy-

laxis, like that of immunity, could be transferred from one animal to another. Passive anaphylaxis, caused by the transfer of serum from the anaphylactic animal to the normal animal, did not operate immediately; an interval of from twelve to twenty-four hours after injection was necessary, even when the injection was intravenous, before the transfer of passive sensitiveness could be detected.

Practically all workers, with the conspicuous exception of M. Besredka of the Pasteur Institute, were unanimous in their opinion as to the nature of the anaphylactic antibody. It was generally recognized that the anaphylactic antibody was not a peculiar new kind of body, but one which had been long familiar to immunologists as precipitin. The evidence for this was not complete, but was complete enough to make any other assumption unnecessary. The limits of the specificity of the anaphylactic reaction were very closely similar to those of the precipitin reaction. The serum from the anaphylactic guinea-pig would convey the sensitiveness to a normal guinea-pig. The anaphylaxis so conveyed was not of a high degree, and a large quantity of serum from the anaphylactic animal was needed to transfer it. Much more efficient in transferring passive anaphylaxis was the serum from a rabbit which had had a series of injections of the antigen. The rabbit precipitin, injected into the guinea-pig, rendered the guinea-pig exquisitely sensitive to the antigen. If the anaphylactic antibody was not identical with precipitin, at any rate it was closely parallel in its formation. One fact, however, seemed almost fatal to this theory. The presence of precipitin could not be discovered in the serum of the anaphylactic guinea-pig; at least, the ordinary coarse precipitin reaction could not be obtained, though the presence of some reaction might be discovered with the ultra-microscope. On the other hand, if the guinea-pig, before it had time to become sensitive, were given not one but a series of injections of the antigen, an obvious precipitin in the guinea-pig serum was ultimately produced, but by this time the animal was not anaphylactic, and would tolerate large doses of antigen without harm.

Up to this point there was substantial agreement among immunologists; but two distinct theories now made their appearance. The first, which Dr. Dale said did not satisfy him, supposed that the reinjection of the antigen into the anaphylactic animal caused the production in the blood of a poison having a certain type of action, and to this hypothetical poison the name of "anaphylatoxin" had been given. Recently there had been a tendency to ascribe its formation to a physical rather than a chemical change. Some vaguely comprehended change in the state of colloidal equilibrium, something similar to the changes which preceded the clotting of the blood, was supposed to give rise to this anaphylatoxin. Dr. Dale, however, was not convinced of the direct connexion of anaphylatoxin formation with the phenomena of anaphylaxis. If a poison of this kind were really formed in the blood, an obvious way of producing the anaphylatoxin *in vitro* would be to mix the blood or serum of the anaphylactic animal with the antigen and inject into a normal animal. That did not work; there had been apparent successes, but in the vast majority of cases such injection was innocuous. More effective still should it be to inject into the blood simultaneously the antibody and the appropriate antigen; but that again did not work. The animal which was given the antibody and the antigen at the same time remained unhurt. Only when the antibody had been in the body for some hours did sensitiveness begin to appear, and not until it had been there for twenty-four hours or more did sensitiveness reach its maximum.

The other theory, and the one which the lecturer commended, offered an explanation for the fact that, after the antibody had been introduced into the normal animal, some hours had to elapse before sensitiveness began to appear. The antibody when circulating in the blood was not sensitizing but protective, and it had to get out of the blood before anaphylaxis could be produced. When once the anaphylaxis was fully developed, the injection of a further large dose of the antibody, instead of increasing the sensitiveness, immediately depressed it, so that the animal again became insensitive. He had repeated that experiment, and it worked. The obvious suggestion was that the antibody, when out of the blood, fixed itself in the body cells, and by its presence there and its reaction with the antigen, brought about something in the nature of precipitation in the sensitive cell protoplasm or

membrane, and that it was this which gave rise to the anaphylactic phenomena. On the other hand, excess of antibody, free in the body fluids, would bring about immunity because it caught the antigen and put it out of action before it reached the cells.

Anaphylaxis, therefore, was not the opposite of immunity, but a particular expression of the immune condition, due to the location of the antibody predominantly in the living cells instead of in the fluids bathing them. This explained why an interval was necessary after the injection of the pre-formed antibody before the animal became passively anaphylactic. It explained why the presence of sufficient antibody to circulate freely in the blood rendered the animal again relatively insensitive. Dr. Dale believed that this anaphylactic reaction represented a very fundamental type of resistance of the body cells to the incorporation into their protoplasm of a protein with a molecular pattern alien from their own. To resist this vitiation of its specific type the cell would die for the individual, or, if the body cells were subjected simultaneously to the attack, the individual would die for the parity of the species. The only chemical difference known between different species was a difference in proteins. The carbohydrates and fats were of a common type over a very wide range of species. It was in the molecular pattern of these complicated proteins, with its tangled skein of amino acids, that one had a chance of discovering the chemical difference which could be related to a specific or even an individual type.

Dr. Dale touched finally and slightly on the question as it affected practical therapeutics. There were some, he said, who would have them believe that the whole of the phenomena in patients suffering from an acute septicaemia could be explained in the terms of anaphylactic reaction. There was no warrant as yet for making such an assumption. Symptoms of the type seen in the anaphylactic reaction did not necessarily indicate anaphylaxis. There were, however, certain phenomena seen in man which suggested a close connexion with this condition. He instanced the rash and constitutional disturbance following the injection of horse serum, significantly after ten days' interval; also the various idiosyncrasies to foreign proteins seen in hay fever and "horse asthma," which had—to speak guardedly—many points of similarity to the anaphylactic condition.

THE INFLUENCE OF THE DUCTLESS GLANDS IN EVOLUTION.

PROFESSOR L. BOLK of Amsterdam, in a lecture to advanced students of the University of London, delivered on May 12th, dealt with the somatic changes in affections of the endocrine organs and their significance in the evolution of man. He raised many points of extreme interest, and made suggestions which were novel and often daring if not far-fetched, though Professor Gley's speculations (BRITISH MEDICAL JOURNAL, May 8th, 1920, p. 644) may have prepared our readers for them.

Dr. Bolk said that he had always been a strong supporter of the Darwinian hypothesis, and now maintained that the results of his researches were in no way inconsistent with, but rather afforded every confirmation of, the belief that Darwin had provided the correct solution of man's origin. Professor Bolk maintained that the various endocrine glands not only bore a definite and harmonious relation to each other and the organism as a whole, but that they had played a comparable part in the evolution and development of man from his primeval ancestry and origin. They exercised a sort of *imperium in imperio* of a suppressive or retarding character, without which the human race would never have attained its present state of civilization and dominance over the animal kingdom and realm of nature.

In support of the conclusions which he had formed from his research into the problems of endocrinology and evolution, he described certain features peculiar to man as representing the persistence of a primitive condition exhibited during foetal life by primates and higher apes. The hairlessness and absence of pigmentation of the skin in the white races were attributable to the retarding influence of hormones of the suprarenals on the distribution of hair and development of pigment which had taken place in the course of racial evolution. The specimen of a chimpanzee foetus at term, shown by the

lecturer, displayed characteristics so far human that pigment and hair were absent from the whole surface of the body save the scalp. It was in consequence of the withdrawal of the suppressive action of the suprarenal secretion after birth that the skin of the ape became hairy and pigmented.

The superiority of the fair-skinned, light-haired and blue eyed races over the pigmented and negro races might be traced *pari passu* with the extent of the retarding functions exercised by the endocrine glands on racial development. As evidence of the arrest of this function in the suprarenals in man was quoted the well-known pigmentation or bronzing of the skin occurring in Addison's disease.

To the retarding effect of the internal secretion of the thymus gland was attributed the delayed union of the cranial bones and open cranial sutures which had allowed of the growth and development of the human brain to its present eminence. On the other hand, by the removal of the inhibitory action of this particular hormone, there occurred premature closure of the sutures and irregularities in the normal rate of ossification, resulting in various rachitic manifestations.

Further examples of somatic evolutionary changes due to the activity of the endocrine glands and the retarding influence of their hormones were described. The pituitary gland was held responsible for the present conformation of the human skull and increase in capacity of the cranial cavity, the development of the chin, the retraction of the malar prominences, and the smallness of hands and feet which mark the higher races of mankind, in contrast to the small cranium, prognathos and high cheek bones of the apes and lowest human types as seen in the aborigines of the Australian bush. As an instance of disease in man resulting from the arrest of the retarding action of the internal secretion of the pituitary gland, mention was made of the hypertrophic overgrowth of bone and soft structures, so well known in acromegaly.

Attention was directed to the development of the labia majora as a human characteristic attributable to special hormones of the thyroid gland, and stated to be absent in apes and insignificant in female negroes.

In addition to the above-mentioned somatic changes, brought about in the course of evolution of man by the agency of the endocrine organs, these glands have also exercised an influence on the germ-plasm. As instance was given the retarding effect pertaining to the secretion of the pineal body, on the development of the male and female genital structures, which has resulted in an important delay of sexual function, particularly in the higher races of man, to a much later period than is found in the lower mammalia. The abeyance of this factor might, it was suggested, account for the comparatively early sexual development in the lower races of mankind—for example, the negro—and in part explain their racial inferiority.

Professor Bolk also attributed sexual precocity, a condition more often met with in females than males, to the absence of the retarding effect of the special hormone of the pineal body, and as an example quoted a case of pregnancy in a girl aged 7 years. Suggestions of considerable interest were offered as to the gradual influence of change of diet on man's evolution. The increasing amounts of animal food in place of a purely vegetable and fruitarian regimen were regarded as possible potent factors in the high cerebral functions attained by the human race.

The chairman, Professor G. ELLIOT SMITH, in proposing a cordial vote of thanks to the lecturer for his admirable address, commented on the great value of his studies. His own opinion, he said, was that the large size of the human brain could not be explained by assuming that it was due to the perpetuation of the proportion of the large brain to a relatively small body of an earlier stage of development, for it represented an active growth and elaboration, the fundamental factor in the evolution of man. Dr. T. R. Elliott had shown that this marked growth of the cerebrum was associated, in the human full-time foetus, with a striking modification in the structure of the suprarenal glands. He therefore tentatively suggested that this change might disturb the equilibrium of the endocrine glands, and prove the real mechanism whereby the great development of brain was itself responsible for restraining the full emergence of the simian traits of man's ancestor, rather than that this development should be due, as Professor Bolk had attributed, to the influence of change in man's diet.

MEDICINE A SCIENCE.

THE appearance of the second volume of *Studies in the History and Method of Science*,¹ edited by Dr. Charles Singer for the Oxford Press—a periodical or series of volumes which seems likely to become one of the chief mediums for the publication of essays in this department of knowledge—will move some readers to ask for a definition of science. In his preface to this volume Dr. Singer gives none, but in that to the first volume Sir William Osler, though he equally gave no definition, laid it down that the true and lawful goal of the sciences is the acquisition of new powers by new discoveries. It will be noted that Osler used the word in the plural. Sir E. Ray Lankester has recently quoted in more than one place Clifford's definition, if it may be so called, in which it was used in the singular: "The subject of science is the human universe; that is to say, everything that is, or has been, or may be, related to man." This is so wide as not to be very helpful, and, looking round for something more precise, Sir Ray Lankester suggests that the history of the word gives the explanation of its correct use at the present day. He points out that the French *Académie des Sciences*, founded in the middle of the seventeenth century, recognized various branches of knowledge; in doing so it did not go any further than Roger Bacon, of the thirteenth century, who recognized many sciences, by which term, however, he meant only a department of knowledge. It would seem that, as has happened in the history of many other words, the meaning attached to the term has been gradually and insensibly limited. The *New English Dictionary* recognizes that the word "science" in modern use is often treated as synonymous with natural and physical science, and thus restricted to those branches of study that relate to the phenomena of the material universe and their laws, sometimes with the implied exclusion of pure mathematics. It also recognizes that in a more general but still restricted sense it means a branch of study which is concerned with a connected body of demonstrated truths or with observed facts systematically classified and more or less colligated by being brought under general laws, and which includes trustworthy methods for the discovery of new truth within its own domain. Sir E. Ray Lankester's illustration rather confirms this view, for he says that the *Académie des Sciences* recognized various branches of knowledge as sciences, and that "very soon investigations made according to the rules laid down by those engaged in the building up of these 'sciences,' for the purpose of testing the soundness of conclusions and the systematic accurate application of those rules, were called 'scientific,' and the investigations so made and the resulting body of knowledge were called 'science.' The French Academy and the learned world generally definitely applied the word 'science' to all knowledge established 'scientifically,' that is, by the use of the scientific method." "In English speaking countries," he continued, "philosophers and the so-called 'men of science,'

have more and more definitely insisted on the importance of the 'scientific' method and the limitation of the word 'science' to knowledge tested and brought into order by that method."

All this is not logomachy, mere word-splitting; it is of great importance to medicine at this time, and has a very direct bearing on Sir James Mackenzie's address published elsewhere in this issue. It is a very long address, but the time given to its perusal will seem short, for it is well constructed and written and shows the direction in which the mind of one of the most striking personalities of the medicine of our time is working. Many people during the last generation have got out of the way of looking on medicine as itself a science; we have allowed it to be regarded as no more than a technical occupation, drawing information from various sciences, but not in its own methods and material worthy to be reckoned a science. So widely has this opinion come to be entertained that it is even adopted and applied by the Inland Revenue! Sir James Mackenzie does not mention the doctrine in so many words, but all through his address he is in effect challenging it. He is directly concerned with rebuking us for not giving sufficient attention to prognosis; but to make his point about this he has to show that medicine does in fact use the scientific method, and that its study, in common with that of other sciences, is conducted by way of investigations made according to certain rules recognized by all men of science as appropriate for testing the soundness of conclusions. It fulfils also the further requirement demanded of a department of knowledge claiming the status of a science, in that it is concerned with a connected body of demonstrated truths and observed facts colligated—though, it is true, to a very inadequate extent—under general laws and possessing trustworthy methods for the discovery of new truths within its own domain.

Medicine is concerned both with truths that can be demonstrated by experiment and with facts that can be established by observation; the relation of its two parts is very much that of physics to astronomy; but while the fame of astronomy has been continually increasing in the ears of all men, the observational part of medicine has rather lost credit. Sir James Mackenzie in his zeal for it may seem here and there a little in danger of depreciating the experimental side, but there is small chance of any harm befalling.

It is, we believe, true that he is to some extent preaching to the converted, and that the physiologists, the pharmacologists, the pathologists, perhaps even the bacteriologists, are becoming alive to the true situation; they have begun more clearly to perceive that not only does medicine want their facts, but that they must understand the nature of the problems and difficulties of medicine, and must, in order to enjoy to the full the stimulus it can give to their own work, study its methods "for the discovery of new truths within its own domain." Sir James Mackenzie lays stress on medicine's methods other than the experimental, and in particular on those which must be used for the study of prognosis. The power to foretell is the most difficult and usually one of the latest to be achieved by any science founded on observation. The address is very severe in its criticism of modern medicine for its neglect of the study of prognosis; there is truth in what he says of the skill of practitioners of an older generation in this respect. He would attribute it, we gather, in part to the fact that, having to depend more on their own unaided observations, their senses became more highly trained and they got to know their patients better. The account

¹ *Studies in the History and Method of Science*. Vol. II. Edited by C. Singer. Oxford: The Clarendon Press, 1921. (Imp. 8vo, pp. 581; 78 figures, 55 plates, 48s. net.)

he gives of his own errors, labours, disappointments, and successes is at once fascinating, instructive, and encouraging. The whole address is a moving appeal to the general practitioner of medicine to take his share, which is the most important share, in advancing this most difficult department of medicine. It is an appeal by one who knows of what he speaks, one who has himself trodden the anxious path he bids others follow.

THE SURGICAL TREATMENT OF ANGINA PECTORIS.

JONNESCO's operation for the relief of angina pectoris by excision of the sympathetic ganglia and interruption of centripetal paths from the aortic and cardiac plexuses, successful though it was in many respects, was not entirely satisfactory either from the physician's or the surgeon's point of view. No isolated piece of evidence could be. There is now another case to throw into the scales. In 1914 Rénon¹ had a female patient, 62 years of age, who was known to have had an aneurysm of the aorta since 1910; she was a woman of great energy, and she had suffered so severely from dyspnoea, thoracic and cervical pain, and headache that she declared herself desirous of operation, let the risks be what they might. The aneurysm, as revealed by x rays, was discrete, fusiform, situated in the ascending aorta, and surrounded by "considerable mediastinitis." Syphilis had been present but had been treated, and the Wassermann reaction was negative in 1914. Tuffier² attacked the case *quid* aneurysm—that is to say, he exposed the aorta by a transverse division of the sternum opposite the second intercostal space; found a fusiform aneurysm 2 in. long, beginning a finger-breadth above the origin of the vessel and of a circumference twice that of the normal aorta; he "isolated" it, and speaks of this as an easy matter, though one of the onlookers, Rénon, says it was the longest part of the operation. He then wound round and round the whole length of the aneurysm a long strip of fascia lata, applying two superposed turns just below the bulge, in such a way as slightly to constrict the normal arterial lumen.

The result of the operation seemed rather more satisfactory to the surgeon who operated, and who speaks of her as "free from functional troubles for four years after," than to the physician who subsequently treated her for "a sensation of intrathoracic cramp," for "pains in the back and neck," for "slight bronchitis," and who mentions that suppuration occurred in the wound round a silver suture in the sternum, accompanied by "violent pains in the thorax." In 1919 the Wassermann reaction was found to be positive once more, and further treatment was given. The woman died in 1920 of recurrence of carcinoma of the uterus, for which she had undergone hysterectomy earlier in that year. No necropsy was permitted.

Rénon's conclusions amount to this: The feasibility of the operation has been established, for the patient's death six and a half years afterwards was not to be ascribed to the aneurysm; there was some amelioration of symptoms; the general state was better, and the pains, though severe at times, were much less frequent than before. He thinks the improvement due to "liberation of the mediastinitis by dissection of the aneurysm," which, however, was not permanently reduced in calibre by the intervention.

It may be remarked that in view of the known relation between the development of an aneurysm and progressive deterioration of the muscular and elastic elements in the wall, and the lack of resistance displayed by all other tissues, encirclement by a band of fascia promised no more than postponement of the evil day, and seems to have accomplished little.

However, when Rénon's paper was read at the Académie de Médecine, Delorme imported great interest into the discussion by pointing out that whilst dissecting or freeing the aneurysm, in the admitted presence of mediastinitis, Tuffier must incidentally have divided or removed the sympathetic plexuses on the anterior and left aspects of the aorta, and that this made it necessary to seek another explanation of the relief of the angina. He referred to Jonnesco's interruption of the reflex arc by dividing the centripetal fibres from the plexuses to the bulb, and reminded his audience also of the work of Leriche,³ who treated many war cases of ischaemic, or mixed ischaemic and neurotrophic "blighted" limbs by excising the sheath of the main artery. The surmise on which the operation is based is that by interrupting the sympathetic plexus about the vessel the surgeon secures dilatation of the vessels beyond, and recovery from palsy and trophic conditions, including matting of the tissues, supposed to be due to nerve injury.

This work of Leriche, Jaboulay, and Heitz, though it has found support from other surgeons,⁴ needs further confirmation, for it has even been denied that vascular nerves pass distally as a periarterial plexus at all, and direct supply of the arteries from nerve trunks has been demonstrated. Still, it is established that severe organic changes in the vessels may result from lesions of nerve trunks, and it is agreed that, in whatever way the fibres reach the walls of the aorta stimulation of their terminals therein is the starting point of anginal pain. Delorme pointed out that such a regional sympathectomy can have only a limited application, and that, so far as the progress of an aneurysm itself is concerned, it might even be a menace. On the other hand, as a variant of Jonnesco's method it may find a value in the relief of symptoms. Delorme also made reference to his work on "cardiolysis"—more accurately known as "pericardiolysis"—which has a somewhat similar basis to the precordial thoracostomy referred to recently by Dr. Blackhall-Morrison⁵ in our pages.

Rénon's case lends some support to the view that symptoms of cardio-vascular origin may be made amenable to surgery, and the report is welcome in that it affords still further witness to the turning of attention from the coagulation of contained blood to the condition of the containing walls in the treatment of aneurysm; it indicates a short step forwards towards the period foretold by Lauder Brunton, and indicated in greater detail by Vaquez,⁶ when "irremediable" conditions associated with heart and vascular disease shall successfully be brought within the realm of surgery. Not the least of the benefits accruing from war experience is a greatly increased familiarity of a large number of surgeons with intra-thoracic intervention on the widest scale, which justifies operations, hitherto perhaps foolhardy, in the presence of urgent and unsupportable symptoms.

The medical profession may well congratulate both Rénon and Tuffier on their courage and their success.

AN ANNUAL STOCK-TAKING.

ANYONE who finds himself in doubt as to the exact nature of the claim of the British Medical Association on the interest and support of the individual practitioner, to whatever section of the profession he may belong, will find his difficulties speedily resolved if he can attend the annual meeting at Newcastle. For the meeting considered as a whole affords at once an exposition of the aims of the Association in their totality and a practical commentary upon the way in which the several portions of the machinery of the Association work.

As will be seen from the programme of the Sections of the Annual Meeting, published in the SUPPLEMENT, the subjects selected for discussion at Newcastle include not a few of those by which the mind of the profession is at present most exercised. The retiring President, Sir Clifford Allbutt, will introduce in the Section of Medicine the discussion on visceral syphilis, especially of the central nervous and the cardio-vascular systems; and it will be observed that the special Section of Venereal Diseases intends to concern itself rather with therapeutics than polemics. The Section of Surgery will hold discussions on acute pleural empyema, on compound fracture of the thigh and leg, and on the diagnosis and treatment of injuries of the intestines, and will have the opportunity of witnessing demonstrations by its president, Professor Rutherford Morison, and others. The Section of Orthopaedics and Diseases in Children will also hold three discussions—one on the early diagnosis and treatment of anterior poliomyelitis, the second on blood diseases in children, and the third on tuberculosis of bone. The Section of Obstetrics and Gynaecology will discuss Caesarean section, and the neurasthenic element in midwifery and gynaecology, the latter subject being introduced jointly by an obstetrician and a neurologist. In the Section of Radiology and Electro-therapeutics (in the presidential chair of which Dr. Knox at short notice takes the place rendered vacant by the lamented death of Dr. Ironside Bruce) there will be a discussion on the changes induced in blood constituents by radiations—a subject which will be examined both from the experimental and clinical points of view.

Abstract consideration of the programme of the meeting, though a poor substitute for the practical experience of those who can take part in it, will be sufficient to show that the work of the Sections, the deliberations of the various conferences, the addresses and social features of the gathering, fall into place as component parts of a conception which touches at some point the interest of every member of the profession. Three aspects of the Annual Report of Council, which forms the chief basis of the discussions at the Representative Meeting, may be distinguished. All of them are essential to full appreciation of its significance. As will be seen from its perusal (it was published in the SUPPLEMENT of April 30th), it is, in the first place, a record of work accomplished, a summary of the practical achievements of the Association during twelve months. In the second place, it is a review of the collective experience of the profession throughout the Empire, an account of the environment which must inevitably play a determining part in the development of the practice of medicine. Finally, it contains, in the recommendations to be laid before the Representative Body, the outlines of a policy for the immediate future.

In its first aspect the contents of the report need little emphasis. They are such as the series of reports

which has preceded it have rendered familiar, and they will surprise only those who have accepted without investigation the old criticism that the British Medical Association is impotent or lethargic in fields other than those of science. As against such criticism it is shown how widespread is the Association's work in Australia, New Zealand, and South Africa, and how it is extending the sphere of its activity in the newly defined territories of Africa, in the Far East, and in the islands of the West Indies—successful in turn in the service of the individual member and of the sectional interest, in central action and in local. In definite increase of remuneration and improvement of conditions of practice, groups as diverse as the practitioners called to give evidence at courts-martial, the women practitioners in the service of the Metropolitan Asylums Board, and the practitioners in the Notts colliery area have alike profited, to quote at random from the full list, which, beyond equivocation or dispute, covers every field open to the qualified medical practitioner as such. The revision of the Draft Regulations under the Dangerous Drugs Act, 1920, balances these examples with an instance of action directly affecting almost every section in a greater or less degree. Such a record, besides its intrinsic interest, is a fitting background to the claim of the Association to represent the whole profession in a sense true of no other body. It should be kept in mind in any discussion of the negotiations with the Ministry of Health in respect of the constitution of a central committee representative of the whole profession, and suggests a new application of the old practical maxim, "What touches all should be approved of all," which underlies such negotiations.

As already pointed out, the significance of the report is by no means exhausted by a consideration of the successes achieved. It is essentially an epitome of professional experience during the period under review, and as such it records much work, the fruition of which is for the future. Such is the progress recorded in connexion with the model scheme for attendance on dependants of miners and other workmen, or the successful initiation of legislation for the security of tenure of public health officers. It includes also some instances of failure to attain objectives which seemed at one time well within reach. Such instances are instructive, for they illustrate two facts sometimes forgotten alike by critic and by partisan: first (as in the case of the postal medical officers) that the British Medical Association cannot act successfully for those members who cannot help themselves to the extent of expressing their views on matters touching their own interests; and second, that a period of peculiar difficulty will have to be met in the immediate future. More than once, as in the matter of superannuation for public health officers, the Council is obliged to report that the time is not opportune for further progress. This is simply to say that the medical profession cannot hope to escape the effects of prevailing economic conditions. Salaries and fees are not immune from the influences which have already brought about substantial reductions in the general level of wages, and threaten to retard if not to arrest the national works of reconstruction so hopefully undertaken after the armistice.

Amongst the other matters which call for particular attention, primarily from the section of the profession directly affected, but ultimately from all who are concerned in the general developments of the future, are the relations of certain sections with the Whitley Councils recently formed for the central (or national) and local government services; the position with

regard to the transfer of insurance practices; the ultimate form of the insurance record cards; and the lesson to be drawn from the Tasmanian Medical Act. Old foes with new faces are to be discerned here and elsewhere in the report.

So far, the report has been treated primarily as a record, and a few specific points selected for comment as an index to its general scope and character. For practical purposes, however, interest naturally centres upon the interpretation to be placed upon the experience recorded and the decisions which will determine the special direction of the Association's policy for the coming year. Apart from the recommendations touching the machinery of the Association, and the question of federation, which have been fully dealt with in recent leading articles, and the postponed discussion on the Reports of the Consultative Councils of the Ministry of Health, the main matters for debate (adopting the order in which they appear in the Report) are those presented under the headings of Medical Ethics, Medico-Political, and Hospitals.

Under the first heading comes a proposed definition of the attitude of the Association towards questions involving the principle of professional secrecy. The suggested solution lies in a sharp distinction between those cases in which the law as at present existing provides in the public interest for the communication of information obtained in the course of professional duties, and the case in which administrative action may tend to the enforcement of further exceptions to the rule of professional secrecy. It is recommended that the whole weight of the Association should be lent to initiate and support resistance to such encroachments. The second item of note is the proposed scheme for grading and remuneration of medical professors and teachers. A matter of sectional application in a limited sense, since the number of persons affected is numerically small, its importance to the teaching of medicine cannot be over-estimated. A decision is the more urgent because a general settlement of the problems of University teachers, so long overdue, might seriously prejudice the interests of the teachers of medicine, failing some authoritative exposition of their case for special consideration. Last come the two series of recommendations covering respectively the question of the future of the voluntary hospitals, and the utilization of the Poor Law infirmaries. Events of the last few months have brought problems of this order into prominence, and the urgency of forestalling either a national settlement or local experiments which may harden into local custom and finally secure establishment through national legislation, has apt illustration in the Bradford episode.

The whole hospital question, complicated as it is by the workings of what may perhaps be characterized as the "vested sentiment" of the community, demands the exercise of the highest qualities of statesmanship. The medical profession has to convince the public that its contribution to the settlement so impatiently demanded is determined in the long run by a correct interpretation of the public need, rather than by motives of professional self-interest. Only so can it hope to ensure that the adoption of some short cut to an immediate solution will not indefinitely postpone constructive measures of reform. A great step forward is marked by the measure of agreement amongst the honorary staffs of voluntary hospitals obtained through the medium of the Association and embodied in the recommendations contained in the first series. It is not sufficient, however, to deal with the readjustment of the old system. The recommendations on the voluntary

hospitals have to be supplemented by recommendations on the future utilization of the Poor Law infirmaries. Agreement upon the guiding principles to be accepted on this subject will be no unimportant contribution, alike to the needs of the profession and to the orderly development of the health services of the country.

INTERNATIONAL HEALTH WORK.

It has long been recognized that measures directed to the prevention of disease cannot achieve their full purpose unless they are international in character. This view was held by those engaged in the peace negotiations in Paris in the early months of 1919, and as a result Article XXIII of the Covenant of the League of Nations binds the members of the League to "endeavour to take steps in matters of international concern for the prevention and control of disease." The practical outcome of this conclusion is the establishment of a permanent International Health Section of the League of Nations and the formation of an Industrial Hygiene Department of the Labour Section of the League. This department is concerned with the "protection of the worker against sickness, disease, and injury arising out of his employment." With a view to assisting the International Labour Office in the solution of problems connected with industrial hygiene an advisory committee is now being formed which will include Government medical inspectors of factories and experts attached to organizations of employers and workers or to industrial establishments. International agreements have already been secured through the instrumentality of the Labour Office with regard to measures for the prevention of anthrax and in connexion with lead poisoning, and these two questions will be discussed at the October meeting of the International Labour Office. In this country provision was made in the Factory and Workshop Act, 1901, with respect to cases of anthrax or lead poisoning contracted in a factory or workshop. Notification of both diseases occurring under the circumstances named must be made by the medical practitioner in attendance to the chief inspector of factories at the Home Office, and the employer is required to give notice of the cases to the certifying surgeon and the local factory inspector. In those factories in which lead processes are carried on and where women or young persons are employed, suitable washing conveniences must be provided, meals must not be taken in rooms where lead is used, and mechanical means must be installed for carrying off the dust. Periodical examination by the certifying factory surgeon of workers in lead is included in the preventive measures in force. Regulations have been made with respect to factories and workshops in which infected hides or wool are handled. These include the provision of washing conveniences with a supply of soap, towels and nail-brushes, the compulsory washing of the hands before partaking of food, the non-employment of a worker who has an open sore or cut, and the provision of suitable fans for the extraction of dust. In carrying out its task of protecting the worker against disease arising out of his employment the International Labour Organization will receive material assistance from the pioneer work of the Home Office, initiated and carried out by Sir Arthur Whitelegge when he held the position of H.M. Chief Inspector of Factories; of his labours it is impossible to speak too highly.

THE EPIDEMIC OF UNREST.

At a meeting of the Society of Arts on May 25th Dr. C. M. Wilson read a paper on "Some effects of the war on industrial unrest." His remarks were for the most part a careful analysis of the present mood and temper of labour. To begin with, he distinguished the case of the

man who had seen active service from that of the man who had remained at home. The latter, if he had done so involuntarily, and had been a target of abuse, was filled with a sharp sense of injustice, and if he had avoided active service without any valid reason he was suffering from a loss of self-respect proportional to the good that was in him. In either event his mental state was morbid, making him much more difficult to deal with than the ex-soldier. In such a soil grievances flourished, and such a man became unduly eager to exhibit his valour in different directions. From this Dr. Wilson passed on to describe some of the causes that led to unrest in the trenches, such as the "cooking" of war news for home consumption and the decline in authority consequent upon the perception that the mental outfit for leadership was generally lacking. Men in the mass were now more critical than before the war, and were less inclined to believe what they heard and read. They had been prepared by the war for an appeal based on something higher than self-interest, and the opportunity had not been taken by employers. He regretted that the captains of industry had not generally followed the example of the officers of the old regular army in devoting themselves unselfishly to the needs of the men, and giving them that personal leadership which had proved its value in the field. The discussion on Dr. Wilson's paper was somewhat diffuse, but it was made interesting by Dr. Graham Little's testimony to the working man—all members of the medical profession, he said, who were privileged to come into contact with the working man had a very high opinion of him—and by Dr. Charles Buttar's footnote to Dr. Wilson's theme. Dr. Buttar contested the implication in the title of the paper; unrest was not confined to the industrial population, and he doubted whether it was caused by the war, for possibly the war itself was only a symptom of a larger unrest. To his mind the epidemic of unrest was due to the want of a satisfying object in life, to love of money, and the false pursuit of happiness. He saw no hope of happiness in many of the weird cults and beliefs which were taking the place of the ancient faiths; nor was true happiness necessarily to be found in rolling along high roads in luxurious cars; nor, again, was the smashing of the machinery of civilization in a crusade of labour against capital likely to bring about the millennium. He believed that salvation would only be found in a return to ideals similar to the old ideals—a faith for some, work for most, and a sense of duty for all. This sentiment drew the warmest applause of the evening.

TELL-TALE TREATMENT.

AMONG the kings of France one of the best known to readers of English literature is Louis XI. This is due to the genius of Scott, who, in his portrait of the King, drew a picture of mingled astuteness, cunning, cruelty, and superstition not easily to be forgotten. Attempts have been made to whitewash him, and no doubt by his successful efforts to curtail the power and independence of the greater feudal nobles he had a share in the unification of France. But Scott's view of his character is that generally accepted, and reflects the opinion of Louis's own time and of the majority of French historians. In a volume reviewed elsewhere in this issue Dr. Cabanès has come forward with a suggestion which may explain, if it does not excuse, some of the darkest traits in Louis's character. The suggestion was made in the course of some lectures on the light clinical medicine may throw on general history, and was given as an illustration of the doctrine *naturam morborum ostendunt curationes*—the method of treatment indicates the nature of the disease. Louis XI on one occasion wrote a letter to the Prior of Notre Dame de Salles at Bourges as follows: "Master Peter, my friend, I beseech you as earnestly as I can at once to pray to God and Our Lady of Salles for me that they may be pleased to send me a quartan fever, for I have

a disease of which the physicians say that I cannot be cured without having it; and when I shall have it I will straightway let you know." Voltaire had read the letter and was very scornful about it, but he did not read it with sufficient care. He says that the King asked to be granted quartan fever, which would be good for his health, and exclaims, "The impudent quackery of the doctors was as great as the stupidity of Louis XI and his stupidity equal to his tyranny." But Louis did not say that a quartan fever would be good for his health; he said that he had a disease which could not be cured unless he had a quartan fever; the only conclusion the statement justifies is that Louis had a disease worse than a quartan fever, and this Voltaire might have perceived had not his anxiety to find a stick with which to beat the doctors blunted his customary acumen. Dr. Cabanès recalls the observation attributed to Hippocrates and well known to mediaeval medical writers who founded themselves on him. It was thus stated by one of them, "if an epileptic is once seized with quartan fever he is better for the most part of his time." Dr. Cabanès's suggestion is that Louis suffered from epilepsy; if he did it would account for a good many things about him, his fits of moroseness, for instance, and his periods of seclusion. Dr. Cabanès can explain why the King addressed his request to the Prior of Notre Dame de Salles; it was because that sanctuary was much frequented by pilgrims from the ague-stricken district of Sologne where there is still much marsh land. In no other sanctuary, Louis might argue, would the way in which fevers were contracted be better understood or the supply larger. On another occasion Louis made inquiries about Notre Dame d'Embrun, a sanctuary with a reputation for the cure of epilepsy. Dr. Cabanès finds confirmation of his suggestion in other facts known about remedies taken by Louis, since among them were many deemed useful against the falling sickness; in this way the dark stories of how the King took baths of human blood may be accounted for, since to drink human blood was sovrain against epilepsy. Possibly the King had also some other disease; a contemporary affirmed that he had leprosy or something like it. In 1483 Louis sent an expedition at considerable cost to the Cape Verde Islands, the purpose of which has puzzled historians. One of these islands was it is said, visited by lepers in the hope of cure; the treatment consisted in rubbing the skin with the blood of tortoises, which were plentiful there, and eating the flesh and fat. Perhaps Louis had some chronic skin disease, or possibly he thought that tortoise blood might be better for epilepsy than human blood. Whatever we may think of this, Dr. Cabanès's first conjecture about quartan fever is a good illustration of his thesis.

A MEDICAL PRIME MINISTER.

M. EMILE COMBES, once Prime Minister of France, died on May 25th, at the age of 86, at Pons, a small town on the road between Cognac and Bordeaux, where at one time he had practised medicine. He was a southerner and was born of poor parents in the department of the Tarn. He was educated at Roman Catholic seminaries, and as a young man taught in Roman Catholic colleges at Nîmes and Pons. At the age of 25 he wrote a book on the psychology of St. Thomas Aquinas, but his opinions underwent a revolution, and two years later, at the age of 27, he determined to begin the study of medicine in Paris; he took the degree of M.D. in 1868 and settled in practice in Pons. The first public office to which he was elected was that of Mayor of Pons; in 1879 he was elected a member of the Conseil Général of the Department of Charente Inférieure, a body possessing powers in some directions greater and in others smaller than a county council in England, but exercising more political influence. Combes was defeated when he attempted to enter the Chamber of Deputies in 1881, and it was one of the peculiarities of his career that he never

belonged to that body. He was elected to the Senate in 1835, became its vice president in 1894, and remained a member of it until the end of his life. His first portfolio was that of Education and Public Worship in 1895, and though the ministry only remained in office for six months Combes gave sufficient indication of his anticlerical disposition to alarm the moderate parties. His views, however, were popular, and his influence grew steadily during the ministry of Waldeck-Rousseau (1899-1902); in June, 1902, he became Prime Minister. Under Waldeck-Rousseau a law had been passed requiring the religious orders to obtain from the State authorization to continue their work. Combes, with the support of the parliamentary party which went by the name of the Bloc, broke off relations with the Vatican and withdrew from the religious orders the right to teach in France; he was no doubt, for all practical purposes, justified in saying that the concordat established by Napoleon was then brought to an end, though it was left to his successor to complete the separation of the churches from the State. While engaged in this bitter controversy at home, in his conduct of foreign affairs M. Combes sought to make friends for France by pursuing a policy of conciliation, and his hope was to find in arbitration a safeguard against war. He entered into arbitration agreements with Great Britain, Italy, Holland, Norway, Sweden, and Spain. After the resignation of his ministry in 1905 he seemed to retire, but continued to play a considerable part behind the scenes and made and unmade more than one ministry. During the war he subordinated any personal ambitions he may have retained to the common good, and was a member of M. Briand's Cabinet (1915-16). Thus, of the Prime Ministers of France in this century, two of the most conspicuous, Combes and Clemenceau, were members of the medical profession. The qualities which brought the latter to power are easy to comprehend, but it is not so easy for a foreigner to understand the sources of the influence Combes exercised on the course of French politics. It was unquestionably great, and for nearly twenty years he was probably the most prominent of French politicians. His success is the more surprising since when he entered on a political career he was much older than most men who attain success in it; he was then 50 and had spent some twenty years in the arduous work of a doctor in a country district. His influence, it would seem, was in large measure due to a certain honesty and simplicity of character which he retained to the end.

IMMUNITY AND INDUSTRIAL DISEASE.

BEFORE the Royal Society of Arts, on May 30th, Sir Kenneth Goadby read a paper on immunity and industrial disease. Very little, he said, was known of individual susceptibility and immunity to many of the corrosive substances used in manufacture; thus, in the dyeing of yarn with chrome, certain workers suffered from ulceration after a very short time, while others had a slight but recurrent dermatitis which only after long exposure degenerated into deep and penetrating ulcers. In this instance natural immunity and susceptibility played leading parts in the appearance of the disease. Individual susceptibility explained many curious forms of ulceration seen in such trades as confectioners, drug manufacturers, felt hat makers, and the fur trade. Diseases arising from dust, fumes, and vapour comprised a large section of industrial disease, and amongst the air-borne diseases lead contributed by far the largest number of cases. The high incidence of lead poisoning in the painting trades was difficult to understand, as lead-dust inhalation was the chief source of lead poisoning, and except in dry rubbing down the painter is not exposed to lead dust. An acute attack of abdominal pain often followed breathing the air of newly painted rooms; it was due, the lecturer believed, to turpentine poisoning. Arterio-sclerosis, resulting in increased blood pressure, was admitted to be a common disease among

painters; a comparison of the blood pressure of painters working with leadless paint for some years with the blood pressure of workers engaged in the manufacture of white lead showed that the latter as a whole had a much lower blood pressure, according to their age group or according to the period for which they had worked, than painters. The painter's occupation, therefore, apparently entailed some risk contributing to high blood pressure not present amongst the white lead workers; this might be associated with the vehicle used for the paint, the chief constituent of which was turpentine and its substitutes. While ailments common to the whole population might be augmented by industrial disease, it was equally true that minor affections predisposed to industrial diseases, especially the large category of small but persistent microbial poisons emanating from septic mouths, unhealthy tonsils, persistent catarrh, and long-continued constipation, all and each of which sooner or later diminished the power of the blood to resist other poisons. The fact that individual susceptibility and immunity were factors in determining much of the special disease in dangerous trades suggested certain general blood tests, whereby susceptible persons could be eliminated from an occupation inimical to their well being. The blood tests were simple, and the estimation of blood pressure an ordinary routine of medical practice. A selection of workers for especially dangerous processes, following the general indications outlined—for instance, alterations in blood pressure and the white cells of the blood after a short exposure to the dangerous trade influences—would, the lecturer urged, not only reduce the incidence of industrial poisoning in many occupations, but might even render safe some trades now regarded as dangerous. The great proportion of the work in dangerous trades was non-skilled, so that no hardship would arise from an elimination of susceptibles. Even the painter served an apprenticeship, and during the earlier time was a labourer; two special examinations, one at three and one after six months' employment, would be sufficient to eliminate susceptibles. The general principle of selection for a given occupation was carried out to some extent in many walks of life, and it did not seem unreasonable to extend the method. A trade union organization charged with the general improvement of the health of its members would have the whole-hearted co-operation of the public at large and command universal attention.

PEARL PATHOLOGY.

As there is a very general but erroneous impression that a pearl is formed around a parasite, as the process is, in fact, pathological, and as the production of the Japanese artificially induced "Mikimoto" pearl is a curious example of minute plastic surgery, the following notes, founded on a paper published last week in *Nature*, by Dr. H. Lyster Jameson, who announced Mikimoto's first successes to the Dandee meeting of the British Association in 1912, possess some medical interest. It is first to be noted that certain small pearls which have no commercial value are produced in *Mytilus* by the specific stimulus of a trematode. How pearls such as those produced by the Ceylon pearl oyster originate has not been ascertained. Only in a few instances are foreign bodies, such as radiolarian shells, sponge spicules or quartz grains, found at the centre of the pearl. Usually the nucleus is composed of a kind of shell substance of pathological origin, identical with that with which the oyster repairs an injury to its shell. The free surface of the mantle of an oyster is formed of cylindrical ciliated epithelial cells; the shell is produced by the outer shell-secreting epidermis, consisting of cubical cells. If a foreign body, such as a piece of mother-of-pearl, is inserted between the shell-secreting epidermis and the shell, shell substance is laid down, forming what is called a blister, more or less hemispherical, projecting from the shell and continuous with

its inner surface. By this method the Chinese induce fresh-water mussels to coat tiny images of Buddha with mother-of-pearl, and a similar experiment was carried out by Linnaeus in the eighteenth century. The coated images are merely curiosities and the commercial value of the blistered pearls is low. Mikimoto has got far beyond this; the natural pearl is formed in an epithelial sac, which has somehow been formed in the parenchyma of the mantle or muscle. It is this epithelial sac that Mikimoto imitates, a process demanding the most delicate and skilful manipulation. The shell of a pearl oyster is removed and a bead of nacre or other suitable nucleus is laid down on the outer, shell-secreting, epidermis of the mantle. The epidermis is then dissected off, and wrapped round the nucleus to form a sac; the neck of the sac is then ligatured. This sac is next transplanted into a second oyster and embedded in the parenchyma of its mantle. The ligature is then removed, astringents applied to the wound, and this second oyster with its grafted pearl sac containing the mother-of-pearl bead, is returned to the sea, where it remains for several years—seven or more—until a coating of pearl substance of sufficient thickness is secreted around the introduced bead. A pearl can be formed only in a pearl sac, which, as has been explained, is a closed cavity lined by nacre-secreting epithelium. Apparently a pearl sac must owe its origin to a traumatism of some kind, unless we suppose that it may be a congenital deformity.

VITAMIN.

RECENTLY in a note upon the spelling of chemical terms (April 9th, p. 539), it was stated that the rule of the Chemical Society must be interpreted to require the spelling of vitamin without the terminal "e." A correspondent now inquires as to the pronunciation. We had supposed that there could be no doubt that the first syllable was long and the "i" in it produced in the English manner (according to the analogy of "vital"). On the question of length we have consulted Sir Clifford Allbutt, who has no doubt that the first syllable is long—vita. "I have," he says, "looked in such lexicons as are at hand, to see if at any time the length was in varied use, but find no authority for any short use. No doubt in coining the word vitamin vita was used in no antiquarian, but the ordinary sense: 'tenues sine corpore vitae' (*Aenid*, vi, 292)." We have heard the word pronounced with the "i" as "ee" in Continental fashion, but we believe this to be unusual. The word was coined by Casimir Funk, who thought these bodies contained amines and even gave a formula for them. As he regarded them as necessary to life he called them "vitamines." They are, however, not amines. The term used by Professor Gowland Hopkins, "accessory food factors," which is descriptive and non-committal, would be the best hitherto suggested were it not so long. Professor Armstrong proposed the word "advitant," indicating simply that the substance is necessary to life; but it is an awkward and ugly word. Dr. John Brown suggested "vitoids" (an awkward word) and also "biogen," which, by suggesting the analogy of fibrinogen and so on, seems to us bad. Probably "vitamin" is too well established to be displaced, and we notice that Colonel McCarrison, in his book just published, to which he gives the title, *Studies in Deficiency Disease*, speaks throughout of "vitamins."

SURPLUS MEDICAL STORES.

THE Surplus Government Property Disposal Board has lately arranged with the Joint Council of the Order of St. John and the British Red Cross Society to offer surplus army medical stores and hospital equipment for sale on special terms to hospitals and kindred institutions. It is hoped by this means to aid the voluntary hospitals in meeting the urgent economic problems that now face them, and at the same time to benefit the

taxpayer. The stores have been brought from the various collecting posts throughout the country into one large dépôt at Shepherd's Bush, where they have been examined and graded into two categories—the new and the used or partly worn—the latter having been overhauled, adjusted, and renovated. The total value of the stores now collected in a vast hangar near Wood Lane Station, is about one million pounds. They include a large amount of dental and x-ray appliances, half a million surgical instruments, a great deal of operating-room furniture, and about fifty tons of drugs. The arrangements have been carried out under the direction of Sir Howard Frank, the new chairman of the Disposals Board, and Sir Napier Burnett, M.D., chief executive officer to the Joint Council. A catalogue has been printed and every item in the sale list is now being priced at a level which it is hoped will offer a strong inducement to the hospitals and nursing institutions of the country to replenish and renew their equipment. The dépôt will be open for the inspection of the goods on June 14th, and will remain open each day, except Saturdays, until further notice. Invitations have been sent to hospital authorities to visit the dépôt, and no one will be admitted to it without an official permit from the Hospital Service Department, 19, Berkeley Square, W.1. Permits will be issued to 100 hospitals each day, but no sales will be effected until all the hospitals have had an equal opportunity of viewing the goods and making their choice.

LANGLEY PRIZE IN TROPICAL MEDICINE.

A PRIZE has been instituted at the London School of Tropical Medicine in memory of the late Dr. W. A. Langley, C.M.G., Principal Medical Officer of Southern Nigeria, who died in 1912. The fund was raised principally on the coast. The war intervened and all the papers and subscription lists went down in the sea. When Dr. Lynch Burgess, of the West African Medical Service, who was treasurer of the fund, lost his life. Dr. Thomas Hood, C.M.G., and Major Gerald Bell, two of those originally connected with the movement, have made the arrangements for setting up the memorial in connexion with the London School of Tropical Medicine. The prize (about £30) is to be awarded triennially and is open to competition among officers of the West African Medical Staff, whether on the active or retired list. The award will be made in respect of the best paper written on one of the following subjects: (a) Tropical medicine or surgery (b) tropical hygiene and sanitation, (c) tropical entomology and parasitology. The first award will be made in 1924. Papers should be delivered to the Secretary, Seamen's Hospital Society, Greenwich, S.E., on or before October 1st, 1924.

THE ANNUAL MEETING AT NEWCASTLE.

THE Honorary Local Secretaries of the forthcoming Annual Meeting at Newcastle-on-Tyne are becoming anxious to know how many members they may expect, in order that arrangements may be made for the accommodation of visitors. It is particularly requested that early use may be made of the form of notification of attendance printed in this week's SUPPLEMENT, at p. 217. Detailed information about accommodation in hotels, hostels, and lodgings in Newcastle and neighbourhood was given in the SUPPLEMENTS of May 7th and May 21st.

DR. F. L. GOLLA will deliver the Croonian Lectures before the Royal College of Physicians, London, on Tuesday and Thursdays, June 9th, 14th, 16th, 21st, at 5 o'clock. The subject is "The objective study of neurosis."

WE regret to record the death of Professor Giorgio Ballerini, director of the school of obstetrics at Perugia, who served with distinction in the Italian army during the war.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Washington Labour Convention.

An animated debate took place on May 27th on a motion by Mr. Barnes that the conventions adopted at the International Labour Conference in Washington under the League of Nations should be submitted to Parliament.

Mr. Barnes's case was that the "competent authority" to which the conventions were to be referred in each country wherein a Parliament existed was Parliament, and that ministers had no right to decide whether or not ratification should take place. It appeared that three departments were concerned—the Home Office, the Ministry of Labour, and the Ministry of Health. The Home Office had given effect to three conventions touching the nightwork of women, the nightwork of young persons, and the age of admission of children to industrial employment. By the Women and Young Persons (Employment in Lead Processes) Act, 1920, effect was given to the recommendations as to lead poisoning. To the other three recommendations with which the Home Office had to deal—anthrax, Government health service, and the prohibition of white phosphorus matches—effect was already given. The Ministry of Labour and the Ministry of Health were interested in the remaining conventions—eight hours labour and maternity. Mr. Barnes explained that he did not vote for the last named recommendation, but he held, nevertheless, that all these conventions should be considered by Parliament.

Dr. Macnamara met the motion with an amendment asking the House to declare that in existing circumstances it was inexpedient to give legislative effect to the convention on hours of labour. He held (with the support of the Attorney General) that the "competent authority" to which all the conventions were to be referred to decide whether they should be ratified or not was the Government; but did not rest his defence on that ground. He suggested, in fact, that the eight hours labour issue could be discussed on his amendment, and said that the Government objection to the convention was that it cut across agreements made with trade unions. In regard to the refusal of the Government to ratify the maternity convention he quoted a reply made by Dr. Addison as Minister of Health, when the matter was raised on March 22nd. Dr. Addison then said that the proposals of the Washington Convention were that provision should be made for the six weeks preceding and the six weeks following confinement in employed women. This country had the Insurance Act, which provided maternity benefit for women who were themselves workers or the wives of employed contributors. Parallel with that, and administered by local authorities, was a system for giving assistance and advice in connexion with maternity and child welfare generally. These recommendations cut right across the whole of that system, which has been gradually built up in this country far in advance of any other country. Dr. Addison further said "Our system provides that not only the women employed, but the women who are the wives of employed contributors, although they themselves are not employed, shall also benefit. . . . These recommendations apply to about one ninth of the married women of a particular class in this country, and to one ninth only. But we have done something for the remaining eight-ninths."

Viscountess Astor thought this answer unsatisfactory and urged that this convention should be brought before Parliament. The object of the Convention was to protect women who through the illness of their husbands or through their husbands not getting sufficient wage were forced into industry and had to work up to the very last hour before their confinement, and had to get back perhaps in a week's time. It had been suggested that if the recommendation were adopted many women would go into industry before childbirth so as to get benefit. She did not believe they would do that if it could help it. She asked that the Minister of Health should consult a committee representative of women's societies.

Dr. Macnamara's amendment was carried by 109 votes to 69, but on further appeal he promised to give an opportunity for discussion of the reasons why the Government had declined to ratify the Maternity Convention or the Hours of Labour Convention; and that this opportunity should be afforded before the period for ratification expired, which he believed was in July.

Ministry of Pensions Medical Officers.—In reply to Lieut.-Colonel Croft, on May 30th, Mr. Macpherson said that, with the approval of the Treasury and after consultation with the Ministry of Health, the Ministry of Pensions had given a four years' contract, terminating on March 31st, 1925, to a number of full time salaried medical officers whose employment had previously been subject to one month's notice. Lieut. Colonel Croft asked whether the Minister of Pensions would undertake that the services of those doctors at present employed under the Ministry of Pensions who sacrificed their practices to join the army and navy at the outbreak of the war and were on active service, and are now dependent solely on their salaries, would be retained at the Pensions Ministry in preference to those who were already drawing big pensions in addition to their salaries and those who had never served abroad. Mr. Macpherson said that practically the whole of the full time medical officers of the Ministry served during the late war, and other things being equal, preference for retention would continue to be given to medical officers who saw active service over medical officers in the same class who did not so serve.

Public Health Officers' Bill.

This measure, which was introduced by Sir Philip Magnus, and recently obtained its second reading, was taken in Grand Committee of the House of Commons on May 26th.

Its object is to give to full time medical officers of health of local authorities and sanitary inspectors, security in tenure as is enjoyed by Poor law medical officers, metropolitan medical officers of health, and medical officers appointed by county councils. The term sanitary inspector covers "inspectors of nuisances," and is henceforth to be used in all cases. Sir Philip Magnus stated that an Order in Council already provided that medical officers appointed in the future should be protected from dismissal except with the Minister's sanction. Mr. Miles, for the Labour Party, supported the measure as in the public interest—namely, to strengthen medical officers in the performance of their duty by enabling them to discharge it without fear. He referred to the difficulty which otherwise was sometimes experienced in condemning an insanitary area. A new clause was inserted at the instance of Sir Kingsley Wood, for the Government to lay down that the bill should apply to medical officers and inspectors, whether appointed before or after the Act, but not to those cases where no grant was received from the Government. It was stated that these ruled out only about twenty-five authorities, mostly large, and in these the independence of the officers is practically secure in the size of the authorities. The bill was ordered to be reported to the House of Commons.

University and College Grants.—Mr. Hopkins asked, on May 26th, what were the principles and regulations under which the University Grants Committee was to recommend the distribution of the Parliamentary Grants recently approved by Parliament for the coming quinquennium; as it implied condition in the allocation of financial aid to University Colleges from the extra grant voted by Parliament, that they should obtain an equal financial assistance from local authorities; and was this principle also to be applied to grants made for the formation of clinical units in the hospitals, had the principle of giving building grants to University Colleges been authorized, and if so, what were the principles in which such grants were to be made, and was it intended to supply Government funds to raise the salaries of the more important professors in University Colleges to the same figure—namely, £2,000 per annum, as had been used for the salaries of the professors of the newly constituted clinical units in the hospitals. Mr. Young, Financial Secretary to the Treasury, replied that the general principles on which the University Grants Committee based their recommendations for the allocation of grants, were set out in the Report of the Committee dated February 3rd, 1921, and in the letter to Sir William McCormick, printed as an appendix to the Report. Great importance was attached to the amount of support provided from local sources in calculating the grants payable to the different institutions, but except in the case of the two University of Wales, there was no undertaking by the Government to make grants on the basis of pound per pound in respect of rate aid. The Committee were authorized to recommend capital grants for sites, buildings, and permanent equipment, if the funds at its disposition allowed, but no such recommendations had yet been made. The responsibility of fixing the salaries of the teaching staffs rested with the authorities of each institution.

Tuberculous Treatment.—Sir A. Mond, on an inquiry by Mr. Ronald McNeill, denied that regulations had recently been made with respect to the institutional and other treatment of tuberculosis, by county and borough councils.

Universities (Scotland) Bill.—Mr. W. Graham asked, on May 26th, whether the text of the Universities (Scotland) Bill, 1921, had been supplied to education and other bodies in Scotland; whether the bill had yet been presented to the House of Commons; and when Scottish members would be supplied with copies of it. The Secretary for Scotland replied that a Universities (Scotland) Bill was submitted to him with the approval of the University Courts of the four Scottish universities, but he was not aware if the bill in that form was considered by any education bodies other than the University Courts. He was considering the possibility of introducing a Universities Bill; that he had in view was substantially the measure of the University Courts. He feared that it would not be possible to make progress with such a bill this session, but he hoped that he might be able to introduce it so that its provisions might be considered by persons interested.

Milk Prices.—Mr. Baldwin, in answer to Colonel Newman on May 26th, said that the producers' average price for milk in May, 1920, was 1s 3d. a gallon; in May, 1921, it was 1s 2d. a gallon. The average retail price per quart in May of both years was 8d. A comparison of the figures was, however, fallacious for three reasons: (1) The milk trade was this year fixing a single retail price for the whole summer, and the May figures could not accordingly be taken as a basic standard of comparison, (2) wages had been increased in pursuance of the Trade Board award, and (3) there was a considerably increased loss on the portion of the supply converted into cheese.

Use of White Lead in Painting.—Lieut. Colonel Sir J. Gilmour (for the First Commissioner of Works) stated, on May 30th, in answer to Major M. Wood, that the practice of the Office of Works for the last fourteen years had been to use paints with a non-poisonous zinc base instead of a white lead base, and all contracts involving painting stipulated that no paint must contain more than 5 per cent. of soluble lead.

Fig 1—Roman wall looking east towards Housesteads.

EIGHTY-NINTH ANNUAL MEETING of the British Medical Association, NEWCASTLE-UPON-TYNE, 1921.

LOCAL ANTIQUITIES.

THE GREAT WALL.

SOME of the most interesting relics of the Roman occupation of Britain are to be seen in Northumberland, and they all centre round the system of fortifications known as the Great Wall. It is the stone wall and its supporting stations of which so much remains, but the system included an earth wall known as the Vallum, and other earthworks, military roads with bridges, mile-castles, turrets, stations, and townships which flourished under the protection of the great barrier and its garrisons. Remains which have been abundantly found in the district not only show the great military strength of this outpost of the Roman Empire, but indicate that at times the settled quietude of the exiles from sunny climes encouraged the establishment of refinement in living and the cultivation of the gentler arts. Kipling, in *Puck of Pool's Hill*, has given a vivid picture of what life on the Wall may have been, but the pilgrim, as he contemplates the vast ruins of man's pertinacity, grass-grown and solitary, must be impressed with the mutability of human affairs.

Cities and Thrones and Powers
Stand, in Time's eye,
Almost as long as flowers,
Which daily die.

The Great Wall stretched from Wallsend, near the mouth of the Tyne, to Bowness on the Solway, a distance of seventy-four miles. It represents, not the Roman frontier in the North, nor a fence to keep out the Picts and Scots, but a series of military posts linked together so as to enable the garrisons to assemble quickly at any one point either for attack or defence.

The outstanding feature of the Wall as a whole is its direct route across country, only deviating from the straight to take advantage of some strategic point, and

never fearing to skirt a veritable precipice or to dip straight into the deepest valley (Fig. 1).

The dimensions are estimated to have been 20 feet high, with a width of about 8 feet; while the fosse to the north was 30 to 40 feet wide and 12 to 15 feet deep. At one place is the ruined wall now more than 8½ feet high, and for the most part only a few courses remain, but in certain places the fosse has been better preserved, and is still probably of its ancient dimensions.

The structures that were formed for the accommodation of the soldiery who manned the wall consisted of stationary camps, mile-castles, and turrets. About every four miles there was a station. These were military cities, suited for the accommodation of the chief who commanded the district and the garrison under him. These stations are quadrilateral in form, and consist of a strong wall with fortified gates; the wall encloses an area of from three to five acres, on which the military offices, public offices, and houses were erected. Their position was often elevated and exposed, and some of them, as that at Housesteads, are in the wildest part of Northumberland.

In addition to the stations, Castella or mile-castles were distributed all along the wall at this distance from one another. They measured about 60 ft. by 50 ft., and were merely for the accommodation and protection of the soldiery. The turrets were little more than stone sentry boxes recessed into the great wall; three or four were placed equidistant between each mile-castle.

Visitors to Newcastle should take the opportunity of visiting one or more of the camps which are within easy reach of the city, for here can be pictured something of the life of the men who garrisoned the wall.

One of the largest and best preserved of these camps is at Cilurnum or Chesters, about eighteen miles by the direct road from Newcastle (station, Humshaugh, North British Railway). Here one may see the remains of the bridge across the Tyne, a Roman villa, and a museum of Roman antiquities, which is one of the best of its kind in the country.

Of the situation the Rev. John Hodgson has said: "The

* Previous articles on the history, institutions, and industries of Newcastle have appeared in the BRITISH MEDICAL JOURNAL of December 11th, 1920, p. 902; March 12th, 1921 p. 391; and April 16th, 1921, p. 577.

FIG 2—Roman street at Chester.

Astures, in exchanging the sunny valleys of Spain for the banks of the Tamey Tyne, might find the climate in their new situation worse, but a lovelier spot than Cilurnum all the Astures could not give them."

The camp is situated on the banks of the North Tyne. It is rectangular in shape, but with six gateways instead of the usual four. The Wall comes up to the eastern gateway and passes on from the western side of the camp. The gateways here still show ruts worn by chariot wheels;

statuary, vases, gems, coins, rings, and so forth, which have been found during excavations on various parts of the Wall.

The camp at Housesteads (Borricovicus), five miles further on, contains a temple dedicated to Mithras, the Sun God of Persia. About two miles to the south, at Chesterholm, a Roman milestone is to be seen still proudly standing upon the line of the Stanegate (fig 4).

The largest station is at Burdowald, near Gilsland in

FIG 3—Remains of the Roman bridge at Chester

and the tramp of feet passing to and fro, the heating chambers when opened out in 1843 still contained soot, and the bath was coated with red cement. The market place, with its public buildings, the treasure house and the Governor's residence, give the visitor plenty of material for his imagination to build upon (Fig 2).

A hundred yards away is the river with the remains of the Roman bridge which spanned it at this point, and which Dr. Collingwood Bruce considered the most remarkable feature on the whole line of the wall (Fig 3). In the museum are preserved numerous altars, inscribed stones,

Cumberland, on the main line between Newcastle and Carlisle.

It is impossible in so short a space to do anything more than briefly mention some of the most interesting features of the Wall. The visitor must see something, no matter how little, to realize the magnitude and the grandeur of this work. An excursion is being arranged in connexion with the meeting, to visit Chester and the Wall in the neighbourhood, and no one who is not already familiar with this vast monument of Roman greatness should miss the opportunity.

PLACES OF INTEREST IN THE
NEIGHBOURHOOD.

Excursions are being arranged to visit some of the following places of interest in the neighbourhood of Newcastle-on-Tyne, all of which have taken a large share in the making of history in the "north countree."

Alnwick, the old county town of Northumberland and the seat of the Duke of Northumberland, lies thirty miles north of Newcastle: now a peaceful border town, but once a disastrous spot to the Kings of Scotland. The Abbey and the Castle contain much of interest. The bridge over the Aln with the Percy Lion with outstretched tail is a conspicuous feature not easily forgotten.

Morpeth, fourteen miles north of Newcastle, is a picturesque market town dating back to a remote period. The Castle, which was built shortly after the Conquest, stands on an eminence just above the main road leading into the town from the south. In the market place is the Town Hall and the Clock Tower, containing the bells of the town, on which the curfew is still rung nightly. About one mile to the west, on the banks of the Wansbeck, are the remains of Newminster Abbey, destroyed after the dissolution of the monasteries, and recently partially restored. Another mile in the same direction brings us to the remains of the Norman castle of Mitford.

Hexham, twenty miles west of Newcastle, is the centre of a district full of interest. The town itself is of Roman origin; on a terrace overlooking the valley of the Tyne. The beautiful old

Abbey Church is said to form a veritable textbook of the Early English period of church architecture, and the Crypt, built of Roman stones, is of special interest. The Moot Hall and the Manor Office are two ancient buildings in the Market Place at Hexham.

Blanchland, about ten miles south of Hexham, figures much in Sir Walter Besant's historical novel of *Dorothy Forster*.

Tynemouth is situated on the north side of the mouth of the river, with its Castle and Priory forming prominent features. From here northward to Whitley Bay the cliffs are bold. This part of the coast is "Newcastle-by-the-Sea," and is within easy reach of the city by electric train. At South Shields, which stands on the south bank of the river opposite Tynemouth, is a Roman Camp.

Jarrow, on the south side of the river, midway between Newcastle and the sea, is famous apart from its industrial renown, for it is the home of the monastery in which the Venerable Bede, the head of the most famous school of learning in Europe, lived and laboured and died (673-735).

Durham is fourteen miles south of Newcastle, and is the capital town of County Durham. It is famous for its magnificent cathedral, unrivalled alike in situation and in architecture. The Castle is now

the centre of the University, with its Colleges of Medicine and Science situated in Newcastle.

A Convocation is to be held at the University of Durham during the meeting of the British Medical Association, and members will have the opportunity of being present at the ceremony.

England and Wales.

PAYING PATIENTS IN BRISTOL HOSPITALS.

At the Royal Infirmary and General Hospital, Bristol, arrangements have been made for the admission of paying patients. After preliminary discussions, which lasted for more than a year, the committees and medical staffs of the two institutions agreed upon an identical scheme. This scheme was approved by the governors of each charity at general meetings held on May 25th and 26th. It provides that all in-patients able to do so shall pay up to 1 guinea a week towards the cost of their maintenance, that out-patients shall pay a small fee for each attendance, and that almoners shall be appointed at each institution. The rules of each charity, that such persons only shall be admissible as are unable to pay for medical advice and treatment, remain in force and have been reaffirmed. The following resolution was submitted by the honorary staff of the Royal Infirmary to the committee and governors:

In order to enable the governors to bring into operation the proposals for the admission of paying patients, the honorary staff desire to offer their gratuitous services to all patients who are found after inquiry by the almoner to be unable to pay more than the cost of their maintenance. But in the case of patients whose payments are defrayed by public authorities or approved societies, the honorary staff will attend and treat such patients in consideration of an agreed percentage of the gross payment received by the Royal Infirmary and to be paid into a fund which shall be at the disposal of the honorary staff.

At the meeting of the governors of the Bristol General Hospital the honorary staff made verbally a similar offer of their services, excepting that they were not prepared to go so far as to attend gratuitously all patients who might be able to pay the whole cost of maintenance. The issue is not in itself of much moment; it is of considerable importance, however, to have a "contract of service" between hospital governors and staff so clearly defined with a view to present and future developments in hospital management and finance.

SCHOOL OF NURSING AT THE LEEDS INFIRMARY.

When the original part of the present infirmary buildings, with its five ward pavilions and... was opened in 1868 by King... Wales, it is said that the number of nurses employed at the infirmary was only 20, and the accommodation for even that small number appears from the plans to have been singularly inadequate. The original nurses' home was added in 1880 and... in 1895. The enlargement of the infirmary... other accommodation being secured, and the new nurses' home was opened in 1898. In 1907-8 it was again found necessary to increase the staff, and temporary but very satisfactory accommodation was secured by adapting some houses which had come into the possession of the infirmary in connexion with the purchase of the land for the King Edward Memorial Wing. The nurses now number about 170. Of late years a great deal has been done to systematize the training of the nurses, to widen their experience, and to

afford those who show special aptitude every facility for acquiring those branches of knowledge which are necessary for the proper carrying out of the duties of matron or superintendent. Candidates for training must be between the ages of 20 and 30; they are all appointed by the board on the recommendation of the lady superintendent, who interviews those who apply. They are admitted as pupil nurses for three months' trial, six to eight weeks of which are spent in the preliminary training school. During this period they receive lectures in elementary anatomy and physiology from the professors of these subjects at the university or from members of their staffs, and they also attend lectures on practical nursing and sick-room cookery. Before entering the wards they have to pass a satisfactory examination in the work they have done during this preliminary stage. In their preliminary training they are under the personal supervision of a special sister tutor and receive tutorial instruction from her. At the end of this period of special probation, if they are found to be satisfactory and likely to prove efficient nurses with training, they are, after a physical examination conducted by a member of the honorary staff, admitted to training in the hospital, and are required to remain in the service of the hospital for twelve months from the date of their beginning their preliminary training. If they desire to continue their training, and are approved, they then sign on for a further period of three years, so that at Leeds the training extends over a term of four years and no nurse now gets her certificate on a shorter curriculum. The institution of the preliminary term of training has proved a great success. It has shortened the time it takes to make a nurse of real use; it gently eliminates those who are not likely to make efficient nurses, and it lays the foundation for a more accurate and scientific acquaintance with the different departments of nursing.

During the hospital training lectures are given to first year's nurses on practical nursing and bandaging and on anatomy and physiology, to second and third years' nurses on surgery, medicine, and on ophthalmic and aural work, and during the third and fourth year on midwifery and gynaecology and on hygiene. The hospital certificate is awarded on the results of a terminal examination and on the report of the character of the nurse's work as evinced by term examinations and testified to by those under whom she has worked. Twenty scholarships providing free training for the certificate of the Midwives Board are given annually to selected nurses during their final year; class prizes are awarded also. During the fourth year the nurses receive the title of Staff Nurses, and from these promotions are made by the board, on the recommendation of the Lady Superintendent, to the position of "Sister" (15 Heads of Wards, Casualty and Out-patient Sister, and Theatre Sister). Four of the staff nurses are selected yearly to receive special training in housekeeping under the Lady Superintendent and her deputies. The training at Leeds is now believed to be of the highest standard. The comfort of the nursing staff has been the subject of sympathetic thought on the part of the board; the salaries have been increased, the time for recreation has been extended, and tennis courts have been provided by the kindness of the late Mr. Frank Gott, whose recent death is greatly regretted by his colleagues on the board as well as by everyone connected with the infirmary.

A further step will in all probability shortly be taken by which it is hoped that the University of Leeds will grant diplomas in nursing. The regulations are being very carefully drawn up and scrutinized, and it would not be right at present to say more than that both the University authorities and those who advanced the scheme in the first instance are keenly alive to the advisability of maintaining a high standard of general education and of technical training and knowledge. When the scheme is decided upon by the University the details will be given in this column.

COUNTY MATERNITY HOME AT BISHOP AUCKLAND.

The first County Maternity Home under the Durham County Council was opened recently at Bishop Auckland. Dr. Janet Campbell, chief maternity and child welfare medical officer at the Ministry of Health, was present, and congratulated the county on its excellent maternity and child welfare work. She said that there

were still far too many maternal deaths from childbirth, and although death did not often result, many mothers were crippled in health for years afterwards through unskilled attention. There was a great need for small maternity homes of this type, and the Treasury had realized this, and had permitted the Ministry of Health to expend money on such beds when it refused grants for other schemes for maternity and child welfare. Councillor Barron, who was the recipient of a presentation in appreciation of his help in furnishing and equipping the home, referred especially to the fact that the preference in beds would be given to mothers whose home conditions were unsuitable for confinements and to those with complications in pregnancy, but, if beds were available, patients able to pay the full charge of three guineas a week would not be refused admission.

The County Maternity Home is to be managed by a joint committee consisting of members of the Maternity and Child Welfare Committee and of the County Nursing Association. The county medical officer acts as executive officer, and the senior welfare medical officer as advising medical officer of this committee. Any patient who so desires may be attended by her own doctor. Where no doctor has been engaged the matron will conduct the labours, but to ensure adequate medical attendance a rota of doctors resident in Bishop Auckland has been arranged; each will act for three months at a time, and if the acting doctor is not available the next on the list will be summoned. One of the welfare medical staff of the County Council will visit the home twice weekly and give the necessary lectures to the midwives when the home is approved as a training school. The home is a modern three-storied house, and it has accommodation for seventeen mothers and babies, and a resident nursing staff. Arrangements have been made for the training of midwife pupils, and already several patients have been admitted to the home.

HEALTH OF LONDON.

The report of the medical officer of health to the London County Council for the year 1919 has just been issued. The general arrangement follows very much the lines of previous reports, and a document dealing with the concerns of over four million persons, and with the varied and various public health enterprises of the present day, cannot but contain many matters of profound interest not only to the hygienist but to the general public. The earlier pages are concerned with vital statistics, the incidence of infectious disease, and the public health administrative activities of the County Council. The chapter dealing with the school medical service is attractive because it recounts the gradual return to normal conditions of a vast public service which, during nearly five years, had been endeavouring to carry on its work with a largely reduced staff and with the public purse-strings gradually tightening. Included in the appendices is a detailed report by Dr. F. N. Kay Menzies, Principal Assistant Medical Officer in the Council's Public Health Department, on the arrangement for the treatment of tuberculosis in London, and a memorandum on the treatment of tuberculosis presented to the Insurance Committee for the County of London by their medical adviser, Dr. Noel D. Bardswell. We propose to make more extended reference to this report of Dr. Hamer in a later issue of the JOURNAL.

MEDICAL DEPUTY-LIEUTENANTS FOR LANCASHIRE.

The following members of the medical profession have been appointed Deputy-Lieutenants for the County Palatine of Lancaster: Sir James Barr (Liverpool), Mr. Arthur H. Burges (Liverpool), Mr. J. D. Donald (Manchester), Dr. T. (Liverpool), Dr. John Hay (Liverpool), Sir Robert Jones (Liverpool), Dr. C. J. Macalister (Liverpool), Dr. G. R. Murray (Manchester), Mr. R. W. Murray (Liverpool), Dr. George Parker (Bolton), Dr. E. S. Reynolds (Manchester), Dr. Alexander Simpson (Warrington), Mr. J. W. Smith (Manchester), Sir William Tibbatts (Manchester), Dr. C. J. Trimble (Penwortham, near Preston), Dr. John Utting (Liverpool), Mr. F. H. Westmacott (Manchester), Dr. Alexander Wilson (Manchester).

Ireland.

MEDICAL MEMBERS IN THE ULSTER PARLIAMENT.

THREE medical men have been returned as members of the Ulster Parliament; they are three of the four representatives of the Queen's University of Belfast; no medical men stood for any of the other constituencies. The voting for the university representatives stopped at 5 p.m. on May 28th, and at 8 p.m. the returning officer (the Vice-Chancellor) announced that the four successful candidates were Dr. John Campbell, F.R.C.S. Eng., Mr. R. J. Johnstone, F.R.C.S. Eng., Mr. John H. Robb, barrister, all of Belfast, and Dr. Hugh S. Morrison of Coleraine, co. Derry. There were three counts.

THE ULSTER MEDICAL SOCIETY.

The annual meeting of the Ulster Medical Society was held at the Ulster Medical Society Institute, Belfast, on May 26th, with the President, Dr. Thomas Houston, in the chair. The council's reports were read by the secretary, the treasurer, and the librarian, and passed with slight amendments. The following office-bearers were elected for the ensuing session: President, Dr. Robert Hall, Belfast; vice-presidents, Mr. James C. Craig, Belfast, and Dr. G. L. St. George, Lisburn; council, Professor Lowry, Mr. Howard Stevenson, Dr. W. Burns, Dr. V. G. L. Fielden, Dr. S. B. Boyd Campbell, and Dr. Maitland Beath, all of Belfast; honorary treasurer, Dr. S. I. Turkington; honorary librarian, Dr. W. L. Storey; honorary secretary, Dr. W. W. D. Thomson; honorary editorial secretary, Dr. R. Marshall. A resolution of sympathy was passed with Dr. W. W. D. Thomson in his prolonged illness, and Dr. Marshall was thanked for his able discharge of the double duties. A prolonged discussion took place on the honorary treasurer's statement of accounts, as they showed a serious increase in the annual deficit, which had been small but increasing in past years; the general upkeep had been interfered with and some pressing repairs to the building were required by the trustees. It was finally agreed that a request, accompanied by a copy of the statement of accounts, be sent to all fellows and members, asking them to increase their subscriptions voluntarily by at least 50 per cent. for the ensuing year. Should this appeal fail, it would, it was thought, become necessary to raise the subscription to the society, though this would be done with great regret.

SIR PATRICK DUN'S HOSPITAL ROLL OF HONOUR.

Sir Patrick Dun's Hospital, Dublin, has cause to be proud of the honours which her old students won in the great war, for the 418 past and present students who served gained no fewer than 244 distinctions. The Roll of Honour, which contains the names of the old students and their distinctions, has just been published, and is accompanied by a photograph of the war memorial which was unveiled in the hospital last December, as was noted in our columns at the time. The memorial was erected at the exclusive cost of the survivors of the 418, and in addition a memorial bed was endowed in the hospital. On the memorial are the names of thirty old students who laid down their lives, including the following medical men:

Lieut.-Colonel Sir Charles B. Ball, Bt., Lieutenant W. O. W. Ball, Captain A. C. Bateman, M.C., Fleet Surgeon H. L. Geoghegan, Lieutenant H. R. Griffith, Colonel William Hallaran, Lieutenant F. G. Hopkins, Major P. G. Hyde, Captain Kingsmill W. Jones, D.S.O., Major J. T. McEntire, Légion d'Honneur, Captain E. J. McSwiney, Captain H. R. Robertson, Captain Edmond Robertson, Captain C. G. Sherlock, Major R. S. Smyth, Lieutenant George Taylor.

THE next meeting of the French Orthopaedic Society will take place this year on October 5th at Strasbourg, when discussions will be opened by MM. Froelich (of Nancy), Ombrédanne (of Paris), and Tavernier (of Lyons).

THE Ophthalmological Society of Vienna announces an extraordinary meeting to be held from August 4th to 6th. On the first day a discussion will take place on the success of the latest operation for glaucoma compared with the classical Von Graefe iridectomy, to be opened by Drs. Uthoff and Wessely; other scientific meetings and demonstrations will be held on the following days. The secretary of the meeting is Dr. M. Lauber, Aiserstrasse, Vienna VIII.

Correspondence.

THE FUTURE OF RESEARCH IN TROPICAL MEDICINE:

Facilities in Mauritius.

SIR,—Here in the island once known as "the Star and Key of the Indian Ocean," but now unfortunately possessing the unenviable notoriety of being the most unhealthy of British colonies, I read with much interest the account of Sir Leonard Rogers's address on the above subject in the JOURNAL of March 12th. He has unfortunately been misinformed as regards British East Africa, where, at Nairobi, a laboratory has existed for years, and where, long before the war, good work was done by Philip Ross, Harvey Pirrie and others. This laboratory, however, is poorly housed, and a new building is to be erected which will contain special rooms for research workers, apart from the accommodation provided for the staff.

Few, I think, who know the tropics but will agree wholeheartedly with Sir Leonard Rogers's arguments and plea for help. In Mauritius there is a case in point, though Mauritius is more fortunate than many places, for since August, 1907, it has had the benefit of an excellent little laboratory situated at Réduit. The building on the whole is well equipped, and is under the able direction of Dr. L. G. Barbeau, an old student of the London School of Tropical Medicine and of the Pasteur Institute, Paris. Unhappily he is hampered in his work, for he is understaffed and has to carry out many duties which should not fall to his lot. Furthermore, the laboratory is, unfortunately, situated far away from any large centre of clinical work. It is eight miles from Port Louis, the capital, where there is a big civil hospital, and it is a considerable distance from the new central hospital now in process of erection at Candos. The only hospital anywhere near it is that which serves the Moka district, and which chiefly admits surgical cases. This is certainly a drawback, but the disadvantage is to some extent minimized by the fact that the island possesses capital roads, and material can speedily reach the laboratory by motor car. Doubtless the present site was selected because Réduit is much cooler and healthier than Port Louis, but there can be no doubt that, for purposes of research at least, it would have been wiser to attach this laboratory to the civil hospital in the capital, where it could also have readily served the needs of the Port. Still, as it is intended to meet the requirements of the whole island in some respects, its position is suitable.

The history of the institution is interesting. It owes its origin largely to the energy of a well known Maurician, Sir Henry Leclézio, K.C.M.G. He it was who induced a French army surgeon, Dr. Lafont, to leave Réunion and become the first director of the laboratory in Mauritius. Under Lafont the laboratory did good work, and indeed gained a measure of fame owing to the discovery by David, one of Lafont's assistants, of the flagellate of the Euphorbia, now known as *Leptomonas davidi*, a discovery which has had an important bearing on certain problems in protozoology. In 1911 Lafont left Mauritius, and Dr. Barbeau, in addition to other duties, supervised the work of the laboratory. In 1914 he was confirmed in the post of director. He has maintained the reputation of the laboratory, the services of which are in great request. As a result Dr. Barbeau and his few assistants are overwhelmed with routine work of all kinds, though praiseworthy attempts are made to conduct research, and though useful observations have been recorded it is wellnigh impossible at present to make much progress. Yet what a field of work is presented by Mauritius! The incidence of filariasis has never been ascertained; the actual mosquito vector of *Filaria bancrofti* remains unknown; despite serious efforts by Dr. Mompole and Mr. Maya, the snail host of *Schistosomum haematobium*, the only human schistosome found here, has not been discovered.

There is a fine opening for entomological research in several directions, and it is possible that undifferentiated fevers exist. Surra occurs, but the fly which transmits *T. evansi* in Mauritius has not yet been determined.

A recent report by Dr. Kendrick, of the Rockefeller Foundation, has shown that ankylostomiasis is exceedingly prevalent. He estimates that no less than 225,000 persons

in the colony are infected, and in one district—that of Moka, in which the laboratory is situated—90.6 per cent. of the inhabitants harbour the helminth. Other worm infections are exceedingly common, and so, be it noted, is appendicitis.

From the hygienic point of view the resources of the laboratory could be utilized in many directions, and they must be so utilized if the island is to be made healthy. Much yet remains to be done as regards the incidence of malaria. Major Fowler's suggestion as to the necessity of further research into the rôle of *Anopheles mauritians* as a carrier has never been acted upon. The precise value of the spleen index test requires to be determined, and the causes, apart from malaria, which induce splenomegaly should be the subject of careful inquiry. These are but a few of the questions which await the research worker here.

Mauritius is a good place for the pursuit of science. It is isolated, but there are few distractions. It possesses in some degree the peaceful atmosphere which is so favourable to research. It is small, the size of Surrey, and yet as full of problems and pathological conundrums as an egg is full of meat. Its leading medical men are well acquainted with the existing conditions, and would, I feel certain, welcome keen research workers from home. As is usual in these latter days, our good friends, the Americans, have been before us. What Dr. Kendrick thought of the sanitary condition of the island, and more especially of its capital, I can only imagine. Yet progress in sanitation must always be largely dependent on research in the laboratory. When are we going to wake up?—I am, etc.,

ANDREW BALFOUR.

Port Louis, Mauritius, April 30th.

THE TREATMENT OF ACUTE TOXAEMIA.

SIR,—The cells of many types of living beings, unicellular and multicellular, secrete poisons—endotoxins for defensive and exotoxins for offensive purposes. The microbes of disease, insects, snakes, and numerous plants furnish examples. All our vegetable medicines are endotoxins which, by means of poisonous action often combined with disagreeable taste, protect the producing plants from animal enemies. In chronic diseases—for example, tuberculosis and leprosy—the poisons are mainly endotoxins; in acute diseases—for example measles, pneumonia, diphtheria, septicæmia—they are exotoxins. Fever is a reaction to toxæmia.

While experience of some poisons—for example, strychnine, quinine, and tuberculin—confers little or no added power of resistance, it is possible to train the individual to increased tolerance of other poisons—for example, nicotine, opium, snake and insect venom, and the toxins of the acute diseases. It is unnecessary to discuss the vexed question as to how this tolerance arises; bacteriologists have formulated many suppositions; but presumably it is in essence what biologists call "an acquirement," a product of functional activity, an habituation. The individual becomes "used" to, accustomed to, educated to toxins, and in recovery from acute disease his cells, no longer poisoned to impotence, are able, as a consequence, to attack and destroy the pathogenic organisms. Hence recovery and acquired immunity, temporary or permanent.

This habituation may be achieved in three distinct ways:

1. By beginning with small and proceeding to larger and larger doses of toxin, as in tobacco and opium smoking, and when diphtheria toxin is administered to a horse during the manufacture of antitoxin.
2. By beginning with and maintaining in action one large dose, as happens in acute disease which is followed by recovery.
3. By antitoxin and vaccine treatment, the rationale of which, as I say, need not be discussed.

The second method is exceedingly dangerous, and is the cause of death in disease. The last method has been attempted in many infections, but as yet it has been conspicuously successful in only a few acute diseases—for example, diphtheria and small pox. Were it possible in acute illness to combine antitoxic serum with small doses of toxin, we should have an ideal method of cure. But serums for many acute diseases are lacking.

Moreover, in illness the patient is already suffering from a large dose of toxin, which the introduction of small doses from outside would only make larger. Consequently, during illness, the only conceivable method of causing a sufferer to experience small doses is to reduce the amount of toxin in him. I do not know that this has ever been consciously attempted. I believe, however, it is not impracticable. In other words, I believe it is possible to abstract toxin from a sufferer.

Consider lobar pneumonia. A portion of the lung is invaded by the pathogenic organisms; blood is extravasated; and that portion of the lung becomes more or less solid. The temperature rises, rigors occur, the patient suffers from headache, sleeplessness, and a general feeling of illness. The severity of the disease is not at all strictly proportionate to the amount of lung involved, but depends rather on a toxæmia which especially affects the heart and breathing centres. In favourable cases a "crisis" occurs about the fifth to the tenth day. Commonly the patient sleeps, and awakes some time later feeling much improved. His temperature has fallen, his headache, rigors, and sleeplessness have gone, and he is bathed in sweat. Apparently the condition of his lung has not altered; but later gradual resolution occurs, and the extravasated and disintegrated blood is voided as "rusty" sputum.

Sweating is Nature's mode of cooling the healthy body by evaporation from the surface. But if, as usually happens, in pneumonia, the patient is thickly covered with bedclothes and evaporation prevented, the temperature still falls. Presumably, therefore, something more than mere exudation and evaporation of fluid occurs in the crisis—something which in itself causes the fall of the temperature and the general improvement. I can conceive no reason for such a sudden change except a quick elimination of toxin, and, in view of the lack of evidence of increased activity in other possible channels of elimination, I cannot conceive by what road the toxins can be pressed out if not by the sweat. I know of no evidence that toxins have been found in the sweat; but then, I do not know that they have been sought there.

Since recovery from acute diseases is associated with a falling temperature, moisture of the skin, and sleep, the administration of antipyretics, sudorifics, and soporifics was formerly common. But the medicines and the dosage generally employed depressed the heart and breathing centres, and of late it has been regarded as almost axiomatic that antipyretics and sudorifics are injurious under such conditions.

But if we give a patient, suffering from pneumonia, for example, and not already poisoned past redemption, the following dose, aspirin 10 grains, phenacetin 5 grains, and pulv. ipecac. co. 5 grains, we get (as far as my experience goes) what has all the appearance of an artificial crisis, without depression of the heart and breathing centres, or any other ill effects. The patient soon falls asleep, and wakes up some hours later feeling much better, bathed in sweat, his temperature down, his rigors and headache gone, and his pulse and breathing improved. The signs of illness will gradually return, but they can be abolished in the same way once or twice a day till permanent improvement sets in. On such occasions the patient will be relieved and rested, and, unless my experience has been unusual, his illness shortened.

Lately I myself fell ill of lobar pneumonia. I began the treatment I describe about the third day, having previously received ordinary treatment, but I know no good reason why I need have waited so long. My most vivid recollection is the immense and blessed sense of relief that followed each dose. I fell asleep within half an hour. After waking I was able for some hours to read or converse with comfort—indeed, with little feeling of illness. I suppose I took six or seven doses in all. Within a week I was writing at my desk. On the tenth day of illness I was taken for a thirty miles motor drive in the country. On the twelfth day I was walking about visiting friends at their own houses. On the thirteenth day I was back at full medical work, feeling none the worse. I am not young. I voided not rusty sputum but bright blood, showing rapid resolution. As well as I am able to judge, at each artificial crisis toxins were eliminated in large quantities, and the body was thus presented with several small doses, instead of having to make head against one continuously large dose. Certainly while my temperature was high I felt poisoned; during the intervals I felt, or seemed to feel, relief from poisoning. Apparently my sweat centre was roused to activity, while my heart and breathing centres were relieved by the elimination of the toxin.

I have never known ill results follow this treatment, though it has been tried lately in a fair number of cases, both by myself privately and by friends in hospital practice. The following is a fair sample of cases:

Lobar pneumonia (advanced stage). No improvement followed treatment. Death. Apparently the patient was poisoned beyond redemption.

Lobar pneumonia (early stage). The temperature was taken as a guide and several doses given. This case followed a course very similar to that in my own illness. Patient was up and about on the tenth day.

Bronchopneumonia following suicidal immersion. Only one dose was given. Sleep; sweating; temperature fell, and never rose again. Recovery, but "vast quantities of sputum were voided for four days."

Mild rheumatic fever. Some temporary relief followed each dose, but apparently no permanent improvement, though treatment was long continued. But aspirin has been found very useful in this disease. How does it act? Hardly as an antiseptic.

Diphtheria. Twenty thousand units of antitoxin given about the same time as the dose. Sleep; sweating. Patient awoke declaring himself recovered. Temperature never rose again. No further treatment necessary. Presumably, in this case the toxin had been eliminated. That is, serum treatment was combined with a small dose of toxin.

Measles in child of 6. Beginning of eruptive stage. Severe photophobia; diarrhoea; cyanosis, so that mother remarked on "white appearance about the mouth." Temperature 103°. Dose (1/6 adult) given. Patient passed a good night. When seen next morning was sitting up playing happily in bed. Slight cough; rash fading. Temperature normal; no diarrhoea, cyanosis, or photophobia. Immediate recovery.

Two cases of measles; average severity. Doses given. One child much and the other little improved next day. Two more doses given. Both children nearly recovered that day.

Threatened breast abscess a week after childbirth. Temperature 101.5°; sleepless; acute headache. Bad mental condition. Dose given. Slept; sweated; awoke feeling much better in mind and body; temperature normal. Threat of abscess gone. No further treatment.

Diphtheria. Only one dose given, which apparently had no effect, good or bad.

Enteric fever. Only one dose given, which apparently had no effect.

Septic infection of ureter. Rigors; temperature 105°. Effect of doses as in my own illness. Quick uncomplicated recovery in a week.

Two cases of *pyrexia of uncertain origin*. One dose given. Sleep; sweating; recovery.

These are sample cases. Up to now the suggested treatment has apparently given such good results in many cases that I have hopes that it will prove generally useful in the treatment of acute toxæmia—for example, in puerperal fever, surgical sepsis, tetanus, small-pox, and the like. But medicine is full of decaying mare's nests. It is never wise to trust to the experience furnished by a few cases to a few men. I venture, therefore, to ask if some of your readers, medical and surgical, will try this treatment, and either publish their results or inform me of them. Obviously, even if the treatment be useful in some acute diseases, it is sure not to be useful in others; the combination of drugs I suggest may be improved on; there may be a right and a wrong stage in each disease for the commencement of treatment, and so on.

I suggest that in every instance the trial shall begin by giving a single dose in a single suitable case. If the results are not unfavourable, the treatment may be continued and the experiment extended. My own experience has been such that I feel very confident. But that, I suppose, is the way of all beginners. It should be noted that I suggest an addition, not an alternative, to ordinary treatment. The extreme simplicity of the suggested addition is liable to create scepticism; and though simplicity does not always imply inefficiency, unfortunately it often does. However, the test and perhaps the improvement of this "reduction" treatment is easy.—I am, etc.,

Southsea, May 20th.

G. ARCHDALL REID.

THE SITE OF OPERATION FOR EMPYEMA.

SIR,—Selection of the most suitable site for rib resection is not governed by definite rules, but depends on the situation of the collection of pus. For a general pyothorax or pyopneumothorax the authorities which I have consulted—British, French, and American—with one exception, prefer the eighth or ninth rib, just external to the angle of the scapula, with the arm horizontal—that is, at the most dependent attainable part of the cavity. Resec-

tion for encysted or localized empyemata should be—when x rays are not available—as near as possible to the mark of the lowest successful exploratory puncture. The technique of the operation and subsequent treatment are probably of more importance than the position of the incision, and a brief summary of the notes of 78 cases of pleural suppuration with resection under my care in Franco during 1917 and 1918 may be of interest.

Thirteen of these were unwounded, such 'empyemata' as we meet in civil practice, and as, with one exception, the explorations or x-ray findings had indicated the ordinary site, this was chosen, and the results proved satisfactory, though in two cases it was found necessary to break down adhesions with the finger a couple of days later in order to set free loculated collections. The after-treatment differed from that described in the textbooks in that the lavage which they condemn was always employed, unless such complications as bronchial fistula or pulmonary abscess forbade.

My notes on the 65 resections for empyema or pyothorax following penetrating wounds of the chest confirm the good effects of irrigation especially by Carrel's method, but here a far more virulent infection was encountered. In many cases a sudden and extensive pneumothorax was the first indication of the presence of *Bacillus welchii* and immediate resection was the only course. A Turner's tube now and then relieved the extreme urgency, but in two only averted the need for a larger opening. The deaths, of which I have unfortunate record of twelve, were due to complications not likely to be met with outside military surgery, but the causes of three are of particular interest. The first of these was apparently doing well when seen in the morning, but in the afternoon developed a huge left pneumothorax from gas-bacillus infection, the heart being completely dislocated to the right side. Operation half an hour earlier might have saved the life.

Resection in the other two was soon followed by surgical emphysema, which rapidly spread from chin to hip, but ceased to increase on readjustment of the tube. This complication also happened in two non-fatal cases, and we were quite unable to explain how a positive pressure was set up sufficient to force air among the connective tissues. Such an accident might conceivably occur in civil practice. So many of the remainder were similar to empyemata of non-traumatic origin that the knowledge acquired in their treatment may well be applied to our ordinary work. In the first place, the utility of x rays in localizing pus must be emphasized. Gregoire is very definite:

"Exploratory puncture enables us to establish the existence of pus and the point where it is present, but it cannot tell us the limits of the collection. The surest way of ascertaining the site and lower limit of the cavity is incontestably puncture with a trocar guided by the radioscopic screen."

Secondly, I would like to record the excellent results that followed irrigation by Carrel's tubes. In localized collections the method of insertion is similar to that employed with deep septic wounds, but for a general pyopneumothorax the tubes are "armoured" with a silver stylet and their correct position ascertained by x rays. For the former three or four tubes are sufficient; for the latter as many as eight or nine may be required. The original intention was to reduce the infectivity of the pus to such a level as would permit of reclosure of the wound, and thus avoid extensive adhesions and promote early expansion of the lung. Frequent examinations of the number of organisms in a field were made, but only in two cases was the original aim attempted, and one of these had subsequently to be reopened. The ideal of Tuffier and Depage failed, but the early clearance of pus, the dissolution of purulent flakes, the ease to the patient, and the rapid general improvement were remarkable.

Thirdly, it must be remembered that cure is only complete when the lung returns to contact with the parietes, and every effort must be made to promote its expansion. Breathing exercises, whistling and playing wind instruments, are not willingly carried out by the resected nor cheerfully borne by their neighbours, but spiropneumocopy and suction methods of reducing intrapleural pressure should be employed wherever possible.

Fourthly, the benefit of open air and sunlight cannot be over-estimated.—I am, etc.,

Westcliff-on-Sea, May 23rd.

T. B. SELLOPS, M.D.

VITAMINS AND DENTAL CARIES.

Sir.—There are indications that the fat-soluble A theory of the causation of rickets is not satisfactory, and if the experiments of Professor Noel Paton and Mr. A. Watson (BRITISH MEDICAL JOURNAL, April 23rd) have not demolished this vitamin theory, they must at least have tempered the enthusiasm of its advocates. Naturally, Professor E. Mellanby (BRITISH MEDICAL JOURNAL, May 28th) does not abandon the theory, and even adopts the idea that lack of fat-soluble A in the diet is the "all-important factor" in the causation of dental caries! The contention that defective calcification of the teeth is responsible for the prevalence of dental caries is not new. It was, however, set aside by the dental profession years ago, after the late Professor G. V. Black's classic investigation into "the chemical and physical properties of the teeth" left no other course open. Having made an extensive chemical and physical examination of teeth, Black came to the conclusion that—

"the teeth of persons who suffer much from caries are just as hard, just as heavy, and contain just as much lime salts as the teeth of persons who do not suffer specially from caries."

In different teeth there are certain differences. Sir Charles Tomes gives the percentage of lime salts for the incisors as 71.5, and for the molars 73.2. These figures are practically the same as those recorded by Black, and more recently by Gasman. Yet, as is well known, the molar teeth are more frequently ravaged by caries than are the incisors. With regard to the microscopic structure of the teeth, Dr. Leon Williams showed years ago that—

"the finest lenses reveal not the slightest difference between enamel ground moist from a living tooth and that which has lain in the earth for a hundred centuries."

If fat-soluble A had anything to do with the prevalence of dental caries, why should we find that it increased with the increased consumption of such foods as butter, eggs, and animal foods. Together with an increasingly higher standard of living last century there was a corresponding increase of dental caries. Similarly, we learn from statistics that "the better the school the worse the teeth." On the other hand, during the war, when there was a notable scarcity of animal fats, milk, butter, and cream, what statistics we have indicate that there was a decrease in the prevalence of dental caries. There was, of course, a great reduction in the amount of sugar, sweets, etc., consumed, and the decrease in caries goes a considerable way to corroborate the "official" theory of the cause of the disease. I am not trying to indicate that meat, butter, and fats generally are harmful to the teeth; most dentists would agree that these foods are detergent in their effects, and had it not been for the shortage of these foods during the war the benefit of the restricted consumption of concentrated sugar (sweets, jam, etc.) would no doubt have been more conspicuous.

Consider the subject from another point of view. At the present day the temporary teeth of children are ravaged by caries, yet these teeth are calcified before the age when rickets is liable to supervene, and unlike the rachitic puppies under Professor Mellanby's care the temporary teeth of children, as a very general rule, take up a regular position in the jaws. Moreover, as a matter of fact, hypoplasia of the temporary teeth is most exceptional. In a recent investigation Mr. A. T. Pitts found only fifteen teeth showing hypoplasia in at least 4,000 cases. Yet caries of the temporary teeth is even more rampant than caries of the permanent teeth. Professor Mellanby may be disappointed in noting the conclusions which others draw from Professor Noel Paton's experiments on puppies, but his digression from rickets to dental caries does not appear likely to restore his fallen idol.—I am, etc.

London, W., May 28th.

J. SIM WALLACE.

ECLIPSE BLINDNESS.

Sir.—Dr. Lodge and Dr. Maxted describe serious cases of eclipse blindness, in which there was no visible change in the fundus oculi, although the vision was much impaired. I saw two less serious examples of this distressing result of exposure of the retina to the solar rays, and it may be of interest to send a few observations I made regarding them.

The general features of these cases were: (1) the short

time of exposure to the sun; (2) the presence of visible changes in the fundi; (3) a temporary central scotoma with diminished visual acuity; (4) complete recovery.

I will describe one of the cases more fully.

Miss J. T., aged 27, observed the eclipse on April 8th, 1921, for a few seconds only; she did not use any protective glass or other medium. On account of the photophobia she experienced, she at once desisted, but a little later noticed that vision was blurred. On the following day she attended the Birmingham and Midland Eye Hospital, complaining that since she had looked at the sun "things were blurred and she could not see the centres of things."

The visual acuity in each eye was 6/18, and the field of vision, normal with regard to its periphery, showed a small relative central scotoma. At each macula there was a yellow glistening line, which (magnified by the direct method of opthalmoecopy) was about an eighth of an inch in length. There was also slight pigmentation around the maculae. The patient was prescribed potassium iodide and ordered to wear No. 3 smoked goggles for a time.

On April 25th I examined the fundi again, but could find no sign of the changed appearance described above. On the occasion of each examination a mydriatic was used. On this day the vision was 6/6 in each eye. I saw the patient again on May 21st, and the visual acuity was unchanged and colour vision was normal. There was no central or paracentral scotoma, either relative or absolute, for white or coloured objects.

For permission to record the above case I am indebted to Mr. Fulford Eales.

With the suggestion that the public should be fully warned regarding the danger of observing eclipses without proper precautions I heartily agree. It seems remarkable that eclipse blindness occurs in such a small percentage of the interested observers.—I am, etc.,

H. W. ARCHER-HALL, D.O. Oxon.,
Assistant Surgeon, Birmingham and Midland
Eye Hospital.

May 23rd.

THE PREVENTION OF PUERPERAL INFECTION.

Sir.—Once again the general practitioner is being subjected to a more or less well-deserved criticism in respect of his midwifery. Last year a somewhat heated controversy took place in your columns along similar lines, more particularly concerning the use of forceps in relation to the relief of pain. Towards the close of the discussion one correspondent went so far as to state that the "agony" of childbirth was a myth, and indirectly suggested the abolition of chloroform anaesthesia in labour.

In so far as the general practitioner is concerned, the fault lies at the door of the teaching schools, or, to be more precise, at the door of those responsible for the college curriculum. It is not that facilities are limited. They are not; on the contrary, they abound, but unless the student is particularly interested in obstetrics, he will not take advantage of them. He is not compelled to do so, as he is in the case of medicine and surgery. For some obscure reason, obstetrics—the oldest of the three arts—has not been permitted to share the same scientific standing as medicine and surgery. The subject has been neglected. It forms a very hurried, insignificant part of the student's final year, consisting of, at the most, six months' theory, followed by the personal management of twelve cases of normal labour in the district of a maternity hospital. The application of forceps or the attempted treatment of an abnormal case is strictly prohibited. So long

with and a ticket is produced, and a ticket is produced, and have been undertaken, the authorities are presumably satisfied that that is all the experience required to practise obstetrics. The student is examined in theory, no clinical examination being considered necessary, and is then thrust upon a trusting public as a fully-qualified (*sic*) obstetrician.

In your issue of May 21st a correspondent makes the suggestion that midwifery should be a specialized subject, kept apart from general practice, and undertaken only by those to whom the work offers a special attraction. This would seem to be the ideal both to the practitioner who dislikes obstetrical work and to his patient. To those in general practice who specialize in obstetrics but dislike the remainder of their daily routine this suggestion, if materialized, would be a godsend; but, as your correspondent rightly says, the present scale of fees prohibits the occurrence of any such Utopia.—I am, etc.,

R. DOUGLAS HOWAT, L.R.C.P. and S.E.d.,
L.R.F.P.S. Glasg.

Hawick, May 23rd.

SIR,—Once again the subject of puerperal fever conveys heat to your correspondence columns, and I revel in it.

All are agreed on a few cold facts. Let me state them: The organisms responsible for puerperal fever are the *Streptococci pyogenes*, including those of erysipelas; the *Staphylococci aureus* and *albus*, also the organisms frequently associated with scarlet fever and diphtheria; pneumococci, gonococci, the organisms of typhoid and tetanus; and *Bacteria coli*. The last named has loomed large in recent years.

My figures, published in 1912, like those published by Matthews Duncan in 1876, prove that there is no connexion apparently between puerperal fever and erysipelas or scarlet fever. We may safely ignore pneumonia, typhoid and tetanus, and even gonorrhoea. We are left with the streptococci and staphylococci, and the *Bacteria coli*. If the *Bacteria coli* are responsible their source is not far to seek—namely, the mother. Personally I consider the case not proven. The streptococci and staphylococci may be traced to the mother, but again I am sceptical.

I claim to have been the first to suggest a reasonable explanation of the common source of those organisms—namely, where one would naturally look for them—that is to say, septic wounds. Now, how come they to reach the mother from septic wounds? Of course, if the mother is herself suffering from a septic wound, she infects herself; if not, they are conveyed to her by those attending her during parturition—that is, by the doctor or nurse, or both. Now, what is the common cause of septic wounds? I suggest industrial accidents are responsible for 95 per cent. To the question, How connect industrial wounds and puerperal fever? the answer is, by the individual who often treats both—that is, the medical practitioner.

I contend, without fear of contradiction, that this theory is the only one to explain the erratic and otherwise inexplicable incidence of puerperal fever.

To prove it I conceived the idea that if one classified districts according to the incidence of industrial accidents I would find the clue to explain the connexion between industrial accidents and puerperal sepsis. My book on the subject of which I still retain a few copies, and may be had for the cost of postage, proves my theory; I hold many letters from practitioners who agree with my conclusions, and I felt elated to fancy that Dr. W. Blair Bell referred to my statistics in his lecture published on May 14th.

I was not content, however, to rely on those figures only, and will give here a few others which further prove my contention. Notwithstanding the financial loss involved in my last attempt I propose again to publish a pamphlet on the subject, for like the man who found the goodly pearl I am prepared to sacrifice something to retain it.

There be few presumably who would claim any good to have come out of the great war, but even that calamity assists me in my fight for the truth. It occurred to me that there ought to be fewer accidents during the years 1915-18 (inclusive) than in normal times, so many men having to be withdrawn from industry, and if so that fact would be reflected in puerperal statistics. Unfortunately Government departments are unable to assist me in regard to accidents, but fortunately puerperal statistics for that period again prove my idea probable.

For the benefit of those still unfamiliar with my previous work—and I presume they are legion—let me briefly summarize a few chief figures and compare them with the succeeding ten years, including the war years. I have confined my present statistics to the administrative county of Lancaster.

Puerperal Rate per 1,000 Births in Classified Districts.

Lancashire Districts Classified.	(1) 1900-09.	(2) 1910-19.	(3) 1915-18 (War Years).
Mining districts ...	4.56	3.23	2.62
Manufacturing ...	3.2	2.80	2.35
Mixed ...	2.5	2.57	2.33
Residential ...	2.19	1.9	1.9
Rural ...	2.10	2.69	3.39

Note (1) the varying incidence and the decreasing rates from above downwards in columns 1 and 2; (2) the lower rate in column 3 for the upper three districts; (3) the fixed rate in column 3 for residential districts; (4) the increased rate in column 3 for rural districts; and observe that the three upper districts are those likely to be affected by withdrawal of industrial workers, and hence to experience a decrease of industrial accidents.

Further, is it a coincidence that I can prove the attack rate per 1,000 births was 2.35 in the period 1915-18, and 3.08 in the previous five years? Or, again, that a four months' strike in the cotton trade in 1910 coincided with a puerperal rate for that year lower than for any year since the Midwives Act—a fact which induced undue optimism in the mind of the M.O.H. for Lancashire, rudely shattered by the statistics of the succeeding four years.

Can any of your readers suggest any other explanation of these facts?

I may be puffed up by statistics, but am prepared to be let down by reason. I must refrain from answering Dr. C. M. Stevenson at length, and also from wearying your readers by statistics showing the relative responsibility of doctors and midwives.—I am, etc.,

Heywood, Lancs. May 21st.

GEORGE GEDDES.

SIR,—Dr. Vaughan Pendred speaks of an experience of twenty-seven years. Alas! I can quote a longer one. Time has taught me the value of gloves and a sterile jacket. The former are more readily washed in soap and water or soaked in perchloride if by chance the hands have touched any unclean thing of the patient or surroundings. Mercury biniodide roughens the hands and in time renders them difficult to maintain clean; in the winter antiseptics are often self-destroying.

I would say soap and water, boiled rubber gloves and a sterile jacket, the avoidance of lubricants and "meddlesome midwifery," including the odd examinations by maternity nurses, will not introduce sepsis, and if not introduced it will not want dealing with by strong antiseptics.

Much of my work is major and minor surgery; I carry out in midwifery practice the technique so far as possible of the operating table.

Antiseptics are a snare to the careless; the use of soap and water and sterile rubber gloves are a definite double event which can only do good if merely by shutting off our finger nails.

In the individual case the causation of puerperal infection may be within or without the patient.—I am, etc.,

Dorchester, May 29th.

W. B. COSENS.

REFRACTION WORK IN CHILDREN.

SIR,—Any Education Committee which expects its medical officer to complete six cases in an hour must also expect to have the work scamped and unsatisfactory results exhibited; on the other hand, somewhat more than three cases done with care and accuracy must be expected at the hands of every refractionist. I have been engaged in this work for a period extending over seventeen years and comprising such a number of cases as has passed into thousands, and am able to say that nine cases in a session of two hours is an average and that subjective methods must be combined with retinoscopy—in fact, where any reliance can be placed upon the information obtained from the subject, the subject must have the last word. In many clinics where too much work is demanded, and only objective methods are practised, a large number of the children in various ways express discomfort; especially is this so among hyperopes where over-correction almost appears to be the rule; such children return again and again for re-examination, so that while the number of attendances is a maximum the number of cases satisfactorily disposed of is a minimum; or many such children seek the assistance of opticians who, founding their subjective test upon a measurement of the glasses in question, are often, very often, able to remove that discomfort which ought never to have existed. In the case of very young children and those of defective mental capacity or interpretation, only objective methods can be practised, but surely these should be the exception and not the rule.—I am, etc.,

London, W., May 30th.

H. G. CRITCHLEY, M.D., D.P.H.

DEFECTS IN TUBERCULOSIS ADMINISTRATION.

SIR.—Your leading article (BRITISH MEDICAL JOURNAL, May 7th, 1921, p. 678) on the new tuberculosis regulations brings into prominence one of the great defects in the organization of the public health service—namely, the haphazard division of work between the county medical officer of health and the medical officer of health for a district within the county. Assuming for the moment that both kinds of health officers are necessary, surely the work should be so apportioned that each has a definite and appropriate share and the natural division is local work for the local man, provincial work for the provincial man.

Let us see how far this applies to the tuberculosis scheme. In the first instance, the general practitioner is required to notify every fresh case of tuberculosis coming to his knowledge to the medical officer of health for the district where the patient resides. It is the duty of that medical officer to see that notification is duly carried out, to keep trace of the patient as he moves within or out of the district, or enters or leaves an institution, or dies; but, apart from attending to any insanitary conditions which may affect the patient or the spread of infection, the local medical officer of health has no further concern with the case, nor is he in a position to render any effective service. The formal information which he has collected is passed on in a weekly return to the county medical officer of health, who in turn directs the work of the tuberculosis officer (and nurse) under whose supervision the patient remains. There is, unfortunately, no reciprocity between the tuberculosis officer who looks after the person of the patient and the local medical officer of health who looks after his surroundings.

Clearly all local work comprised in the term "domiliary treatment" should be done under the eye of the local medical officer of health, and the sanatorium treatment, which rests on a larger basis, would be properly left entirely in the hands of the county medical officer, while the position of the tuberculosis officer between the two might be roughly compared to that of a liaison officer. One can hardly imagine a more inconvenient and uneconomical arrangement than that which at present exists in regard to bringing tuberculosis officer and patient into contact, for the earliest the former can hear of a new case is through the local medical officer of health and the county medical officer of health, after a delay of any time up to a week! On the other hand, neither the tuberculosis officer nor the county medical officer can deal with the patient's environment—for example, overcrowding, defective sanitation, etc., except through the local medical officer of health. For all local matters at least no great harm would result if the county medical officer of health were cut out of the circuit, and the way by which this could be effected was clearly indicated in the Regulations of 1912, referred to in your leader.

The inconsistency, so apparent in this rough and ready division of work, leads to a great deal of confusion and, naturally, at times, to no small amount of friction between county and district medical officers of health. The remedy would not be difficult to find if those who have actual experience of the work and its peculiar problems were consulted, while, by a revision and consolidation of the numerous scrappy Orders and Regulations now in existence, the whole matter could be quickly settled.—I am, etc.,

May 16th.

MIXTURE.

THE first of a series of three new buildings for the University of Manitoba is nearly completed, and will provide accommodation for the departments of biochemistry, bacteriology, and physiology, with provision for laboratories, lecture rooms, museums, and departmental libraries.

THE records of the New York Health Department show that for the first fourteen weeks of 1921 the infant mortality rate was 80 per 1,000 children born, as against 112 for the corresponding period of last year. In commenting upon this reduction, which represents a saving of 1,132 infant lives, the Health Department suggests the possibility that the mild winter, which resulted in better ventilation of premises and in children being out of doors a greater part of the time, may have been a factor, and also that better food, better clothing, and the more general dissemination of information in regard to hygiene may be responsible.

Obituary.

RICHARD EUGENE HARCOURT, M.D., F.R.C.S.,

Ophthalmic Surgeon, Bootle Borough Hospital.

DR. HARCOURT, who died at his residence in Oakfield Park, Liverpool, on May 19th, was born in 1858 at New Jersey, U.S.A. His father was a native of County Down, Ireland, and his mother an American lady of Dutch extraction. Harcourt spent his school life partly at Newry and partly at the Liverpool Institute. He received his medical education at Queen's College, Belfast, and graduated in 1887. He remained a keen student all his life, as is shown by the post-graduate degrees which he acquired—the M.D. and B.A.O. of the Royal University of Ireland in 1893, the M.D., M.S. Uruguay in 1893, and finally the F.R.C.S. England in 1907. After a period of service under Mr. (now Sir) Robert Jones at the Royal Southern Hospital and at one of the Manchester Ship Canal hospitals, Harcourt went to Buenos Aires, where he practised for ten years and was medical officer to the Buenos Aires port works and to the Government police at Las Conchillas. He returned to England in 1893, and after a short spell of practice at Warrington settled down in Wavertree, Liverpool. He retired from general practice about ten years ago and devoted himself to ophthalmology, being appointed pathologist to the Liverpool Eye and Ear Infirmary; later he became also assistant surgeon to this hospital and ophthalmic surgeon to the Bootle Borough Hospital and assistant ophthalmic surgeon to the St. Helen's Hospital. His excellent pathological work secured for him a lectureship in ophthalmic pathology at the University of Liverpool. During the war he gave invaluable assistance to the depleted staff of the St. Paul's Eye Hospital. To all this work and to an increasing private ophthalmic practice Dr. Harcourt added a large amount of ophthalmic school work for the Bootle and Liverpool education authorities, industrial schools, and for the Roman Catholic school committees.

There can be but little doubt that overwork was one of the contributory causes of his last illness. He had suffered from dysentery while abroad, and recurrences of this trouble were not infrequent. About a year ago he became anaemic, and this affection turned out to be of the "pernicious" type; transfusion (thrice repeated) and all the remedies that the physician and bacteriologist could devise were applied without avail. During a temporary improvement in his health last autumn Harcourt returned to full work, to which he clung pathetically, only to be forced to relinquish reluctantly duty after duty.

With the exception of reading and his social and family duties Harcourt's relaxation consisted simply of change of work. Though he began to specialize as an ophthalmic surgeon late in life, he was a good operator, and his wide reading and full knowledge of general surgery and pathology made him a thoroughly sound practitioner and a successful and inspiring teacher. Dr. Harcourt was a member of the Liverpool Medical Institution, where he frequently showed patients and pathological specimens, was one of the original members of the North of England Ophthalmological Society, and a member of the British Medical Association. He was an ardent Freemason and an active supporter of the Wesleyan Church.

As a man and colleague Harcourt was genial, kind and loyal, ever young and progressive; if he had a fault it was that he spoilt his colleagues by his good-natured readiness to help them when they were lazy or tired, ill, or overworked. Dr. Harcourt is survived by his wife, two sons, and three daughters.

DR. ARTHUR SNEYD TAYLOR, of Surbiton, who died on April 7th after two days' illness, was born in 1859 and educated at Merchant Taylors' School, where he won a mathematical scholarship and proceeded to Pembroke College, Cambridge. He graduated B.A. in the mathematical tripos in 1882. He then entered Guy's Hospital and took the diploma of M.R.C.S. in 1886 and the Fellowship two years later, and graduated M.B., B.Ch. Camb. in 1887 and M.D. in 1893. He was surgeon to the Surbiton Cottage Hospital. Dr. Taylor was a noted Rugby footballer. He represented Cambridge, Guy's, and Blackheath in the eighties; played for the South against the North and for England against Wales in 1882. He played again

for England in 1883 and in 1885-86. During the war he was temporary Captain, R.A.M.C.(V.), and took an active part in the work of the Kingston-Surbiton District Red Cross Hospital and of the Oakenshaw War Hospital. On his retirement in March, 1920, he was granted the honorary rank of captain. He was a member of the Kingston Division of the British Medical Association.

Universities and Colleges.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—*SC. H. Medal, †Florence
R. Clnlow, J.H. A. Har *A. G. Maitland
Jones, IV. E. Negus, E. Alcock, G. C.
Agarwal, W. M. Anthony, J. R. Banks, Mary R. Barkas, F. M.
Barnes, H. E. Beasley, Ursula P. Blackwell, H. J. Blampied,
J. Brodie, P. C. P. Cloake, E. V. Corry, Elsie E. Cowperthwaite,

UNIVERSITY OF BRISTOL.

THE University Council at its meeting on May 27th received the resignation of the Vice-Chancellor, Sir Isambard Owen, M.D., who, having reached the age of 70, is due to retire under the operation of the Treasury new rules with regard to superannuation. The resignation takes effect at the end of the present session. Sir Isambard Owen, who went to Bristol in 1909 in succession to Professor Lloyd Morgan, is responsible for practically the whole of the organization of the University.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—*E. D. Fenwick, *H. L. Sheehan, *J. Solomonoff.
MEDICINE.—†E. E. Edwards, *M. A. K. El. Hennawy, *†E. D. Fenwick, *O. E. Finch, *A. Mishriky, *H. L. Sheehan.
FORENSIC MEDICINE.—F. E. Edwards, M. A. K. El. Hennawy, E. D. Fenwick, O. E. Finch, H. L. Sheehan, M. Tcherny, R. E. Williams.
MIDWIFERY.—M. A. K. El. Hennawy, E. D. Fenwick, M. Fox, A. Senn, H. L. Sheehan.

* Section I. † Section II.

The diploma of the Society has been granted to Messrs. E. D. Fenwick and J. Solomonoff.

The Services.

DEATHS IN THE SERVICES.

SURGEON-MAJOR HENRY COOKSON, Bengal Medical Service (retired), died at Cheltenham on April 22nd, aged 88. He was born on February 10th, 1833, the son of Mr. Thomas Henry Cookson of Boston, and was educated at Edinburgh University, Leeds, and St. Thomas's Hospital. He took the M.R.C.S. in 1856, and entered the Royal Navy as assistant surgeon in the same year, but resigned with less than three years' service. In 1859 he took the L.R.C.P. (Edin.), and entered the I.M.S. on January 20th, 1860, attaining the rank of surgeon-major on July 1st, 1873, and retiring on May 20th, 1880. He also took the F.R.C.S. (Eng.) in 1870, and the D.P.H., after retirement, in 1882. He served on the North-West Frontier of India in the Jowaki campaign of 1877-78, when he was mentioned in despatches, in G.G.O. No. 738 of 1878, and received the frontier medal; and in the second Afghan war of 1878-79, when he took part in the capture of Ali Musjid, was again mentioned in despatches, in G.O.C.C. of October 14th, 1879, and received the medal with a clasp.

Fleet Surgeon Anthony Kidd, R.N. (retired), died on April 24th at Bath. He was educated at the Ledwich School, Dublin, and took the L.R.C.S.I. in 1879 and the L.K.Q.C.P. in 1880; he entered the navy and attained the rank of fleet surgeon on February 26th, 1897. Before his retirement he was serving as principal medical officer at Pembroke Dock, and afterwards filled the post of surgeon and agent at Falmouth; subsequently he practised at Bath.

Lieut.-General Sir Launcelotte Gubbins, K.C.B., formerly Director-General A.M.S., has been reappointed a Special Commissioner of the Royal Hospital, Chelsea.

Medical News.

THE following committee has been appointed by the Minister of Pensions to inquire into the management by the Ministry of Pensions and the Joint Disablement Committee for the South-West of Scotland, of Bellahouston Hospital, and especially the organization of the out-patient department: The Right Hon. Lord Scott Dickson, P.C., K.C. (chairman), Sir Donald MacAlister, K.C.B., president of the General Medical Council, Mr. W. Grieve, a disabled soldier, and Colonel Sir Arthur L. A. Webb, K.B.E., C.B., Director-General of Medical Services, Ministry of Pensions.

THE annual dinner of the Indian Medical Service will be held at the Trocadero on Wednesday, June 15th, Major-General Sir R. Havelock Charles, G.C.V.O., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 63, Addison Road, Kensington, W.14.

THE Cavendish lecture, followed by the annual conversation of the West London Medico-Chirurgical Society, will be delivered at the Kensington Town Hall by the Right Hon. Christopher Addison, M.D., M.P., on Friday, June 17th, at 8.15 p.m. The subject of the lecture will be "The part of the State in the prevention of disease." A reception will be held at 7.45 p.m. Members requiring tickets for guests are asked to communicate as early as possible with the Hon. Secretary, Dr. D. G. Rice-Oxley, M.C., 22, Victoria Road, W.8.

COMMEMORATION DAY took place on May 27th at Livingstone College, London, E., when many friends of foreign missions were present at a gathering presided over by Sir George Makins, who said that it was necessary that the missionary, to fulfil his aim, should have, in addition to his theological training, some knowledge of medical things. He remarked on the great value in the mission field of the partial medical training which was obtained at Livingstone College. The value of this training was further emphasized by the personal experiences related by Dr. G. E. King, of the China Inland Mission, and the Rev. L. Taylor of the Moravian Mission, Nicaragua.

A SESSIONAL meeting of the Royal Sanitary Institute will be held on June 9th and 10th, in the Guildhall, Gloucester, jointly with the West of England Branch of the Society of Medical Officers of Health. On June 9th at 10 a.m. a discussion on "Public health development in Gloucestershire" will be opened by Dr. J. Middleton Martin, County M.O.H. Gloucestershire. On June 10th, at 10 a.m., there will be a discussion on "The collection and disposal of house refuse." The chair will be taken by Professor H. R. Kenwood.

THE annual general meeting of the Governors of Epsom College will be held at the offices, 49, Bedford Square, W.C.1, on Friday, June 24th, at 4 p.m.

ON May 14th the 125th anniversary of the first vaccination performed by Edward Jenner was celebrated in the hall of Leyden University by the Dutch Society for the History of Medicine and Natural Philosophy. Addresses were given by Professor E. C. Van Leersum and Mr. C. J. S. Thompson, Curator of the Wellcome Museum.

A QUESTION was recently addressed in the House of Commons by Mr. Robert Young, M.P., to the President of the Board of Education on the subject of whether the earlier hours of attendance and the consequently prolonged day due to the operation of the Daylight Saving Act had had any injurious effect on the health of young children. A circular has been sent to local education authorities by the medical department of the Board of Education asking than an endeavour should be made to ascertain through school medical officers and teachers the effect during the current year of the Summer Time Act on the health of school children, and on their proper attention to school work.

A MEDICAL congress will be held at Helsingfors from June 30th to July 2nd. The principal subject to be discussed is the treatment of syphilis—(a) of the central nervous system, and (b) of the thoracic and abdominal viscera.

THE next course of international post-graduate lectures in Vienna will begin on June 6th. Full particulars can be obtained from the Dean of the Medical Faculty at the University, Franzensring, Vienna 1. The course will consist of lectures, by professors of the Medical Faculty, on recent advances in surgery, orthopaedics, gynaecology, and pediatrics.

THE annual meeting of the British Science Guild will be held at the Goldsmiths' Hall, Foster Lane, London, on Wednesday next, June 8th, at 3 p.m., when Dean Inge will speak on "The road to ruin and the way out," and Sir Richard Redmayne will give an address on the importance of research in promoting the development of mineral industries.

THE annual dinner of the Harvelan Society of London will be held at the Café Royal, Regent Street, on Wednesday, June 22nd, at 7.30 p.m.

ON the occasion of the departure of Dr. D. A. Powell from the district to become superintendent of the Welsh Sanatorium at Denbigh, the medical practitioners of Anglesey entertained him to a very successful dinner, held on May 13th, as a mark of esteem and of the cordial relations that had existed between Dr. Powell, as tuberculosis physician to the Welsh National Memorial, and the practitioners of the district.

THE second annual general meeting of the Society for the Prevention of Venereal Disease will be held at 5.30 p.m. on Monday, June 6th, at the Barnes Hall, 1, Wimpole Street (kindly lent by the Royal Society of Medicine).

As already announced, the annual provincial meeting of the Society of Medical Officers of Health will be held on Saturday, June 11th. Owing to a printer's error in the notice sent to members, we are asked again to draw attention to the date.

THE June number of the New York Medical Review of Reviews will be a special radium number dedicated to Madame Curie, and will consist exclusively of articles on radium and its uses by the most prominent radiologists in the United States and Canada.

THE fifty-second annual meeting of the Canadian Medical Association is announced to take place at Halifax, Nova Scotia, from July 5th to 8th, under the presidency of Dr. Murdoch Chisholm.

As a step in the reconstruction plans of Yale University the subjects of pharmacology and experimental medicine have been combined into a university department with the title of the Department of Pharmacology and Toxicology. Special attention is to be devoted to the training of future investigators and teachers, and to the chemistry and physiology of the action of drugs and poisons.

ACCORDING to the *Journal of the American Medical Association*, an unusual situation has been brought about in the Johns Hopkins Medical School and the Johns Hopkins Hospital by the resignation of Dr. William S. Thayer, professor of medicine in the medical school and physician-in-chief of the hospital, who was chief medical advisor of the American Expeditionary Force during the war. The seventy physicians connected with the department of clinical medicine have offered their resignations in response to a circular letter sent out by the medical board of the hospital. This letter explained that none of the members of the department would be reappointed prior to the selection of the successor to Dr. Thayer. This course was taken in order that the new professor of medicine and physician-in-chief of the hospital might have a free hand in reorganizing his department and carrying out the policy involved in the idea of a full-time professorship.

IN addition to the post-graduate courses in medicine at the Hôtel-Dieu already noted in the JOURNAL, a number of other vacation courses will be given in Paris during this summer and autumn. At the Hôtel-Dieu, from July 1st to 31st, there will be a course on diseases of the digestive tract and the biliary ducts, by Professor Hartmann and others, and at the Salpêtrière Hospital, from June 27th to July 11th, a post-graduate course on surgical technique, including practical work, by Professor Gosset, assisted by Dr. G. Loewy and others; this latter course will be conducted in English, and will be limited to twenty medical men. At the Hôpital de la Pitié, from June 20th to July 10th, a course on diseases of the heart, blood-vessels, and blood will be given by Professor Vaquez and others, and at the Hôpital des Enfants Malades, from August 17th to September 3rd, a course on diseases of children has been arranged by Professor Nobécourt. At the Broca Hospital, from September 19th to October 1st, a course on gynaecology will be given by Professor J. L. Faure and his colleagues. In the histological laboratory of the faculty of medicine there will be during the month of October a course on histology, by Professor Prenant, and in the

October 5th to 30th, a course

Letulle. At the Hôpital Laennec and other three hospitals in conjunction, from July 4th to 17th, a course on tuberculosis will be carried on by Professors Léon Bernard, Bezançon, Anguste Broca, Letulle, and Renon, and in the laboratory of the faculty,

from July 1st to 12th, a course on parasitology will be given by Professor Brumpt. At the School of Child Welfare, 64, Rue Desnouettes, Paris (XV), from October 3rd to 13th, a series of lectures on child welfare, with visits to the Parisian municipal centres, has been arranged by Professor A. Pinard and others; further information on this course may be obtained, before September 25th, from M. Weisweiler, administrator of the school. In regard to all the other courses particulars will be given by the Secretary of the Faculty of Medicine of Paris, to whom application should be made, before June 15th, in the case of courses before the month of August, and before July 15th, in the later courses. The fees range from 50 francs, for the child welfare course, to 80 francs for the courses on histology and pathology, and 150 francs for the clinical courses. Information regarding such matters as travel and accommodation will be given by the Association for the Development of Medical Relations, at the Faculty of Medicine of Paris.

THE University College Hospital Ladies' Association, founded some twenty years ago to provide clothes for patients in the wards and to help patients when discharged, has now some eight hundred members and ten local branches; it maintains two beds and its junior branch a cot. Its latest work has been the establishment of an infant welfare department. The hospital is in financial difficulties, and the Ladies' Association will hold a sale on June 8th at Someries House, Regent's Park, the residence of Major Harold and Lady Zia Wernher. The sale will be opened by Princess Helena Victoria at 11.30 a.m.

SIR KENNETH W. GOADBY, K.B.E., M.R.C.S., lecturer on bacteriology at the National Dental Hospital, has been appointed to represent medical science on the Advisory Committee for the Metalliferous Mining Industry.

MESSRS. A. W. GAMAGE, of Holborn, E.C.1, have issued a new catalogue containing particulars, with prices, of a very large number of motor accessories.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

Communications who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ARTISTS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology, Westrand, London;

2. FINANCIAL MANAGER
Advertisements, telephone,
2630, Gerrard.

Mediacera, Westrand, London;

address of the Irish Office of the

16, South Frederick Street, Dublin

telephone, 4737, Dublin), and of

the Scottish Office, 6, Rutland Square, Edinburgh (telegrams:

Associate Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

DIACETIC ACID TESTS.

"F. B." (*Orange Free State*) writes: I should be glad to know of the stains of a baby's normal urine to which diacetic acid has been added does not give the purple reaction with ferric chloride solution as one would expect.

"Diacetic acid (and acetone), being volatile substances, cannot be detected by any test in a stain on a napkin. The only way would be to test the fresh expressed urine with the nitro-prusside test (this is best done as a ring test), which shows both acetone and diacetic acid. The blood can also be examined for acetone, and the carbon dioxide content of the alveolar air determined to show acidosis.

INCOME TAX.

"T. G." bought out his senior partner on January 1st, 1920. He asks whether he can deduct as an expense in calculating his income tax return that portion of the gross receipts which

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

631. The Starvation Treatment of Diabetes

MOTZFELDT (*Norsk. Mag. for Læger og Lægerstuderende*, April, 1921) has compared the results achieved at his hospital in the treatment of diabetes by fasting, as practised by Allen and other Americans, with the results of less stringent dietetic measures. His verdict is emphatically in favour of the starvation treatment. Under the old régime 54 cases were treated between 1912 and 1917, the average age being 44 years. Under the starvation régime he treated 77 cases between 1917 and 1920, the average age being 36 years, and the proportion of severe cases comparatively high. Yet the results were far better in the latter period. As a table shows, only 44 per cent of the first class were discharged from hospital without glycosuria and ketonuria, whereas this result was achieved in 79 per cent of the latter class. In this class only 5 per cent died in diabetic coma, as compared with 13 per cent in the earlier period. As the author's illustrative cases show, the starvation treatment can effect recoveries in cases of juvenile diabetes which a few years ago would have inevitably been regarded as doomed to an early death. While children and young adults tolerate the fasting diet well, great care should be exercised in cutting down the diet of elderly patients and of fat persons, who, by rapid oxidation of their own fat, are apt to suffer from ketonuria.

632. Can the Diabetic be Allowed to Lose Flesh?

RATHERY (*Bull. Soc. de Théol.*, March 9th, 1921) answers this question as follows. Loss of flesh in diabetes may be allowed provided the patient is fat and a large eater and the loss of flesh is confined within certain limits. He may also be allowed to lose flesh temporarily as the result of a relative or absolute starvation regimen. With these exceptions, a diabetic patient should not be allowed to grow thin. Loss of flesh due to dietetic errors can easily be corrected. Lastly, the loss of flesh may be pathological, indicating either a more or less latent tuberculosis or some serious disturbance in the carbohydrate metabolism.

633. Pseudo-leukaemic Splenic Anaemia in Infants

MANCINI (*Riv. Osped.*, January 15th, 1921) records three cases (two of them twins) of this disease, in children aged 2 years and 18 months respectively. In the first case there was evidence of syphilis, rickets, and dyspepsia—in the twins rickets was the only predisposing condition present. These patients have many of the symptoms of pernicious anaemia, but the blood differs by the presence of leucocytes (and the greater number of leucocytes the worse the patient) and in the low globulin index, without any marked diminution in the red corpuscles. Although the number of red corpuscles is usually low (1 to 2 million) in this disease, there is a high percentage of nucleated red corpuscles, the leucocytes average 20,000 and neutrophils predominate. The state of the blood may remain unchanged for months or years, and the prognosis does not depend on the state of the blood. Some children improve remarkably under aiseic or change of surroundings, but the majority die of some intercurrent affection. Pseudo leukaemic anaemia is distinguished from true leukaemia by the scanty presence or absence of eosinophils and mast cells, and the liver increases relatively less than the spleen. The disease is never seen after the third year, symptoms may appear at six months, both sexes are equally affected, there is no evidence of heredity but a family tendency may be seen—for example, brothers, especially twins, may develop it. Usually there is marked rickets. The spleen reaches the umbilicus, is hard and painless, and easily movable, the lymphatic glands are, as a rule, not enlarged to any extent.

634. Pleurisy with Effusion on the "Sound" Side in Artificial Pneumothorax.

DE REYNIER and ROSSÉL (*R. v. med. Suisse rom.*, March, 1921) state that though effusion on the affected side is excessively common in the course of treatment by artificial pneumothorax, effusion on the sound side is very rare, only two cases having hitherto been published by Als and Süssdorf respectively. The writers record two more cases

of this kind in which, like the two cases mentioned, recovery took place and the treatment by artificial pneumothorax could be continued. The writers come to the following conclusions: (1) Effusion on the "sound" side in artificial pneumothorax is a complication independent of the treatment and must be regarded as an ordinary infective pleurisy, probably of tuberculous origin. (2) The appearance of an effusion on the opposite side to the pneumothorax is a grave but not necessarily fatal complication, in spite of the considerable diminution of the respiratory area. (3) The evolution of these pleurisy is identical with that of ordinary pleurisy. In the writers' two cases the absorption of the effusion was complete in three months, and in neither case did the subsequent lung tissue suffer. (4) Treatment, as in ordinary pleurisy, must be symptomatic at first. If the dyspnoea is very intense, the effusion must be evacuated, and owing to the other lung being out of action operation will be required rather than in ordinary pleurisy with effusion. If there is at the same time hydropneumothorax on the side treated by insufflation, this side should be evacuated first, and the fluid replaced by nitrogen. But if there is only a very small effusion, no treatment is required, and the insufflation should only be resumed when the acute stage of the pleurisy on the opposite side has subsided.

635. The Duration of Artificial Pneumothorax.

JACQUEROD (*Rev. med. Suisse rom.*, March, 1921) states that in a large number of cases the question of how long an artificial pneumothorax should be maintained is decided by itself, the lung, as the result of a pleural effusion, resuming its place in the thorax, or the thorax becoming filled up by fibrous deposit without it being possible to prevent this occurrence. Among 22 cases of this kind Jacquered saw the tuberculous process assume a more or less rapid course after absorption of the effusion in 12, in 5 its course was slightly delayed, in 3 there was considerable improvement, which was maintained for three or four years, and in 2 apparent recovery took place. But when no effusion occurs, or when the pleural cavity remains free after absorption of the effusion, Jacquered considers it advisable to keep up the artificial pneumothorax indefinitely to prevent relapses, and sometimes throughout the patient's lifetime.

636. Artificial Pneumothorax in Bilateral Tuberculosis

CAESINUS (*Il Politecnico*, Ser. Prat., April 25th, 1921) has performed artificial pneumothorax in 52 cases of pulmonary tuberculosis, which he classifies into the three following groups: (1) Cases of unilateral tuberculosis with lesions of varying degree, (2) cases of bilateral tuberculosis with slight and early lesions on the opposite side to the pneumothorax, (3) cases of bilateral tuberculosis with extensive but not very far advanced lesions on the opposite side to the pneumothorax. In 24 cases the pneumothorax had to be discontinued—in 12 on account of pleural adhesions, in 5 for a large pleural effusion; in 5 for anaemia, in one for cardio-gastric disturbance, and in one for haemoptysis. In 11 cases of unilateral tuberculosis the results were so good that a complete cure could be expected, and in 17 cases of bilateral disease, so far from there being any sign of aggravation, there was evidence of improvements, in patients both of the second and third groups. Caesinus, therefore, concludes that artificial pneumothorax is of undoubted value in bilateral pulmonary tuberculosis.

637. Singer's Thirst Cure for Bronchiectasis

VOGELIUS (*Hospitalstidende*, March 23rd, 1921) and TOLDEPLUND (*Ibid.*, April 6th, 1921) record cases in which Singer's system of cutting down the fluid intake to a minimum proved remarkably beneficial in relieving the symptoms of bronchiectasis. Vogelius's patient was a man, aged 63, who suffered from bronchiectasis, foetid bronchitis, and anaemia. There were no crystals, spurs, nor tubercle bacilli in the sputum, which amounted to 200 to 500 c.cm. in the twenty-four hours. After three weeks' futile treatment in hospital with expectorants, codene, and Quincke's postural treatment, his fluid intake was reduced, and after three weeks his sputum amounted only to 75 c.cm. Within two months of this treatment the sputum was reduced to only a few pieces. He gained 10 kilos in weight, and when he was discharged he had

ceased to expectorate and felt perfectly well. Tolderlund's patient was a woman, aged 38, whose foetid mucopurulent sputum had persisted for a long time in spite of medicinal treatment. She was subject to bouts of fever, and was dyspnoeic, thin, and pale. After a month's treatment in hospital under Singer's régime the sputum was reduced from 300-400 c.cm. to 50-60 c.cm. Coincident with this reduction of the sputum there was a marked change for the better in her general condition, and she gained 6 kilos. During the following years she found it necessary to repeat this cure in her home three or four times a year whenever the sputum became profuse and foetid. When last seen she was fit for work, and her general condition was comparatively good.

648. Non-tuberculous Inflammation of the Bronchial Glands.

GÄHWYLER (*Schweiz. med. Woch.*, April 7th, 1921) criticizes the fashionable tendency to diagnose tuberculosis of the bronchial lymphatic glands on the strength of x-ray findings and certain physical chest signs. He records in detail seven cases (five children and two adults) observed during one winter in Arosa. The clinical picture conformed closely with that of early tuberculosis; the patients were easily tired and complained of pain between the scapulae and in the sternum, as well as of dyspepsia. In some cases the temperature was subfebrile and in others there was a troublesome cough with signs of chronic bronchial catarrh. Paravertebral areas of dullness, harsh inspiration, pectoriloquy, and other signs

and shadows seemed to have at first sight little doubt as to the diagnosis of tuberculosis of the bronchial glands. But the sputum never contained tubercle bacilli, and cutaneous, intracutaneous, and subcutaneous tuberculin tests were invariably negative, even when such a heroic dose as 10 mg. of old tuberculin was given. The author insists that the diagnosis of non-tuberculous inflammation of the bronchial glands stands or falls by the tuberculin test, and as this is often positive in the absence of tuberculosis of the bronchial glands, it follows that there must be many more cases of non-tuberculous inflammation of the bronchial glands than can be demonstrated as such. The whole tenor of the author's paper is protestant against committing the diagnosis of intrathoracic lesions to the unsupported evidence of the radiographer.

649. Occupational Dermatitis in Dentists.

LANE (*Arch. of Derm. and Syph.*, March, 1921) records three cases of dermatitis in dentists due to procain—a local anaesthetic closely allied to novocain. The eruption was circinate and erythematous, with a tendency to the development of fissures affecting the fingers and palms. Where the solution had inadvertently touched the face a pronounced reaction was seen. Skin tests with a solution of procain showed a marked individual susceptibility in each case. The treatment is obviously the wearing of rubber gloves in susceptible cases.

SURGERY.

650. Indications for Operation in Gastric Ulcer.

ACCORDING to SCHÖNFELD (*Nederl. Tijdschr. v. Geneesk.*, April 9th, 1921) the indications for surgical interference in gastric ulcer are as follows: (1) In obstruction of the gastric contents as the result of pyloric stenosis or hour-glass contraction, as soon as persistent symptoms arise which prove refractory to any other kind of treatment. (2) In perigastritis with adhesion of the stomach to neighbouring organs operation is the only method of treatment. The diagnosis of adhesions has been facilitated in recent years by radiographic methods with insufflation of oxygen or sterile air into the abdominal cavity. (3) Persistent hyperacidity, especially when associated with dilatation of the stomach and weakness of the gastric wall. Gastro-enterostomy, he states, is the operation of choice in these cases. Section of the branches of the vagus in the neighbourhood of the cardia has recently been recommended, as the hypersecretion and motor disturbances have been attributed to vagotonia.

651. Implantation of the Ureter into the Bowel.

ACCORDING to COFFEY (*Surg., Gynec., and Obstet.*, May, 1921) the essential mechanical principle necessary for successful implantation of the ureter into the intestine is that before entering the lumen of the intestine the ureter shall be made to run for some distance immediately under the loose mucous membrane. In animal experiments the

author noticed that direct implantation of the common bile duct or of the urinary duct into the intestine was followed by very considerable dilatation of the duct concerned, and in the case of the ureter by destruction of the kidney. The dilatation of the duct is to be ascribed to the static intra-intestinal pressure; consideration of the course taken in natural circumstances by the bile duct in its passage through the wall of the duodenum led to the surmise (afterwards verified experimentally) that by giving the implanted duct a submucous course immediately before its new termination, the intra-intestinal pressure would be brought to bear on the near side of the implantation opening and retrograde dilatation of the duct would thus be prevented. Using his modifications of Coffey's technique, Mayo had 22 successful results in 26 operations. Coffey records four cases in which six ureters were implanted with subsequent good function.

652. Statistics of Gastric and Duodenal Ulcer.

EISELSBERG (*Wien. klin. Woch.*, March 10th, 1921) gives the following statistics of the operations for gastric and duodenal ulcer performed in his clinic since 1918. (a) Operations for uncomplicated cases: Gastro-enterostomy, 42 cases with 1 death; exclusion of the pylorus, 9 cases with 1 death; resection and exclusion of pylorus, 28 cases with 1 death; transverse gastric resection, 38 cases with 2 deaths; Billroth's first operation, 79 cases with 2 deaths; Billroth's second operation, 164 cases with 9 deaths—a total of 301 resections with 13 deaths, or a mortality of 4.3 per cent. (b) Operations for complicated cases: 11 cases of gastric perforation with 4 deaths; 5 cases of acute haemorrhage with 3 deaths; 12 cases of jejunal peptic ulcer with 3 deaths; 7 cases of secondary operation owing to relapse or failure of first operation, with 2 deaths.

653. Gastric Syphilis.

ACCORDING to FOWLER (*Surg., Gynec. and Obstet.*, May, 1921), who reports a case of benign, non-specific ulcer occurring in the stomach of a female syphilitic subject aged 26, organic syphilis of the stomach is less infrequent than was formerly supposed. The gross lesions are diffuse infiltration, or gummata progressing to ulceration. At operation, syphilitic gastric ulcers are found to be multiple and ragged, occurring usually in the region of the cardia, pylorus, or lesser curvature; often they are accompanied by perigastric adhesions and by thickening and deformity of the wall of the stomach. Microscopically there is characteristic syphilitic endarteritis obliterans, with perithelial lymphocytic infiltration; the mucosa is atrophic and the other coats are hypertrophic. Symptomatically, syphilitic differ from benign ulcers in the absence of relief from taking of food or alkalis, in the preservation of good appetite associated with vomiting, and in the result of the therapeutic test. Large gummatous masses or cicatricial contractions following extensive ulceration simulate carcinoma as regards the clinical history of the findings made at x-ray examination and at operation.

654. Syphilitic Mastitis.

BURNIER (*Paris méd.*, April 9th, 1921) suggests that syphilitic mastitis is more frequent than is generally supposed. A study of the literature shows that it may develop at all stages of acquired syphilis, and even in the inherited disease, the dates of its appearance varying from the second week to the thirty-second year. Burnier has collected 9 cases occurring in the early secondary stage, 8 in the late secondary stage, 10 in tertiary syphilis, and 3 in the inherited disease. Owing to the physiological activity of the gland it is a little more common in women (19 cases) than in men (10 cases). Pregnancy, however, does not appear to favour its appearance, only one example of its occurrence in pregnancy having been recorded. It is usually unilateral (21 out of 32 cases). Clinically two distinct forms are encountered. There may be a distinct infiltration affecting one or more lobes of the gland, and the breast is enlarged to twice or three times its ordinary size. The swelling, which is firm and sometimes of a board-like consistency, gradually merges into the healthy glandular tissue. Its size varies from that of a hazel nut to that of an orange. In other cases, in place of a diffuse infiltration there are distinct circumscribed nodules, usually six to eight in number, but sometimes single. The skin usually preserves its normal colour, but sometimes it is reddened when the tumour is adherent to it. The mastitis may assume an acute course and end in suppuration, but usually it becomes completely absorbed as the result of specific treatment. The axillary glands often escape, but may become involved in some cases. The

diagnosis between syphilitic mastitis and cancer of the breast may be very difficult. The diagnosis in such cases is established by an inquiry into the history, the investigation of concomitant syphilitic lesions, the Wassermann reaction, and the result of specific treatment.

655 Malformations of the Anus.

DRUCK (Med. Record, April 2nd, 1921) considers malformations of the anus under five divisions. (1) Entire absence, from failure of the proctodæum to invaginate; (2) abnormal narrowing; (3) occlusion, partial and complete; (4) abnormal opening upon the skin; (5) opening into the vulva, perineum, or scrotum. In entire absence of the anus external skin markings bear no relation to the point of termination of the rectum above, and therefore a careful perineal dissection is required. Symptoms of acute intestinal obstruction develop in a couple of days, the absence of meconium being followed by restlessness, abdominal distension, cyanosis, and eventually faecal vomiting. In narrowing of the anus the canal is constricted at some part between the rectum and the anal opening, or such narrowing may extend the whole of the length. Some individuals go through life with partial occlusion, merely complaining of constipation. Diagnosis is difficult because liquid faeces and gas are passed, and it is only later, when the faeces are formed, that any disturbance is noticed. Membranous occlusion consists of a diaphragm across the canal, and may be complete or partial, the latter being frequently met with. When complete the diaphragm resembles the hymen, and is thin and flexible, bulging with meconium if the rectum is normal above.

656 Vertebral Osteomalacia

EISLER and HAAS (Wien Klin. Woch., February 10th, 1921) describe a form of osteomalacia affecting the vertebral column, of which a large number of cases have recently occurred in Vienna. The disease usually affects both sexes equally, and is most frequent in middle life. It starts with pain in the back, especially in the sacral region. In some cases the pain affects the whole of the vertebral column and radiates like neuralgia or sciatica. The patients all agree that the pain is particularly violent on rising from the sitting posture. In an advanced stage the patients complain of prostration, tremors in the legs, inability to work, and insomnia. Sitting down is avoided as far as possible, as this position causes an increase of pain in the back and sternum. Intense pain also occurs in the recumbent position, especially in changing from one side to another. Finally, the patients are unable to stand or walk, and become bedridden. The symptoms at first are always regarded as manifestations of rheumatism or neuralgia, and it is only after various bath cures and physical therapy have proved unsuccessful that a vertebral affection is suspected. On examination a moderate total kyphosis of the vertebral column is found, with tenderness on pressure, of varying localization, but most marked in the sacral region. Passive movements of the vertebral column are limited in all directions. Active movements, especially bowing, cause severe pain. X rays show more or less deficiency of calcium, with consequent deformity in the bodies of the vertebrae, according to the severity of the case. Treatment consists in the administration of increasing doses of phosphorus, combined in severe cases with orthopaedic appliances, such as a plaster of Paris jacket or a corset. Good results are also said to have been obtained from the use of the quartz lamp.

657. Oesophageal Stricture treated by Continuous Dilatation

MOSSAJO (La Cronica Med. and Arch. de Med., Cirug. y Especialidad, March 1st, 1921) records the case of a man of 24 in whom, a few days after the swallowing of caustic potash, an oesophageal stricture prevented the swallowing of all but a little liquid food. Senn's gastrostomy having been performed, he was fed through the catheter for one month, and then made to swallow a bullet, to which a silk thread had been attached. The bullet having been located in the stomach by means of Bräun's oesophagoscope, a very fine rubber sound was fixed to one end of the thread; by pulling on the other the sound was introduced within the strictured area, where it was allowed to remain for thirty minutes on the first day and for increasing periods of time on the successive days when the manoeuvre was repeated. In two months it was possible to introduce a bougie of normal calibre, which was left *in situ* for twelve hours. Normal conditions were restored at the end of three months' treatment.

OBSTETRICS AND GYNAECOLOGY.

658 Auricular Flutter and Fibrillation in Pregnancy.

THOMAS (Journ. Amer. Med. Assoc., April 30th, 1920) states that he has been unable to find any record in the literature of cases of cardiac arrhythmias in pregnancy. In reporting a case attended in the Presbyterian Hospital, New York, he calls attention to the possibility of successful treatment of certain types of tachycardia that threaten the lives of pregnant women. The electrocardiographic diagnosis was auricular flutter with 2:1 heart block; the patient was six months pregnant, and was semi-comatose, with much dyspnoea, orthopnoea, and cyanosis of the lips. The heart rate was about 180 and regular, a short, rough systolic murmur could be heard at the apex, transmitted for a short distance into the left axilla. The pulse was very feeble and thready, and could not be counted with accuracy, but was approximately 180 and regular. The blood pressure was not readable. The patient was given an initial dose of 1 ccm. of a digitalis preparation intravenously, followed by the same dose given intramuscularly every four hours. On the next morning, while the patient was being examined, her heart rate dropped suddenly from 165 to 112, becoming at the same time quite irregular. The electrocardiogram at this time showed auricular fibrillation. The patient had received up to this point the equivalent of 105 minims of tincture of digitalis in a period of twenty-four hours. Her dyspnoea was less marked, cyanosis had vanished, and she appeared much brighter. The improvement continued, but on the twenty-second day the electrocardiogram showed characteristic auricular fibrillation. At the seventh month she was delivered of a dead foetus, weighing 5½ lb. The labour was uncomplicated and conducted without an anaesthetic. At no time did the heart rate exceed 105. The patient left the hospital with instructions to take 15 minims of tincture of digitalis three times a day. When last seen, six months later, her condition was excellent, she was doing light housework without discomfort, and had dyspnoea only after considerable exertion. The rate of the apex beat was 100, it was most irregular, and the pulse rate was 76.

659 Accidental Haemorrhage.

THIRTY-FOUR cases of premature detachment of the normally situated placenta (accidental haemorrhage), with histological examination, formed the basis of a communication to the Vienna Obstetrical Society by FRANKL and HIES (Zentralbl. f. Gyn., April 23rd, 1921). Inflammatory or degenerative alterations of the decidua, endometrium or myometrium, according to these authors, play no part in the etiology; placental detachment in the third stage of labour being attributed to effusion of blood into the spongy tissue of the placenta, accidental haemorrhage is regarded as due to any cause or combination of causes which brings about prematurely hyperaemia in this region. Such causes may be (1) mechanical—too short an umbilical cord, for example, or traction on the membranes during protracted labour; (2) premature dilatation of the placental vessels—induced, for example, by rupture of the membranes in cases of hydramnios, by birth of a first twin, by alterations in blood pressure following trauma, or by maternal circulatory disturbances, as in exophthalmic goitre; (3) abnormal permeability or friability of the placental tissue, in cases of chronic nephritis or nephropathy. It is not possible to lay down standard lines of treatment; regard must be had not only to the general condition of the patient, but also to the degree of cervical dilatation present at the moment of placental detachment. Rupture of the membranes, sometimes useful, may in certain cases be dangerous, it has therapeutic value in cases only of partial and marginal detachment. In the occasional cases in which the accidental haemorrhage coincides with transverse presentation or contracted pelvis, the treatment must be adapted to the co-existing complication. Vaginal Caesarean section may be performed in cases occurring early in or previous to labour; vaginal hysterectomy may be carried out where there is a considerable degree of uterine atony. Frankl and Hies have found, however, that the use of the vaginal route for operation is subject to the significant drawback that intraperitoneal haemorrhages (free or circumscribed) may be overlooked; laparotomy followed by Caesarean section or hysterectomy is therefore often preferable. Total extirpation of the unopened uterus is recommended in every case in which the uterus is greatly stretched and thinned, or its wall noticeably infiltrated with blood; in

such cases, conservation of the uterus carries with it the risk of subsequent atony with severe bleeding or other complications in the early or late puerperium.

660.

Acute Inversion of Uterus.

HUNTINGTON (*Boston Med. and Surg. Journ.*, April 14th, 1921), in discussing the etiology of acute puerperal inversion of the uterus, considers that the insertion of the placenta in or near the fundus is the main underlying factor, since the extreme rarity of the condition coincides with the rarity of such placental implantation, and the frequency with which forcible expression is used points to this factor as having very little to do with its causation. Symptomatically profound shock, excessive haemorrhage, and severe pain may be present, though in some of these symptoms may be absent, a sign being the absence of any uterine contraction through the abdominal wall. In cases where there is any shock or undue bleeding, and the typical spherical mass behind which the hand can easily pass cannot be felt through the abdominal wall, a vaginal examination should be made. The characteristic feature of being able to pass the hand behind the mass and grasp the fundus in the hollow of the hand is most important. If diagnosed early the mass can be pushed back and the hand held inside until normal contraction takes place, but if it cannot be replaced, immediate laparotomy and traction from above, with direct transfusion, should be performed. When several days have elapsed and replacement after laparotomy fails, a hysterectomy may be necessary or reinversion performed after opening the vesico-uterine peritoneal pouch, stretching the cervix from side to side, and making an incision through the cervix and uterus to within one-third of an inch of the fundus. The possibility of a weakening of the fundus by its being the placental site should be borne in mind in expressing the placenta from above.

661. "Eclampsia" Fits in a Case of Chronic Nephritis after Decapsulation of Kidneys.

ANDÉRODIA and DARRIGADE (*Journ. de Méd. de Bordeaux*, March 10th, 1921) report the following case: A woman, after one normal labour and two miscarriages, had an acute attack of nephritis. She again became pregnant, and at the seventh month had an "eclampsia" fit, and labour was induced. Six months later Professor Pousson operated for the chronic nephritis and performed a bilateral decapsulation of the kidneys. Nine months afterwards the patient was admitted to hospital, when she was seven and a half months pregnant. In spite of the previous treatment she again had fits, and pregnancy was terminated. This case illustrates, according to the authors, the importance of chronic nephritis in the etiology and the severity of eclampsia. It further shows that in some cases decapsulation may not help in subsequent pregnancies.

PATHOLOGY.**662. Abortive Treatment of Experimental Syphilis.**

VECCHIA (*Il Policlinico*, Sez. Prat., March 14th, 1921) carried out the following experiments on rabbits. Having produced two initial lesions in one animal (rabbit A), he inoculated with the material a first series of rabbits (B, C, D, E) in the scrotum. Rabbit D was kept as a control, and rabbits B, C, E were given intravenous injections of novarsenobenzol 0.01 cg. per kilogram on the second, fourth, and sixth days after infection respectively. While the control rabbit D developed two syphilomata at the inoculation site forty days after inoculation, the rabbits B and C remained completely immune from syphilitic manifestations, and when killed three months after inoculation rabbit C showed no naked-eye or microscopical lesions. On the other hand, the rabbit E, which had been treated on the sixth day after infection, developed an ulcer at the inoculation site on the twenty-fifth day, with corresponding adenitis of the inguinal glands, and on the fiftieth day a definite syphiloma in both testes appeared, from which the *Spirochaeta pallida* was obtained. Vecchia then carried out a second series of experiments with rabbits F, G, and H, which were treated on the first, third, and fifth days after infection with intravenous injection of 0.03 cg. novarsenobenzol per animal, or 0.01 cg. per kilogram, with negative results in each case. Finally, rabbit B of the first series and rabbits F, G, H were again inoculated with syphilitic material rich in spirochaetes and did not receive any treatment. On the twentieth day rabbits G and H and on the thirty-fourth day rabbits B and F

developed primary lesions containing spirochaetes. Vecchia suggests that the abortive method of treatment described is specially suitable in cases of professional inoculation of syphilis, such as may occur in doctors and nurses.

663. Action of Intravenous Injections of Glucose and Gum Arabic Solutions on Diuresis.

CORI (*Wien. klin. Woch.*, April 14th, 1921), as the result of experiments on dogs and observations on man, comes to conclusions: (1) Intravenous injection of solution has a marked diuretic action undant discharge of chlorides into the blood takes place, accompanied by a correspondingly large amount of water. If, as the result of a diet poor in chlorides, a smaller amount of chlorides is discharged, the diuretic effect is also less. (2) The increased excretion of chlorides from the tissues into the blood is still present even after twenty-four hours. (3) Absorption and excretion of salts (nitrates) introduced into the stomach are abnormally accelerated as the result of the injection of glucose. (4) In man, solution of glucose does not have a diuretic action, as the chlorine is more firmly anchored in the tissues. (5) Intravenous injection of 7 per cent. gum arabic reduces the excretion of sugar in diabetes. The amount of urine is also much reduced. (6) The same solution of gum arabic causes a slighter excretion of iodine in the dog than in a control animal. (7) Gum arabic solution has only a weak diuretic effect in the dog, and does not produce a discharge of chlorides into the blood. Unlike glucose diuresis, therefore, there is only a water diuresis, and not a diuresis of chlorides as well.

664.

The Pathogenesis of Myoclonus.

ACCORDING to PILOTTI (*Il Policlinico*, Sez. Med., April 1st, 1921), who records a fatal case in a woman aged 37, with the autopsy findings, the pathogenesis of myoclonus is still obscure in spite of all the hypotheses put forward to explain it, and in spite of all the anatomical lesions with which an effort has been made to associate it, whether lesions were found in the cortex, the spinal cord, or other regions of the central nervous system. As a general rule cases of myoclonus, whether they have a chronic course like Pilotti's patient and a few similar ones which have been studied histologically, or an acute course like the cases of epidemic encephalitis of the myoclonic type, present as a rule too great a complexity, both in their clinical and histological manifestations, to allow one to distinguish with certainty those lesions which are alone responsible for the motor disturbances from those which have nothing to do with them. Pilotti is of opinion that the origin of the myoclonic movements is not confined to a single area such as the cortex, spinal cord, or mid-brain, but that in addition to myoclonic movements which are undoubtedly of cortical origin, other lesions in the cord or mid-brain may cause these motor disturbances by a hitherto unexplained mechanism.

665.

Spirochaetosis Icterohaemorrhagica.

DARGEIN and PLAZZ (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, March 17th, 1921) record a case of spirochaetosis icterohaemorrhagica in a sailor at Toulon which was remarkable for the following points: (1) Absence of an epidemic focus; as the man had not left Toulon for some time and had been living in a place swarming with rats, the supposition of contamination elsewhere could be excluded. (2) None of his comrades was affected. (3) In spite of numerous careful examinations it was impossible to find the *Spirochaeta icterohaemorrhagica* in the urine on direct examination, and the nature of the jaundice could only be determined by inoculation of a guinea-pig. The writers therefore insist on the importance of not excluding the diagnosis of spirochaetosis icterohaemorrhagica on the negative result of examination of the urine, and recommend that inoculation of a guinea-pig, or, failing that, the serum diagnosis or reaction of neutralization (Martin and Pettit), should always be performed.

666. Cancer of the Stomach with Remarkable Metastases.

VAN DER PERK (*Nederl. Tijdschr. v. Geneesk.*, January 1st, 1921) records a case in a woman, aged 47, in whom the most prominent symptoms during life were fracture of the right clavicle and sixth rib and blood in the stools. There were no gastric symptoms. The autopsy showed a carcinoma near the pylorus and metastases in both ovaries, the right clavicle, pleura, and paravertebral tissue from the third to the sixth rib. No lesions were found in the liver, spleen, pancreas, intestine, uterus, or omentum.

THE TALGAI MAN—THE EARLIEST KNOWN AUSTRALIAN.—The fossil skull, discovered at Talgai, S. Queensland, on the right, and the super-imposed outlines of this and of the face of a modern aboriginal Australian on the left, show very similar distinctive traits possessed by both, though certain characters in the fossil are more primitive in type than the same characters shown in the present-day outlines. The forehead is seen to be receding, the degree of prognathism is very striking, the orbits are large and quadrangular. The palate of the Talgai man is very long, the series of molars are almost parallel. These features may be seen in modern Australian natives, but not in so high a degree; indeed, no human race, with the single exception of the Pitddown, presents so markedly primitive a type in this respect. In some regions this Talgai skull shows certain simian characters, while the brain had long been fully human—a condition which seems to provide

confirmation of the theory that man has evolved and differentiated himself by developing a human type of brain first, his other bodily characters becoming definitely human later and as a consequence of this. The progenitors of the Talgai man must have been well endowed mentally, since they are believed to have solved at so remote an epoch the problem of reaching Australia from the mainland; it is to their pioneer efforts at exploration that the first peopling of the island continent is probably due. At present, the only other evidence of man antiquity in Australia is that provided by a human molar from New South Wales.

Iodolysin

**IN RHEUMATISM &
RHEUMATOID
ARTHRITIS**

'Iodolysin' is a soluble compound of Thiosinamin with Iodine and contains 43 per cent. Thiosinamin and 47 per cent. of Iodine. The preparation has been very successfully used in the treatment of Rheumatoid Arthritis and Arthritis Deformans.

A Striking Report

"It may interest you to know that I have been using it ('Kapsol' 'Iodolysin') in a case of Rheumatoid Arthritis with very marked success. I saw the case first about a year ago when she had been a complete cripple for over six months. She was discharged from a hospital in ——— as incurable. I found her suffering from *pyorrhea alveolaris*, which I treated with an auto-vaccine and afterwards gave her the 'Iodolysin,' and that only, in varying doses. She can now walk into her garden, goes up and down stairs, dresses her own hair, and her joints are quite free from pain and deformity. She continues to take one 'Kapsol' daily. I think the result is most satisfactory."

ON

LIMPS IN CHILDREN:

THEIR RECOGNITION, ORIGIN, AND TREATMENT.

BY

JOHN FRASER, M.D., F.R.C.S.,

SURGEON TO THE ROYAL HOSPITAL FOR SICK CHILDREN; ASSISTANT
SURGEON, ROYAL INFIRMARY, EDINBURGH.

PERHAPS I ought to apologize for dealing with a subject which the orthopaedist has come to regard as his own, but I am going to make no apology, because I speak from the point of view of the general surgeon—of one who has to spend much of his time in the wards of a children's hospital, and who is constantly experiencing the practical difficulties of which I speak.

In discussing the subject I shall attempt to illustrate certain distinctive limps by means of cinematograph pictures, a method of illustration which we are finding of increasing value in teaching the student, and also (if I may say so) of humbling the surgeon. The average surgeon is notoriously an optimist—I suppose his work makes him such, for someone has said that where there is no faith there can be no surgery. But, nevertheless, I am afraid that many of our surgical results are seen through rose-coloured spectacles. We forget the original picture, and we take too much credit for our post-operative results. A pre-operation film is an excellent corrective!

The Importance of Recognizing and of Investigating a Limp.

We have all had the experience of being asked to see a child because it is limping, and I know few more difficult problems than that of definitely localizing the site and the origin of the disorder. The younger the patient the more difficult does the problem become. He may be able to give us no assistance, and frequently he is actively antagonistic; the story of the parents may be garbled or actually misleading, and in many cases the elucidation of the mystery depends entirely on the clinical acumen and the trained observation of the examiner.

It is certain that the average parent has no sympathy with the doctor if he is unsuccessful in solving the mystery, or if he makes a mistake in diagnosis. To their minds the problem should present no difficulties, and therefore they make no excuse for error; but, as I have said, and as I shall attempt to show, few more difficult problems come under the notice of the specialist or general practitioner.

It is obviously essential that the origin and nature of the limp should be determined before adequate treatment can be carried out. Purely empirical treatment is rarely successful.

There is yet another reason why one urges the early and thorough investigation of a limp, and, though I mention it last, it is, from the practical point of view, the most important—early recognition and definition spells early treatment, and the pathology of many limps is of such a nature that early treatment means a good result, while delay may entail functional disaster.

A General Consideration of the Possible Causes of a Limp in a Child.

When a limping child is brought to notice and one is asked to furnish the diagnosis, I believe that it is a good plan to consider the problem from a logical standpoint—to say to oneself that there are certain groups into which limps may be classified. It is the first duty of the observer to recognize into which class the case falls. Having decided this more general consideration, it naturally becomes an easier matter to explore the various possibilities of the larger group, and to conclude with a local and exact diagnosis. We shall see the application of my argument in a moment when I have elaborated a scheme of classification.

Classification of Limps from the General Point of View.

This question of the general scheme of classification of limps is by no means as easy as it might appear. As far as I know, the question is not specifically considered from

this point of view by either the orthopaedist or the general surgeon, but it seems to me that there are certain general classes of limps, and when a limping child is brought to me for an opinion, the first thing I do is to attempt to put the limp into its general class. What are these general classes? I would venture to suggest that they may be tabulated as follows—and of course there is nothing original about the classification—it is merely common sense:

- I. Functional limps.
- II. Painful limps.
- III. Flaccid limps.
- IV. Spastic limps.
- V. Mechanical limps.
- VI. Stiff limps.

Let me in a few words explain what I mean by these relative terms.

Functional limp is rare in children, especially in the early years of life. If met with, it is generally found in girls over the age of 8 or 9 years. It has certain characteristics of stiffness, of variation in degree and of exaggerated symptoms unaccompanied by any discoverable lesion. It forms a distinctive class of limp, as I shall attempt to show, but its diagnosis must only be made after the careful exclusion of other possibilities.

Painful limp, or the "hurrying limp," as it is sometimes called, has as its essential feature the reduction to a minimum of weight-bearing on the limb. The source of the pain may vary from a blister of the foot-sole to an acute infection of the hip-joint. The degree of limp will be modified according to the situation and degree of the pain.

Flaccid limps. Under this term I include those gaits in which the distinctive feature is muscular weakness, from whatever cause it may proceed, whether the central nervous system, the peripheral nerves, or the muscles. The possible origin may have such varying sources as poliomyelitis, a peripheral nerve lesion, or a muscular dystrophy.

Spastic limps are generally characteristic, and there is rarely any difficulty in their recognition. The picture of the stiff and jerking gait is so distinctive that once seen the impression remains. Almost without exception they are the result of an error—congenital, inflammatory, or traumatic—of the central nervous system.

Mechanical limps. It is with this variety that I have had the greatest difficulty in nomenclature. I feel there must be some more expressive and representative term, but I cannot light upon it, and therefore, in place of a better, I have used the word "mechanical." By using this term, I mean to imply that the limp arises from an error in alignment of the various portions of the osseous system which forms the skeleton of the lower limbs, and of the possible errors in alignment there are these common ones:

1. Congenital relation to the plane of the pelvis.
2. Acquired relation to a similar plane.

The mechanical limp may therefore have such widely divergent origins as a congenital dislocation of the hip, coxa vara, bow-legs, knock knee, and former hip-joint disease, which, though cured, has resulted in abduction or adduction of the limb. In the mechanical limp, as I intend it to be expressed, there is no muscular weakness and no joint pain—it is purely the result of a mechanical error in the relationship to one another of the bones which form the lower extremities.

Stiff limps. This is the last general group I propose to recognize. It depends upon an ankylosis of one or other of the joints of the lower extremities—hip, knee, ankle, or tarsal joints.

Now that I have given this rough general classification let us reconsider the position.

By closely watching the child as it walks in front of you I believe it is possible to classify the limp into one or other group, and this by simple observation alone, without putting the hand upon the limb. Of course, there may be some overlapping in the classification. For example, I can quite well imagine a gait or limp which is "painful," and yet has some mechanical error which demands that it should be included in the "mechanical" class. Similarly, a mechanical limp may be combined with a stiff limp. I need not, however, enlarge upon these combined types.

Distinctive Features of Each Class.

Each variety of limp has one or more distinctive features by which we are able to recognize it.

The functional limp would appear at first as though it were a painful limp of an exaggerated degree, but it has two features which should at once arouse suspicion. The first is that every now and again the heel is quite firmly brought to the ground. Now, in a true "painful" limp this manœuvre is most carefully avoided, except in the rare instances in which the origin of the pain lies in the fore part of the foot. The second distinctive feature of the functional limp is its variability in degree. At one moment it may be of the most exaggerated type, at another the limp is lost entirely, to be instantly reacquired. These two features, combined with the fact that on careful physical examination no lesion can be found, generally justify one in classifying a certain variety of gait or limp as "functional."

The painful limp. When a child has a diseased and painful focus in a limb it is most likely that pressure will increase the pain; therefore the distinctive point about the painful limp is the quite apparent unwillingness of the child to allow the full weight to be borne by the limb. It reduces to a minimum the amount of time during which the limb has to bear pressure, and some orthopaedists have descriptively termed it "the hurrying limp or gait." There are two other features generally present in painful limps. The one is that in order to avoid any jarring of the limb the heel is kept off the ground; exceptions to this rule are those cases in which the situation of the pain lies in front of the ankle-joint. The other characteristic feature lies in the fact that the various joints of the limb are held in a semi-flexed condition. This has as its explanation the attempt to diminish any jarring of the limb.

The flaccid limps are generally characteristic, and, according to the various groups of muscles which may be affected, different types of the flaccid limp appear. When the muscles round the ankle-joint are involved there is a distinctive high-stepping gait, with exaggerated lifting of the limb, in order to carry the paralysed foot clear of the ground. Around the knee-joint the extensor group of muscles are those most commonly affected, and in these cases the limp is very typical. The arm of the affected side is brought into use, and the knee is maintained in the extended position by keeping the hand firmly pressed against the front of the knee or thigh, the body being thrown forward to enable this manœuvre to be carried out. If the muscles round the hip-joint are extensively paralysed it is likely that the child will be unable to walk without artificial support; if, however, the paralysis in this region is limited and walking is possible, there is a characteristic outward swing of the limb with the foot in an everted position.

In all the flaccid paralytic limps the distinctive feature is the want of control over certain movements, with often exaggerated manœuvres of the healthy muscular groups.

The spastic limp. I need say very little of the characteristics of this type. The spastic condition of various groups of muscles is responsible for the spastic or "stotting" limp. The gait is forcible and jerky. It is well illustrated in spastic equinus, and it finds its most marked degree in the spastic diplegia or Little's disease. It is a limp which, once appreciated, is always easy of recognition.

The mechanical limp. I have defined the mechanical limp as being dependent upon an error in alignment of the bones which collectively form the skeleton of the lower limbs—I include therefore the pelvis. Of the possible errors in alignment there are three which I would mention as being responsible for characteristic mechanical limps—

Pure shortening of the limb.

Adduction of the limb in relation to the plane of the pelvis with apparent shortening, and

Abduction of the limb with apparent lengthening.

In the pure mechanical limp the limb is used as confidently as a normal limb—there is no muscular weakness, and no pain; the limp is therefore the result of the patient's effort to overcome the mechanical error which deformity or former disease or injury has induced.

If the error lies in pure shortening of the limb (as is

evidenced in congenital dislocation of the hip or in a fracture with shortening) there is a simple sinking of the pelvis towards one side. The sinking limp is best illustrated in a case of congenital dislocation of the hip, because in this condition not only is there shortening present, but, owing to the imperfect fixation of the hip, a further sinking is induced as weight is put on the limb.

If the limp arises from abduction of the limb in relation to the pelvis, the deformity may be wonderfully disguised. There are two points, however, which distinguish it—the patient walks with a broad base, keeping the feet well apart, while as each step is taken on the affected limb the body sinks towards that side. Frequently also the whole limb on the affected side is held stiffly, while, it is swung outwards and forwards as progress is made. As a matter of fact, the pure mechanical limp of abduction is rarely seen. An abduction stiff limp is much more common. Here there is an ankylosis at the hip-joint, and, as the result of treatment of such a condition as a tuberculous hip, ankylosis has occurred in an abducted position.

Adduction of the limb produces one of the most characteristic and most distressing of all limps. To be able to walk efficiently the patient must go through a complicated manœuvre, and as each step forward is taken a series of movements is really carried out. From the adducted position the limb is first abducted, and to do this the body is tilted toward the opposite side; the limb is now adducted to bring it as far as possible parallel to its fellow, the pelvis and the body sinking towards the affected side. As these lateral movements are in progress, forward movement is at the same time being carried out. It is easy to imagine the exertion and the deformity entailed in an adduction mechanical limp.

Stiff limps. The question of stiff limps I shall dismiss in a word. Whenever a joint of the lower limbs is ankylosed or stiff, a limp results. Stiff tarsal-joints and ankle-joints give a characteristic wooden appearance to the walk. This deformity is often wonderfully disguised. The knee, if ankylosed in a position of slight flexion, may give rise to wonderfully little disturbance in the walk, but a characteristic stiffness is always noticeable. The limp of an ankylosed hip is a combination of the stiff gait and the mechanical gait, according to the position in which the limb is ankylosed, and the shortening which may be present.

Examination of the Limb after Classification of the Limp.

My thesis up to this point has been that by observation of the method of walking it is possible to classify the majority of limps into certain groups, and, when this has been done, a great advance has been made towards the final diagnosis. But this is not sufficient—it is necessary now to localize the exact situation of the limp and, if possible, to come to an opinion regarding the pathological condition which is at fault. Now these points of knowledge can only be gained by a close study of the history and by a careful examination of the limb.

There is little I need say in regard to the history: while the parents' story is often misleading in so far as an injury, imaginary or real, always bulks largely in their eyes, one must remember that the natural maternal instinct of the mother qualifies her as an exceptionally shrewd observer. The history may be of great importance in recognizing the congenital nature of a limp. But, apart from the consideration of the history, the ultimate diagnosis will depend on the accurate examination of the limb.

The child, who should be stripped, having walked before me, I begin by noting the position of the limb as a whole—does it lie in a normal or in a deformed position? I survey the skin for any pathological appearance; I estimate by comparison of the two limbs the degrees of muscular development or wasting, and here I bear in mind a very simple, yet a very important, clinical fact—namely, that if the muscles of a segment of the limb are wasted (paralysis and dystrophies being excluded), there is some pathological change in the joints and bones over which these muscles play.

Any alteration in the outline of the limb is no longer for as being representative of an abscess or collection of fluid. My eyes are now directed to the joints of the limb;

the relative positions of the bony points are estimated, any joint fullness or error in position is noted.

Only when I have exhausted the observations of which my eyes are capable do I attempt to use my hands, and the use I make of them is largely to confirm what my eyes have already told me. I estimate by feel the character of the skin, I investigate any local swellings, I carefully palpate in turn each structure which collectively forms the limb. I therefore palpate the subcutaneous tissues, the muscles, the bones, and the joints. For example, my hands will tell me whether a swelling in relation to a joint is osseous, is due to a thickened synovia, or to the excess of fluid within the joint. I very carefully estimate the relative position of the bony points around a joint—this in view of a dislocation being present.

I then proceed to the investigation of the muscular functions of the limb. As far as possible, voluntary movement of the various groups of muscles is elicited. In the child this may be difficult, but by a little ingenuity and the exercise of patience the difficulty is overcome.

The joint movements are now investigated—first actively, then passively. Each movement of which the joint is capable is tested. Examination of the passive movements of the joint is, perhaps, one of the most important of all the stages of the survey; the results bulk so largely in the differential diagnosis. For example, I can imagine four pathological conditions in relation to the hip-joint, all of which are associated with a limp, and from examination of the passive movements of the hip-joint alone I can form at least a provisional distinction between them. Let me illustrate: If I am dealing with early tuberculous disease of the joint, flexion and rotation are limited by muscular rigidity. If Pott's disease (osteochondritis deformans juvenilis) is the condition present, flexion is perfect, while rotation is limited; if there is a congenital dislocation of the joint, abduction and external rotation are limited; in *coxa vara* abduction only is affected.

I now proceed to measurement of the limb. First, the ilio-malleolar measurements are taken, and, if true shortening is shown to be present, I localize the situation by subdividing the original measurements into three—from the adductor tubercle to the median malleolus, from the tip of the great trochanter to the tubercle of the tibia, and, thirdly, by the estimation of Bryant's triangle or Nélaton's line. In one of these three areas I shall find the shortening. The second group of measurements, as estimated from umbilicus to median malleolus (the iliac spines being on the same plane), will give me an estimate of apparent shortening or apparent lengthening—in other words, of abduction or adduction of the limb.

There is another point in the examination of the limb to which I would allude. There are certain muscles which pass into the limb from a higher origin, and of these the psoas is the most important. It is therefore always wise to include an examination of the lower abdominal viscera and the lumbar spine in the routine investigation. Tuberculous disease of the lumbar spine with associated contraction of the psoas muscle produces a limp which is closely similar to that produced by hip joint disease.

Up to this stage the examination requires no special apparatus or facilities, and by the time this stage is reached the diagnosis will probably have been made. The further examination ought to be rather confirmatory than otherwise; it will take the form of radiographic examination of the bones and joints of the limb. In these days, when x-ray facilities are so general, I am afraid we tend to resort to them too readily. If we do, then our clinical acumen will suffer. It is wiser to treat them as a diagnostic luxury, and to use them as confirmatory or otherwise of a clinical diagnosis.

I have no intention of attempting to describe the distinctive limp in individual diseases—I question very much if such a thing is feasible. My idea has rather been to look at the problem from a general aspect, and to attempt, if possible, to formulate a scheme upon which the problem may be worked out. If I may put the scheme into a few words (and after all it is so simple that perhaps the word "scheme" is too pretentious) the idea upon which I work is primarily to classify the limp, and this classification may be made entirely by observation of the gait; the type having been recognized, detailed examination

of the limb will generally succeed in localizing the site and the nature of the condition which has produced the limp.

The Treatment of Limps.

In this connexion, of course, it is only possible to speak in general terms. Each individual condition must be treated upon independent and special lines; but it is possible to express general ideas on the subject.

If it is decided that the limp is functional, the less the attention paid to it the better. Sympathy and local treatment will probably intensify and prolong it. The child responds readily to suggestion treatment. I have seen a girl with a pronounced functional limp walk normally after a short period of suggestion treatment. [A film representative of this case was shown.]

Painful limps call for early and careful treatment. The exact localization and pathological condition of the disorder must be recognized, and, this having been done, painful limps are treated by rest and immobilization of the part. We may take it, therefore, that for the limps recognized as being in the painful class, efficient rest of the limb is the first essential in treatment. Later, and depending on the pathological condition at fault, more special surgical treatment may be demanded, but with these indications I do not propose to deal.

Flaccid limps suggest wide possibilities of treatment; as the majority owe their origin to poliomyelitis, I would remind you that prevention is better than cure. During the acute stage of the illness, and subsequently, accurate splinting of the part in such a position as to relax the weakened muscles may well obviate the later development of a limp. When the limp has become established, mechanical treatment and operative treatment offer the most promising lines of treatment. In this connexion in recent years surgery has made enormous strides—tendon transplantation, silk fixation, and arthrodesis are often successful in restoring function to an otherwise useless limb.

Mechanical treatment by splints in children is often disappointing. The appliances should be of the simplest possible description, but the weight, the effort entailed in their use, and the education required are often detrimental to success. The present aim of surgery is to reduce to a minimum the use of mechanical appliances.

Spastic limps call especially for educational efforts. Occasionally surgery steps in beneficially with such simple procedures as tenotomy and tendon lengthening, but the intelligent use of corrective splints applied at night and careful education during the day produce good results.

Mechanical limps call for a special word of warning, and it is this: I believe that as a general rule it is a wrong principle primarily to condone a mechanical limp by some mechanical appliance. The common essential feature of most mechanical limps is shortening, and the aim should be to correct, if possible, the mechanical error which is producing the shortening, rather than to disguise it by such a procedure as heightening the boot sole. This should only be done as a final stage in treatment and after all other errors, such as adduction, etc., have been corrected. If raising the boot sole is the only remedy adopted, it may lead to a progressive increase in shortening.

Stiff limps generally call for little in the way of treatment. It is essential, however, that the part affected should be in the best possible position for subsequent ambulation. In the treatment, therefore, of any joint condition which may end in ankylosis, it is essential that care should be taken so to arrange matters that where ankylosis subsequently occurs, the joint concerned is in the best possible position—the ankle should be at right angles to the leg, the knee very slightly bent, and hip in moderate abduction, with slight outward rotation of the limb.

At one time we hoped that arthroplasty offered a possible method of restoring movement to ankylosed joints, but I am afraid that in the lower limb, at least, the results have been disappointing. We realize that there are worse things than a joint firmly ankylosed in a good position.

These are some of the points which have occurred to me in discussing the subject of limps. There is nothing new or original in the matter brought forward: I have merely attempted to put the subject before you in a consecutive light.

RESIDUAL VACCINES:

A NEW TECHNIQUE FOR THEIR PREPARATION, WITH A
DESCRIPTION OF SOME PROPERTIES OF THE
BACTERIAL RESIDUE.*

The detoxication of vaccines has recently attracted considerable attention. Thomson's method¹ depends upon the fact that alkaline solutions dissolve organisms and their toxins whilst mineral acids precipitate the organisms but retain the toxins in solution. The chief merit of this method is that the final concentration ready for administration can be adjusted to any desired strength. Professor H. R. Dean² has shown that a suspension of virulent organisms can be detoxicated by the action of eusol or hydrogen peroxide in weak solution. The author has found it convenient to employ a method which embodies these two principles.

The term "detoxicated" is unfortunately somewhat misleading, and has even caused this type of vaccine to be looked upon with a certain amount of suspicion in some quarters. It has been thought that a preparation which is itself non-toxic cannot be expected to stimulate a protective reaction on the part of the tissues. If this were so, these vaccines might with reason be suspected. But it can be shown that they possess a toxicity of a definite type, and that this toxicity is contained in the bacterial residue which remains after the complete removal of the toxins and endotoxins. It therefore appears to the author to be more in accordance with a true description of them to call them vaccines of the bacterial residue, or more briefly, residual vaccines. The term "toxin" as used to-day has a restricted meaning, and in order to avoid confusion the toxic properties of the residue will be, as far as possible, referred to as the residual toxicity rather than the residual toxin.

Technique.

A sufficient quantity of growth is usually obtained from two or three Petri dishes. The growth is emulsified with about 100 c.cm. of a 1 per cent. solution of phenol in sterilized tap water and the emulsion poured into a tall glass. The volume is noted and the number of organisms per cubic centimetre estimated. From a pipette sufficient 40 per cent. NaOH is added to form a 0.5 per cent. solution. The suspension is then set aside for an hour. During this time the suspension loses most of its opacity and becomes translucent, but rarely quite transparent. Strong HCl is next added drop by drop until the fluid is neutral to litmus, after which one drop of the acid is added for every 10 c.cm. of fluid, which is now opaque once more. Lastly, hydrogen peroxide (10 vols.) is added in the proportion of 1 c.cm. to every 50 c.cm. of suspension.

The vessel is placed in a 55° C. oven and remains there for twenty-four hours, at the end of which time the organisms are found lying at the bottom of the glass as a dull white precipitate. The supernatant fluid containing the oxidized toxins is clear, and should be decanted, leaving the deposit behind. More 1 per cent. phenol is now added to make the fluid up to its original volume and acid added as before—namely, 1 drop to every 10 c.cm. Peroxide is not added. Sedimentation is usually complete in three to six hours. The supernatant fluid is again poured away, the deposit neutralized by 40 per cent. NaOH, and the suspension made up to the required strength by the addition of normal saline, no further phenol being added, so that the final concentration contains phenol in a strength of 0.5 per cent. or less. Since tap water and not saline was present in the residue it might be thought that the final preparation is hypotonic, but the neutralization of the NaOH produces a solution of sodium chloride near enough to the strength of normal saline.

The strength per cubic centimetre and the dosage will depend upon the ratio of residual toxicity to the total toxins present in a culture grown upon a suitable medium. This ratio varies for different organisms, but a safe rule is to make the vaccine 100 times the strength of the corresponding ordinary vaccine, and to commence treatment with a small trial dose. No absolute rule can be laid down. The idiosyncrasy of the patient is just as evident with these vaccines, but as a rough guide it may be said that the initial dose of a residual vaccine should never exceed 1,500 millions.

* The expenses of the laboratory side of this work were assisted by a grant from the Department of Pathology, University of Manchester.

The last stage in the preparation is the sterilization, which is performed in the autoclave by heating for fifteen minutes at a temperature of 120° C. When the bottle is removed from the autoclave a fine precipitate is usually present, the supernatant fluid being almost clear. Both fluid and precipitate react normally to acids and alkalis; the deposit is easily passed into suspension again by slight shaking. Sedimentation is used instead of centrifugalization, because experience proved that to yield results a centrifuge must be of fairly large capacity and be capable of very high speed.

Sedimentation is slower, but the use of Dean's method reduces the washings to two and so tends to equalize matters. The oxidation method cannot be used alone because of its liability to produce a vaccine of inconveniently large bulk. The rate of sedimentation varies with different organisms, but the most refractory can be made to deposit quickly by boiling the alkaline solution for a minute or two, then adding the acid and setting aside in the 55° C. oven as usual. There is no need to repeat the boiling in subsequent washings.

How long the vaccine keeps without deterioration is uncertain, but it is much longer than is the case with thermolabile vaccines. The reaction of one particular vaccine was as strong as ever fifteen months after it was made; another, when nine months old, also showed no change in its toxicity.

Examination of the Precipitate.

The gonococcus was used to investigate solubility in NaOH. An emulsion containing approximately 1,000 millions per cubic centimetre was made with normal saline and a film examined. The cocci were of normal appearance. The suspension was converted into a 1 per cent. solution of NaOH. Much of the opacity immediately disappeared and the fluid became translucent, almost transparent. A film showed cocci present in large numbers with no amorphous deposit.

The suspension was next heated to 55° C. for forty-eight hours and resulted in a perfectly transparent fluid. A film showed cocci in greatly diminished numbers and a large amount of debris. It is difficult to give a precise estimate, but it seemed that about two-thirds of the cocci had disintegrated. It would therefore appear that the translucency is due to swelling of the organisms with an alteration in their light transmitting properties. True solution occurs later after comparatively prolonged action of the alkali. The observations were repeated with *B. coli* and gave similar results.

Reaction on Patients.

It is stated that the toxic symptoms seen with ordinary vaccines do not occur with residual vaccines. This is not in accordance with the author's experience. A local reaction is the most noteworthy feature. Shortly after inoculation a red area, slightly swollen, appears round the site of injection. It is commonly about three inches in diameter and painful to pressure, but not otherwise painful. The constitutional disturbance is variable, but in general is less than that seen with ordinary vaccines.

Clinical Results.

Over two hundred cases have been treated up to the present time, and according to reports received from the clinicians the results have been very satisfactory. There have been failures, but the results on the whole have been better than those one would have expected if the cases had been treated with the older type of vaccine. This is a facile statement, and one is aware that a detailed account is preferable. Circumstances arose by which more exact information was obtained.

A stock ordinary vaccine was required for a few men suffering from chronic bronchitis, and it was decided to treat a further number of patients with residual vaccine. These latter comprised that large group of cases of chronic bronchitis to be found attending the out-patient department of any large general hospital. They could not be said to offer much prospect of success with any form of treatment available to people in their station in life. Cases with severe cardiac or renal complications were excluded, otherwise no restriction was placed upon the age of the patient or upon the origin or duration of the disease; in fact for a period of six or eight weeks the out-patient department was drained for cases.

A large stock of a mixed suspension was collected, and from it was prepared an ordinary vaccine having the following composition:

<i>M. catarrhalis</i> (7)	70 millions per c.cm.
<i>Streptococcus</i> (4)	15 "
<i>Pneumococcus</i> (4)	25 "
<i>Friedländer's bacillus</i> (5)	50 "
<i>B. influenzae</i> (3)	10 "
<i>Hoffmann's bacillus</i> (3)	30 "
<i>M. pharyngis siccus</i> (1)	20 "
<i>Staphylococcus</i> (5)	20 "

The figures in brackets denote the number of sources from which the organisms were obtained. For the sake of brevity this vaccine will be referred to as the "O" vaccine.

The remainder of the stock was converted into a residual vaccine by the method previously described, except that it was divided into three parts, which were each sterilized in a different way. The first part was sterilized at 55° C. by means of 1 per cent. phenol acting at that temperature for twenty-four hours. This was called the "X" vaccine. The second portion was sterilized by heating at 95° C. for sixty minutes, and was called the "S" vaccine. The third part was sterilized in the autoclave, and called the "A" vaccine. Except for the method of sterilization these three vaccines were identical, and were made 100 times the strength of "O."

At this point it might be objected that any merit this type of vaccine may possess is due to a small amount of toxin which has escaped removal. In the case of "X" it would be 1/100th part of that originally present in "O" if, as was the case, the reaction caused by a given volume of either was approximately the same. The point can be discussed forthwith.

When a suspension is detoxicated by simple solution and sedimentation, the deposit is usually in volume 1/10th to 1/15th of the supernatant fluid, and the soluble toxins present in the water of the deposit will therefore be 1/10th to 1/15th of the total toxins originally present. But if the washing is repeated six times, the amount of toxin remaining will be considerably less than one millionth part of their former amount, if simple mechanical washing is the whole explanation.

Further, the reaction is not appreciably less if the organisms are washed twelve times instead of six, or if the author's combined method is used. Lastly, the suggestion does not explain the oxidation process in which the peroxide is evenly distributed throughout the suspension. The theory will not meet the facts. Most bacterial toxins are destroyed by a temperature of 80° to 90° C. The behaviour of the residue will be seen later.

A Series of Chronic Bronchitis Cases.

The results are presented in tabular form, and the intensity of the reactions and the amount of clinical improvement are shown by numerals which have the following significance:

Local Reactions.

0=No reaction.

1=Swelling, no pain; possibly tender on pressure.

2=Swelling with erythema; painful, and stiff on movement.

3=As in 2, but more pronounced. Erythema more than 3 in. in diameter. Shooting pain along arm in addition to pain at site of injection.

General Reaction.

0=No reaction.

1=Slight lassitude, but no definite malaise.

2=Patient feels unwell, with headache and disinclination for food. Malaise disappears in twenty-four hours.

3=Malaise more marked and lasting two or three days.

Degree of Improvement.

0=No improvement.

1=Slight, but clinically evident improvement.

2=Moderate improvement with paroxysms of coughing much diminished.

3=Marked improvement with complete, or almost complete, cessation of nocturnal asthmatic attacks.

Note.—The improvement was estimated by the physician to whom the case belonged and who was not informed as to what type of vaccine the patient had received, or the dosage.

It is recognized that this method of presenting the facts is open to criticism, but it is the only way in which the records of such a large number of cases can be kept within reasonable limits. The use of the minim scale was determined by the available supply of hypodermic syringes.

Analysis of Results.

The "O" results are not put forward here to demonstrate that residual vaccines are superior to thermolabile vaccines—as in fact they are—but to afford a comparison of the general and local reactions, and hence of the toxicity.

The average of the general reactions in the "O" group is slightly greater than that in the "X," "S" and "A" groups, but the local reactions in these latter exceed those in the former group, and are possibly to be explained by the imperfect solution of the bacterial debris with consequent slow absorption, this in turn necessitating a strong local reaction to break it up and pass it into solution.

The reactions of the "A" group prove that a temperature of 120° C. is not detrimental to a residual vaccine, so the "S" results are superfluous, and should be read as part of the "A" group.

A very noticeable feature of the constitutional disturbance caused by the residual vaccines was the frequency with which it was of an intestinal nature. Whenever a "G.R. 3" was produced a disinclination for food was invariable, and in about half the cases was accompanied by some vomiting and diarrhoea. The latter symptoms disappeared in eight to twelve hours after their onset. Diarrhoea alone and of mild degree was common also with milder reactions, but only after the first or second dose. The gastro-intestinal disturbance was never seen in the "O" group, and it would therefore appear that bacterial residues differ from thermolabile toxins in their physiological action as well as in their chemical properties. This phenomenon has been observed with other vaccines of the same type, but only when either the pneumococcus or streptococcus was contained in the vaccine.

Another point which is brought out in the tables is the size of the last dose given. It will be noticed that the "O" group reached an appreciably higher number of minims than any other group, and during the course of treatment one could not help observing that the "O" group tolerated much greater percentage increases of dosage. When weighing this fact it should be recollected that all four groups started with the same number of minims to which they reacted to approximately the same extent.

It is a common method when using thermolabile vaccines to increase each dose by 30 to 40 per cent. above the preceding dose, and one therefore works by a geometrical progression; the method is not applicable to residual vaccines, or is so only within narrow limits. The patient cannot tolerate such increases.

The dose should be increased by some fixed amount—which was two minims in this particular series—and even then many patients required the same dose repeated once in order to establish a comfortable tolerance. It was abundantly clear that the defensive mechanism of the tissues found a greater difficulty in dealing with the toxicity of the residue.

The improvement after each dose of all the residual vaccines was greatest after the first three or four. The later doses produced a much slower improvement until it ceased altogether after the seventh dose or thereabouts. It is hoped to investigate this further at a future date. The extent of the benefit, as well as the reactions, in the "X," "S," and "A" groups is equal, and is a further proof that heat is not detrimental to the residue. The simplicity of sterilization in the autoclave compared to the usual gentle heating and subsequent testing by cultural methods is obvious.

Nature of the Toxic Substance in the Residue.

It will be apparent that the residue contains a toxic substance. Vaughan³ has shown that certain toxic bodies, apparently allied to proteins, can be obtained from bacteria, and that these bodies withstand a much higher temperature than do toxins and endotoxins. It has further been shown that some degree of immunity can be created against them, and that the local reaction when they are injected is intense. The precise origin of the toxicity may be somewhat vague, but it is evident that the residue possesses some properties which show fundamental differences from those of thermolabile toxins, and which are striking enough to justify one in separating the residual toxicity from the endotoxins.

The two cardinal features which distinguish the class are:

1. They are not rendered inert by weak solutions of oxidizing agents.
2. Their toxicity is neither destroyed nor impaired by a temperature of 120° C.

In this investigation the extent of constitutional disturbance has been taken as the standard by which to compare the toxicity of the residue with that of the thermolabile toxins. It is a reasonable physiological test, but it should be remembered that it is only a measure of the relative toxicity; it affords no indication of the relative weights of the two classes present in a culture or of the relative toxicity of the types if equal weights of each are taken.

The dose of an ordinary vaccine depends upon the amount of toxin present. The strength is stated in organisms per cubic centimetre because that is the only method of measurement available, unreliable as it is. The number of organisms is no real guide to the dose, for different strains of the same organism vary enormously in toxicity, and the amount of toxin produced by any given strain varies with the medium upon which it is grown. It is not possible to standardize the thermolabile toxin, for that substance is very unstable and becomes inert from many causes, all of a comparatively trivial nature. If the toxin is standardized when the vaccine is made, the result may be worthless in less than a month. Furthermore, the production of toxin is not an essential metabolic process, so the destruction of it does not necessarily incommode the organism at all. Antitoxins will neutralize toxins and nothing else.

It is true that a thermolabile vaccine contains bacterial protein, but only because of its accidental and unavoidable presence as part of the organism which accompanies the toxin. Its amount is small and the actual quantity quite indefinite. In effect the patient is immunized against the toxins. The destruction of the organism is left to the tissues to manage as best they can.

The rationale underlying residual vaccines rests upon a more solid basis. In these the toxic substance against which immunity is produced is the tissue protein of the organism itself, the preservation of which is essential to the life of the parasite, and the vaccine is therefore designed to strike at the primary cause of the disease; if the causal organism is destroyed its toxin can be ignored, for it will disappear whether the patient destroys it or does not.

The counting of the organisms in a residual vaccine yields information which remains accurate, the relationship of the toxic residue to the organisms being a fixed ratio, and since the residue is very stable, its toxicity does not change with age.

Finally, the therapeutic results obtained with these vaccines are more uniform. The degree of improvement is quite as great in the most promising cases, and a larger proportion of the cases benefit by the treatment. Almost all the cases in this series were drawing either a pension or sick pay, and this fact undoubtedly influenced their own estimation of the benefit received. Physical signs may be negligible or altogether absent, but it is impossible to disprove that a man still has a cough, and for this reason no case has been entered as cured. It is fairly certain that the estimates of the improvement are not unduly sanguine. This aspect of the work was realized from the start, but previous experience with the vaccine had inspired a belief that it would justify itself even under a handicap that amounted to an unfair test.

Since it has been shown that the effect of heat upon the residue is nil, the "X," "S," and "A" sections can be amalgamated into one large group in which the clinical benefit derived from residual vaccines can be demonstrated in a short table:

	Degree of Improvement.			
	Nil.	Slight.	Moderate.	Considerable.
Total number of cases treated, 52	3	9	13	27
Percentage	6	17	25	52

CLINICAL NOTES.

Chronic bronchitis as a distinct entity is especially prevalent in Manchester and Salford. Many cases date from an attack of acute bronchitis contracted on active service in France. Attacks of a spasmodic or asthmatic type are very frequent. The expectoration varies greatly in different cases, but is usually abundant and mucopurulent.

The physical signs include marked diminution of expansion and respiratory capacity, hyper-resonant percussion note, and widespread mixed râles and rhonchi. There is marked deterioration in health and capacity for employment, and as a rule there is evidence of cardiac muscle weakness.

In the presence of such changes in the physical state of the chest, and probably of permanent changes in the anatomical structure of the lungs, the influence of vaccine treatment must necessarily be limited, but several salient facts emerge from observation of a series of cases treated in this manner:

1. In most cases there is distinct improvement in the patient's general condition, in colour, vigour, and capacity for activity.
2. The sputum, which may at first increase in amount, in practically every case diminishes in quantity and loses its mucopurulent character, becoming white and less profuse.
3. The cough becomes less persistent and the attacks or paroxysms much fewer and less severe, particularly those occurring in the night and early morning.
4. A striking feature has been relief from asthmatic attacks; from the clinical point of view this is the most conspicuous effect produced by the treatment.

The clinical observers have not known the type of vaccine employed in any given case, and the results must speak for themselves.

Summary.

1. It is not possible, short of gross destruction, to detoxicate completely a suspension of pathogenic bacteria.
2. The residual toxic substance is not affected by a temperature of 120° C., it is not destroyed by weak solutions of oxidizing agents, but it is precipitated by mineral acids.
3. It is possible to remove from a suspension of organisms all the thermolabile toxins and endotoxins. Thomson's method, Dean's method, or that of the author are equally efficient.
4. It is probable that the residual toxic body is an integral part of the bacterial protoplasm.
5. Residual vaccines can be sterilized in the autoclave, so sterilization is simple and certain.
6. Residual vaccines are highly efficient therapeutic agents.
7. They retain their maximum efficiency indefinitely.
8. Most cases of uncomplicated chronic bronchitis respond to treatment by residual vaccines.

The author cannot conclude without acknowledging his indebtedness to Professor Dean for much valuable advice and constructive criticism, and to the physicians who contributed the clinical notes for their kindness in undertaking the large amount of clinical work which this investigation required.

ENCEPHALITIS LETHARGICA.

BY

G. S. HAYNES, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN, ADDENBROOK'S HOSPITAL, CAMBRIDGE.

[AFTER a brief reference to the history of the disease, and the use of the term "encephalitis lethargica," Dr. Haynes presents a classification of the symptoms given by Dr. F. M. R. Walshe in *Brain*, November, 1920. The primary division was into general symptoms and nervous symptoms. General symptoms were such signs of toxic infection as fever, eruptions, malaise, pain, headache, and gastrointestinal disturbance. The nervous symptoms were general or focal, and in each case were classified as

positive or negative, the terms being employed in the sense in which Hughlings Jackson originally used them.]

Positive symptoms are expressions of exalted function, either from irritation or loss of higher control, and negative symptoms express depression or loss of function. The general positive symptoms in lethargic encephalitis are delirium, restlessness, hallucinations, and so on; the general negative symptoms lethargy and coma. The focal positive symptoms are convulsions, involuntary movements and muscular contractions, nystagmus, rigidity, and spasm; the focal negative symptoms are paralysis.

Recognition of these two classes of symptoms—positive and negative—is very helpful, enabling us to understand that a lesion of a single area might give rise to convulsions as well as to paralysis, and that whether a clonic twitching of a muscle or weakness occurred depended not on the site, but upon the nature of the lesion.

The disease occurs at all ages, and affects both sexes equally. Three stages can be distinguished—the prodromal stage, the acute stage, and the stage of regression. The incubation period has not yet been determined. The chief prodromal symptoms, which last usually from one to seven days, but may be prolonged for three weeks, are headache, giddiness, lethargy, blurred or misty vision, and diplopia; vomiting is not common; muscular weakness frequently occurs.

The acute stage is characterized by fever (101° to 102° F.), lasting from two to five days or longer, the pulse and respiration being as a rule unaffected. The patient lies in bed semi-conscious and immobile, or with much muscular asthenia; the face is expressionless and mask-like; the limbs in many cases are rigid, and in some they remain in any position in which they are placed, as in the condition known as *flexibilitas cerea*. Usually patients can be roused from their stupor to take food or to answer questions; this they do intelligently, but in a voice often nasal and monotonous, the sentences being uttered very slowly. There may be emotional irritability, and nocturnal delirium frequently occurs. In this stage muscular twitchings and tremors may occur. There is no characteristic skin eruption, though petechiae, papules, or erythema have been observed; one case was notified as scarlet fever and another as measles. *Tache cérébrale* is readily elicited in most cases. Other symptoms are dysphagia, nausea, and constipation; the tongue is dry and coated. Retention or incontinence of urine is of frequent occurrence; the urine is concentrated, loaded with urates, and transient albuminuria is found during the febrile stage.

Paralysis of the cranial nerves is a characteristic feature the third and seventh being most commonly affected. The fundus oculi is normal. Ptosis is the usual form of third-nerve paralysis; it may be unilateral or bilateral, and slight or complete. The ciliary muscle is often involved early and paralysed longer than other ocular muscles; the pupils may be unequal; divergent or convergent squint is seen; diplopia is common. Whereas ptosis and strabismus are only transient, involvement of the movements of the eyeball may last several weeks, as may disturbance of accommodation. Facial paralysis has often been observed; it is, as a rule, bilateral, but more marked on one side than the other; the tongue and pharynx are sometimes affected and deafness has been noted.

Netter's statistics place the frequency of lethargy and ocular palsies as high as 75 per cent. of all cases, but, though with fever this is the characteristic syndrome, a large number of cases do not conform to this type; some begin with excitement and muscular twitchings or spasms, or with severe pains in the limbs; others have quiet delirium with delusions; others, again, go about with persistent headache, apathy, and lack of facial expression. In fact, as Farquhar Buzzard has pointed out, an inflammation of the encephalon can produce as many symptoms as there are functions of the brain.

Of the lethargy, which is an interesting feature of the disease, three explanations have been suggested: (1) That it is due to internal hydrocephalus, the result of occlusion or partial occlusion of the aqueduct of Sylvius by inflammatory processes in the region of the corpora quadrigemina. It is noted that sluggishness or total abolition of the pupillary reflexes frequently occurs with the lethargy, and that this combination is characteristic of tumours of the posterior end of the third ventricle. (2) That it is due to interference with the afferent paths of stimuli from the

environment, whereby stupor results. It is argued that an inflammatory lesion in the crura cerebri and optic thalami might, in addition to blocking afferent stimuli, involve the nucleus of the third nerve and give rise to the frequently observed ocular phenomena. Optic neuritis is generally absent, indicating that the lethargy is not part of a general cerebral condition, such as would be caused by hypertension, as in tumour or abscess. (3) That it is due to pressure on and inflammation of the pituitary gland. Sluggishness, with a tendency to somnolence, is a sign of hypopituitarism.

The differential diagnosis of the characteristic syndrome, with "negative" nervous signs, is to be made from the following conditions: Cerebro-spinal meningitis, in which there is commonly retraction of the head and a turbid spinal fluid containing the meningococcus; tuberculous meningitis, a somnolent form of which may occur in infancy, characterized by a dissociation of pulse and temperature and irregularity of the pulse, choked disc and choroid tubercles, with lymphocytes, albumin, and frequently tubercle bacilli in the spinal fluid; influenzal encephalitis, usually accompanied by bronchial or pulmonary signs. Cerebral syphilis is generally unaccompanied by fever; optic neuritis is frequently present, and the complement deviation test is in most cases positive. Sleeping sickness is distinguished by the presence of the trypanosome in the blood, cerebro-spinal fluid, and enlarged glands. Cerebral forms of poliomyelitis are rare; they commonly occur in the summer months; the paralyses are more generalized and are maximal when declared, whereas in lethargic encephalitis the paralyses are often slight at first but progressive. Cerebral softening, following embolism or thrombosis, or cerebral haemorrhage may simulate encephalitis, in which large areas of softening and gross haemorrhages have been found. Naked-eye post-mortem changes are not sufficient to distinguish between ordinary cerebral haemorrhage and a haemorrhagic encephalitis.

The diagnosis of cases presenting "positive" nervous signs, the excito-motor syndrome, is more difficult, especially when a history of an acute attack is lacking. Such cases are those showing involuntary movements and muscular contractions; they have been classified by Marie and Levy, who describe forms resembling chorea and paralysis agitans, and forms with rhythmic and myoclonic movements of the face, trunk, and limb muscles.

These excito-motor signs may not develop until weeks or even months after apparently complete recovery from the acute illness or after an unrecognized mild attack.

If no history of an initial acute illness be obtained the following minor symptoms may confirm the occurrence of a mild attack: onset of an illness with occipital headache and painful rigidity of the neck, accompanied by slight fever and nocturnal delirium; disturbances referable to the muscles of mastication, such as difficulty in opening the mouth fully, tremor of the jaw, chattering of the teeth, neuralgic pains in the distribution of the fifth nerve; attacks of facial spasm; excessive salivation; slowness and difficulty in articulation; a sense of constriction of the throat with difficulty in breathing or swallowing; frequent attacks of yawning or of hiccough; slight painful swelling of joints, and finally, neuralgic pains of root distribution and painful muscular cramps. One or more of these symptoms associated with slight signs of general infection indicate the occurrence of the initial infection.

The diagnosis of lethargic encephalitis can never depend upon the presence or absence of any symptom or group of symptoms. It must be determined by a consideration of the onset and course of the disease, and by the elimination of other pathological conditions which may produce similar symptoms and physical signs.

The course of the disease is very variable. Some cases are rapidly fatal, death being apparently due to paralysis of the respiratory nervous centres. The stupor may clear away in a few days or persist for several weeks, even as long as eight, and recovery may then ensue; pneumonia, many as eight, and recovery may then ensue; pneumonia, wasting and bedsores have been noted as fatal complications.

The Cerebro-spinal Fluid.

The cerebro-spinal fluid is normal in appearance; in some cases, but not in all, it is under pressure; during the first few days lymphocytosis may occur, but this is not one of

the fundamental characters of the disease, as it is of tuberculous or syphilitic meningitis, and is only of short duration; an excess of glucose is frequent but not constant, and is attributable to a certain degree of hyperglycaemia due to a lesion of the floor of the fourth ventricle.

The Blood.

The blood count is normal. Some Italian bacteriologists have isolated from broth cultures of the blood a small Gram-positive diplococcus, which was agglutinated in a dilution of 1 in 100 by the serum of the patient from whom it was isolated, and by that of other patients and of convalescents from the disease. It was not agglutinated by normal blood or by the blood of typhoid patients. Guinea-pigs inoculated with blood containing the diplococcus died on the fifth or seventh day after presenting subnormal temperature, paresis of the limbs, intense somnolence and often muscular jerking of the limbs. The brain showed punctiform haemorrhages, especially in the grey substance.

In the Government report referred to previously, James McIntosh states that, as a rule, no macroscopic changes sufficient to account for death are found post mortem. A common appearance is dilatation of the vessels, which in many instances is likely to be mistaken for haemorrhage. Histologically the changes consist of cellular infiltration of the perivascular lymphatic sheaths and of certain areas of the grey matter. The lesions are most extensive in the basal nuclei of the brain, in the upper part of the pons, particularly in the grey matter of the floor of the fourth ventricle, much less prominent in the medulla; in the cord lesions are very slight or absent.

At the annual meeting of the British Medical Association held in Cambridge last year Dr. Greenfield showed a series of lantern slides illustrating the morbid anatomy of this disease. The changes found in most early fatal cases were very diffuse, and could usually be traced from the medulla to the cortex. The most constant appearances were capillary dilatation and infiltration of the brain substance with small cells of the lymphocyte type, which were often grouped round the nerve cells as though attacking them. A comparatively common feature of the disease was infarction of the brain due to thrombosis of smaller or larger arteries.

In cases of longer standing calcareous and thrombotic changes in the vessel walls were sometimes found.

Other observers draw attention to the occurrence of gross haemorrhages chiefly in the mesencephalon.

Loewe and Strauss find that the Berkefeld filtrates of brain material, nasopharyngeal swabs, and nasal washings from cases of epidemic encephalitis produce the typical lesions of the disease in rabbits and monkeys. Spinal fluid and blood are also capable of producing the disease in this way; many of the infected animals die with the typical clinical picture of lethargic encephalitis. These observers have succeeded in cultivating a minute filtrable organism, seen as clumps of minute globular bodies with Brownian movement, young cultures of which are Gram-positive. It is obtained from the brain, nasopharyngeal mucosa, cerebro-spinal fluid, and blood of cases of the disease in man and from inoculated animals dead of the disease. The organisms thus recovered from rabbits are virulent for other rabbits.

The prognosis is not good; death occurs in from 40 to 50 per cent. of cases notified, but as probably many mild or abortive cases are not recognized and not notified the true mortality is almost certainly less.

In severe cases which recover from the acute stage, sequelae, such as impairment of the higher faculties, loss of memory, defects of speech, mental lethargy, and a general loss of intellectual tone, are common. Other sequelae are the persistence of cranial nerve palsies, paresis, and even paralysis of a limb or of limbs, athetosis, myoclonus—that is, sudden shock-like spasms of limbs, sometimes also of diaphragm and larynx. In one of my cases this myoclonus is well marked fifteen months after the onset of the disease. Symptomatic paralysis agitans may be observed. Recovery from the disease is, as a rule, gradual and tedious, chiefly on account of the great prostration and muscular weakness that are so common.

Treatment.

No specific treatment is known. Hexamine, as being the most active disinfectant of the cerebro-spinal fluid, has

been largely used; it has been given by the mouth, by the rectum, and intravenously.

Lumbar puncture, repeated at intervals, has been used with some success. The intravenous injection of salvarsan has been tried in some cases and good results reported.

The French have treated many cases by fixation abscesses; 1 or 2 c.cm. of oil of turpentine is injected subcutaneously into the middle part of the outer surface of the thigh. If no reaction occurs at the end of a few days, the injection is repeated. The resulting abscess is incised on the fifth or sixth day, or it may be aspirated. The pus is sterile. That this method is efficacious in the collection of toxic substances into one part of the body is shown by the following experiments. Toxic doses of arsenic in the form of sodium cacodylate were given to animals, and at the same time an experimental abscess was produced. The animals recovered from the arsenical poisoning, and a large proportion of the arsenic administered was recovered in the pus. A disadvantage of this form of treatment is that sometimes severe pain is caused. It has been used in cases of cerebro spinal meningitis and of influenza and pneumonia. Other remedies which have been tried in lethargic encephalitis are strychnine, horse serum, and the serum of convalescents.

During convalescence the patient should be kept at rest and free from worry; sedatives and hypnotics, such as ammonium bromide and chloralamide, being prescribed, if required, in order to limit the liability of permanent cerebral lesions occurring.

Of the thirteen cases I have seen, ten were under treatment in Addenbrooke's Hospital. Most of them were of severe type, and seven died.

The following is an example of a case of average severity:

A woman, aged 24, had been in poor health for some months; in October, 1920, her tonsils were removed, and she subsequently resumed her work. About the middle of December she became sleepy and apathetic, and was troubled by vomiting in the morning. The vision became hazy, and she had difficulty in focussing. On December 21st, she complained of frontal headache and sleepiness; she was lethargic, lying with her eyes closed, but easily roused, answering questions briskly and intelligently, and then relapsing into slumber. The temperature was 103°, the tongue thickly coated, and the reflexes very sluggish; otherwise no abnormal physical signs were observed. She was admitted to Addenbrooke's Hospital on December 22nd, and for about a fortnight remained in a drowsy condition with constant headache, and mental condition slightly confused. She had partial double ptosis, misty vision, occasional diplopia, stiffness of the masseters with inability fully to open the mouth, and paresis of the facial muscles. A recurrence of vomiting and increase of headache came on three weeks after admission, but this passed off in a few days, and the condition slowly improved, so that she was discharged after five weeks in hospital. During this time she lost nearly two stone in weight. She is now making progress, but very slowly. There is still much muscular weakness, and considerable mental depression. She is gaining 1 or 2 lb. a week in weight.

The following is an example of a very severe type of case:

A woman, aged 21, consulted a doctor on December 8th, 1920, for misty and double vision. She was sent home to bed, but grew weaker and became comatose. When first seen on December 11th she was very drowsy but could be roused to answer questions, which she did in a sleepy voice, slowly, immediately relapsing into stupor. There was some fever, a crop of red papules on the chest only, double ptosis and right external strabismus, twitching of the right ala nasi, coarse tremors, and rigidity of limbs with flexibilitas cerea.

On admission to Addenbrooke's Hospital on December 11th the coma increased, and the temperature rose; it reached 105.6° in the early morning of December 16th, when the patient died.

The result of the examination of the cerebro-spinal fluid was negative, there were no pathogenic signs; there was a little excess of sugar.

In the following case myoclonus was a prominent symptom.

A woman, aged 30, attended as an out patient on June 9th, 1920, complaining of aching in the left arm and leg, with "jumping sensations." Her illness had commenced at Christmas, 1919, with sleepiness and loss of speech lasting a fortnight. In February there was aching in the back of the neck, and later in the left side, arm, and neck. Involuntary movements of the left arm and leg now commenced and have continued ever since.

On examination the general condition was found to be good. There was tenderness about the left deltoid, the muscles of the left shoulder girdle generally were slightly wasted, and the circumference of the left calf was 1½ in. less than the right.

There was no paralysis, no ocular palsies, no sensory changes, and the reflexes were present. There were jerky involuntary movements of the affected arm and leg, occurring about every two minutes. The condition suggested hemichorea.

After treatment with arsenic and bromides with but little improvement, she was admitted. Dr. Prideaux reported as follows: "I do not think there can be any doubt that this is a genuine case of myoclonus associated with encephalitis lethargica. She is certainly not a functional case, though, as in other cases of myoclonus, the spasms are increased during emotional excitement and in fatigue. The prognosis is fairly good—that is, eventually it should clear up; cases hitherto reported have cleared up in from six months to three years."

When seen on April 2nd, 1921, fifteen months after the onset of the disease, she complained of great weakness, unsteadiness of the legs, constant twitchings of the left arm and leg, and sleeplessness. Her general condition was very poor; she was pale, weak, and thin; there was some instability on walking, and especially on turning; she was apathetic and dejected, and her face expressionless; there were regular rhythmic movements of the left arm caused by clonic spasms of the muscles of the left subscapularis, and also similar movements in the left leg synchronous with the arm, caused by spasm of the hamstrings. These movements ceased at times, and were not present during sleep.

OCULAR SYMPTOMS IN THE SLIGHTER CASES OF ENCEPHALITIS LETHARGICA.

BY

RANSOM PICKARD, C.B., C.M.G., F.R.C.S.,

FIFTH.

THERE is a special fascination in the study of borderline cases of any disease. Moreover, to obtain a complete picture of any subject it is necessary to study its fringes. The following cases are cited as bearing upon the ocular symptoms in slight cases of lethargic encephalitis; doubtless there are other groups in which symptoms other than ocular predominate, but they would not come to an oculist.

CASE I.—Diplopia: Paresis of Accommodation: Retrobulbar Neuritis: Drowsiness.

C. H., aged 32, was first seen on February 11th, 1921. His illness had started three weeks earlier with diplopia for two days, and drowsiness for a week. At the beginning there was pain in the frontal region and at the root of the nose, and "weakness of the eyes," "darkness, as if a blind were drawn down." On February 11th, vision with correction was: R. 6/6, L. 6/12; loss of accommodation was: R. +75, L. +1. There was no diplopia present. The discs were white and filled in, the edges very well defined, the branches emerging after division suddenly out of the white disc; the main vessels were not visible. This condition was more marked in the right eye.

Fields (white object) 5/300:

		Up.	In.	Down.	Out.
Right eye	...	25°	20°	20°	35°
Left eye	...	20°	25°	22°	50°

The blind spots were not charted.

The condition on May 2nd (communicated) was:—With correction: R. 5/5; L. 5/10. Near vision with same correction: R., J. 1; L. J. 1, imperfectly; there was no diplopia, the fundi was unchanged, the general condition was much better, and work was about to be started.

CASE II.—Diplopia: Paresis of Accommodation: Sleepiness: Weakness of Limbs: Retrobulbar Neuritis.

Mrs. B., aged 53. Her history was as follows: On February 27th, 1921, diplopia and sleepiness began. On March 2nd, on waking, she found that she could not walk without help because of weakness of the legs. On March 11th the condition was that she had near glasses +3.5; distance glasses +2. Her vision was R. +2 = 6/42; L. +2 = 6/9 partly. The loss of accommodation was +2.5 in each (not excessive for her age, but apparently +1 more than before the attack). The irides and fundi were normal. In regard to the fields, the right eye was contracted to from 20 to 30 deg., and the blind spot enlarged (object 5/300 white). The left eye was contracted to from 15 to 20 deg.—that is, inside the blind spot (object 5/300 white). Diplopia was crossed, and was greatest in the right half of the field; that is to say, there was paresis of the left internal rectus. The limbs were weak, but the left arm and leg were weaker than the right arm and leg. The knee jerks were equal and exaggerated. Her memory was bad. The subsequent history (communicated) was as follows: On March 29th diplopia disappeared; on April 12th vision became normal; on April 18th she was well in every respect, except for her memory, which remained very bad.

CASE III.—*Diplopia: Paresis of Accommodation: Congestion of Optic Disc: Lethargy: Delirium.*

Mr. K., aged 44 years. The history obtained was that, on February 21st, 1921, there was difficulty in reading and writing with diplopia. On February 24th he came to be tested for glasses because he found that he could read with his wife's glasses. He said he had been sleepy for the last few days. His condition was as follows: Vision: R. + 1 = 6.5 + 1.5 = J. 1 at 13 inches; L. + 1 = 6.5 partly + 1.5 = J. 1 at 13 inches. The irides were normal. The right disc of the fundi was slightly congested, the edge was sharp and there was a local swelling between the edge of the cup and the inner margin of the disc. The left disc was normal. There was diplopia, the images were uncrossed, on the same level, and separated by three degrees equal in all parts. There was paresis of divergence or spasm of convergence, but not paresis of a muscle. The subsequent history was communicated. The lethargy increased, with some delirium at night; there were involuntary tremors and general weakness, also slight paresis of one facial nerve. The temperature was 101° to 102° for five days. There was no albumin in the urine. On April 30th he had returned to business, but was still unable to read.

CASE IV.—*Diplopia: Paresis of Accommodation: Lethargy.*

Mrs. C., aged 36 years. On December 11th, 1920, she saw the tops of things double. This condition persisted for four days, but afterwards her sight was "unreliable"; she was giddy and also very shaky. She had some pain at the back of her left leg. On December 15th she was seen by her medical attendant, who found that the right pupil was larger than the left and that there was slight diplopia. On December 23rd the condition was as follows: Vision correction, R. 6/5 (6); L. 6/5 (3); the loss of accommodation R. + 1 D.; L. + 1.25 D. The irides: right pupil 3.5 mm., with very slight reaction to light and convergence; the left pupil was 2.5 mm., the reactions were normal. The diplopia was vertical, and confined to the lower right quadrant, the greatest in the lowest portion. There was paresis of the right inferior rectus. The knee-jerks were equal and exaggerated. She was pale and looked ill, but was not sleepy. Later on she became somewhat lethargic. On April 25th, 1921, she was well in all respects except that her eyes got tired after much reading, and the reactions of the right iris were sluggish.

In addition to these four cases the following may be mentioned:

CASE V.

A man, aged 52 years, seen during the later stages of recovery. There was a history of diplopia and difficulty in seeing in the earlier part of the illness. When seen there was no diplopia, and loss of accommodation was +2.5, rather full for his age. The discs were redder than normal.

A household of four adults—husband, wife, child of 5 years, and lodger—was mentioned in a letter by the medical attendant of Case III. They were all sleepy, and each adult in turn accused the others of being cross-eyed. The lodger recovered without giving up his work as a bank clerk, although he sometimes fell asleep on his ledger, and had diplopia for all distances beyond 3 ft. from his eyes. This account of his diplopia suggests paresis of an external rectus. House groups have been described, but one consisting only of light cases must be rare.

Taking a general view, it will be seen that the cases are in the main miniatures, reproductions of severe cases on a reduced scale, rather than differing from these by the omission of certain symptoms.

Collecting the symptoms together from the various cases, the following points arise:

1. *Paresis of the ciliary muscle* is usually present, but is slight in degree and slightly different in the two eyes; from 1 D. to 1.5 D. being a usual amount. As the amount of manifest hypermetropia or presbyopia varies considerably in different patients under fairly similar conditions, it is not easy to state definitely the amount of paresis present; but in these cases the histories were fairly conclusive that there was paresis and that this was slight.

From the history it seems probable that the loss of accommodation was greatest very shortly after the onset, as was apparently the case with the diplopia, but no opportunity presented itself to verify this, for no case was seen earlier than the third day of the illness.

2. *Paresis of the iris* occurred in one eye of one case; it was of medium severity.

3. *Diplopia*.—This occurred in all the four cases given in detail, as well as in the five more casually mentioned. Three still had it when seen. Two of them had paresis of one muscle served by a branch of the third nerve, but Case II showed a relative convergence not due to paresis of a muscle, for it was equal in all positions. It is better to assume that the convergence was really due to weakened divergence than to spasm of convergence. The onset of

diplopia was sudden, but it became less severe after a few days, so that Case I thought it had gone when she visited me, though this was not so. When examined there was no obvious limitation of movement in the three cases; it required examination by a light and a red glass to demonstrate it, so that this symptom was in miniature.

4. *Optic Neuritis*.—In Case II it was distinctly retrobulbar, with diminished central vision and field and enlarged blind spot. In Case I it is mainly retrobulbar, but has come forward to the disc. But there is no projection above the surface, merely a filling up of the cup, the whole disc being white. The appearance of the vessels in the right eye as they emerged from this was quite unusual, as if they suddenly appeared out of plaster-of-Paris. Case III had a slight swelling in one part of the disc. Unfortunately the fields were not taken in this case. Case V had hyperaemia of the discs. His central vision was normal; circumstances prevented the taking of his fields. Thus, in these few cases, two had definite retrobulbar optic neuritis, and there was a suspicion that Case III and Case V had a slight degree of optic neuritis. As optic neuritis has not often been recorded, it may be accidental that so large a proportion of these present cases had it, as may happen with any special symptom in a small series; but it may be that this symptom is commoner than has been suspected, the state of the patients preventing the detailed examination necessary to establish the diagnosis of retrobulbar neuritis. Or perhaps optic neuritis may be frequent in the type of this disease existing in Devon. The few cases of optic neuritis recorded in France are summarized in *Archives d'Ophthalmologie*, 1920, pp. 423 and 429.

In regard to the geographical incidence, three of these cases occurred in Exeter; the remainder in North Devon. That these cases have come under the notice of an oculist raises the suspicion that there may be others, and that slight cases of this disease may be commoner than is at present thought.

It must be pointed out that the dominant symptoms in this group of cases—paresis of accommodation, diplopia, and sleepiness—are easy to recognize. To test the accommodation exactly may require special apparatus, but if a patient has difficulty in reading come on in two or three days, and this is associated with the other two symptoms, the practitioner will not go far wrong in assuming weakness of accommodation, and in establishing a *prima facie* case for encephalitis lethargica, notwithstanding the pitfalls which surround the subject.

A NOTE ON NEW GROWTH AND A REDUCING SUBSTANCE IN THE BLOOD.

BY

A. S. LEYTON, M.D., AND H. G. LEYTON, M.D.,
CAMBRIDGE.

THE theory that a factor was present in the blood which favoured the growth of certain bacteria was at one time commonly held, and was the basis of the old idea of a "diathesis," but when Ehrlich introduced his theories of immunity the older beliefs were mostly discarded and attempts to explain the incidence of disease have been greatly influenced by his teaching.

In common with several other pathologists, however, we have often felt that applications of Ehrlich's theory were limited and did not explain many of the phenomena of disease, and, while searching for further light on these problems of immunity, we tried at one time the effect of transplanting in succession each of the endocrine glands to see if any one of them by their secretions caused or accelerated the growth of tumours, and special interest attaches now to the fact that the only one that appeared to affect the growth of inoculated sarcoma in rats was the parotid.

The bacteria with filtrable spores which can be isolated from tumours have formed the subject of communications elsewhere. Finding that this class of bacteria only thrive well on media containing sugar, we examined the blood-sugar content of patients suffering from malignant disease and found the reducing substances invariably increased. (The picric acid method was used for testing the blood, hence we do not suggest that the figures given represent

only sugar, since other reducing substances may be included). Further, in most of the cases which have been under observation for any length of time a definite excretion of sugar in the urine (as tested by Nylander's fluid) has appeared from time to time. So consistent have been the results that we have recently felt able to rely on this test to differentiate between simple and malignant cases. For example:

1. A fluctuating swelling in the neck, possibly inflammatory, showed reducing substance 0.34 per cent., and proved to be sarcoma.

2. A case with long-continued gastric symptoms, possibly malignant, gave a normal sugar content, and on laparotomy showed only simple ulceration.

3. Two cases diagnosed as tubercle of the lung gave reducing substances 0.24 per cent. and 0.32 per cent. respectively. Both proved to be malignant, whereas other cases of phthisis gave a normal result.

4. A case of acute pain in the pelvis, without obvious cause, gave reducing substance 0.29 per cent., and *post mortem* an annular carcinoma of the rectum was found.

We do not wish at this stage to enter into any discussion as to the relations of the high percentage of reducing substance as cause, effect, or concomitant, but merely to relate that through finding it we were led to try the experiment of feeding rats on sugar after they had been injected with a bacillus with filtrable spores isolated from a case of human sarcoma. This sarcoma was of the melanotic type, but the pigment was scanty.

Injections were made into the tails of eight rats. Three of the animals were large enough for the emulsion to be injected into the tail vein, but in the five smaller rats the injection was subcutaneous. All external evidence of the injection had disappeared in a week, but after five weeks a nodule the size of a split pea was found at the point of injection in one of the small rats. This proved to be mainly a spindle celled growth with a few giant cells, but some of the cells contained pigment.

One of the larger rats died after six weeks and showed extensive growths in both lungs. Microscopically large areas of necrosis were seen with a margin of cells some of which contained pigment. The original sporing bacillus was regained from this growth.

Two large rats remaining alive at the end of two months were killed and found to have nodules of growth in the lungs; one also had a primary nodule in the tail.

Six rats inoculated with the same culture, but not fed on sugar, showed no evidence of growth locally or in the lungs after three months. Six other rats fed on sugar, but not inoculated with bacteria, likewise remained healthy.

In view of the interest of the subject and the fact that rats are so difficult for us to obtain, we shall be pleased to supply a subculture of this bacillus to any cancer research institute that may care to repeat our experiments on a larger scale, and we should like to suggest to those working with simple inoculable overgrowths that they try the effect of feeding the inoculated animals on sugar.

A grant toward the expenses of this investigation was received from the Science Committee of the British Medical Association.

THE PATH OF TOXINS TO THE CENTRAL NERVOUS SYSTEM.

BY

MARTIN BUTTON, F.R.C.S. EDIN.,

RYE, SUSSEX.

The statement that the infection of the central nervous system probably takes place from the mucosa of the nasopharynx is frequently made, and an examination of the possible routes of such an agent, toxin or whatever it may be, would appear to be of interest as affording a possible explanation of the sequence of phenomena commonly observed.

Two possible routes present themselves: (a) By the blood stream, either directly or after lymphatic absorption; (b) along the nerves. A consideration of the facts would seem to indicate that both routes are made use of.

In the condition *encephalitis lethargica* we might suppose the toxin to work its way up the motor fibrillae of the facial nerve.

The path through the cribriform plate—in spite of the fact that the nasal lymphatics have been injected from the subdural space, and the short route offered by the nasal nerves as far as the meninges and olfactory nerves through

the meninges—is negatived by the fact that a toxin arriving in the anterior cerebral fossa could hardly manifest itself first by a lesion of nuclei in the tegmental region of the pons.

The facial nerve, supplying the buccinator and labial muscles in relation to the oral cavity, and probably the levator palati and musculus uvulae (lesser palatine branch of sphenopalatine ganglion, via vidian, and great superficial petrosal), in relation to the nasopharynx, could afford a mode of entrance. In the substance of the pons the ascending portion is in the closest relationship with the medial longitudinal bundle, and in all probability contributes fibres to that bundle. In addition it embraces the nucleus of the sixth nerve, in much the same manner that the loop end of a hairpin, bent on the flat, might hold a pea in its concavity.

The nucleus most intimately related to the medial longitudinal bundle is the oculo-motor, the cells of which are indeed divided by that bundle into several collections, which have been supposed to preside over separate orbital muscles. Whether the fibres for the orbicularis palpebrarum arise from the oculo-motor and descend to the facial in this bundle, as was supposed by Mendel, or whether they arise in a superior part of the facial nucleus, it is not difficult to believe that the most intimate connexion between the latter nucleus and the third is with that part of the third which presides over the levator palpebrae superioris. The trochlear and abducent nuclei are also, of course, closely placed to the same bundle.

What, then, are the symptoms we might expect from a toxin ascending by way of the facial fibrillae and medial longitudinal bundle? They are facial paralysis, ptosis, abducent or other ocular paralysis. In fact, the localizing signs commonly found in *encephalitis lethargica*.

MacNalty has suggested¹ that the stupor in this condition is occasioned by the cutting off of the afferent sensory stimuli, by involvement of the medial lemniscus, owing to its proximity to these medial somatic nuclei in the tegmental region.

I would submit that, in the region of the third nucleus, the medial lemniscus is pushed some distance laterally by the nucleus ruber; also that the lateral lemniscus, conveying auditory impressions, would not be involved; and that the lesions, though bilateral, are usually asymmetrical, so that one half of the sensory tract would probably be but slightly damaged. Therefore, one could hardly suppose that the afferent stimuli could be so entirely cut off as to produce the degree of lethargy observed. In fact, the type seen more approximates to that produced by drugs.

It would seem easier to explain it on the assumption that it was the general effect on the cerebrum of the toxin absorbed by the blood stream. There could hardly be doubt that toxin so absorbed would reach the cerebrum far more rapidly than it could travel up the nerves; but that it would be diluted by the total amount of blood in the circulation, come in contact with a greater amount of antibody, and would be supplied in equal amount to all the body cells. To suppose that, distributed in this way, it could pick out individual cranial nuclei would necessitate the assumption of a special affinity of certain motor cells for a particular toxin, and that such affinity was not possessed by other motor cells serially homologous and structurally identical—a hypothesis which does not commend itself.

Group 1, therefore, in which we have lethargy and asthenia but no localizing signs, might be supposed to be caused by absorption from the blood stream, in which death or recovery takes place before sufficient toxin has ascended by the nerve paths to cause such signs. The succeeding groups are those in which we have the effects of both in varying degrees.

The twelfth nucleus may be affected either by spread along its own fibrillae or from its connexion with the medial longitudinal bundle. Professor Marinresco, in the report quoted, expresses the opinion that the toxin travels by the way of the nerves. I have merely endeavoured to find an anatomical explanation for the sequence of events:

If we apply this hypothesis to the conditions met with in diphtheria, we have the causative organism living, and pouring out its toxin, on the walls of the pharynx and larynx, separated by a devitalized mucosa from muscles innervated by the cerebral part of the accessory (by way of branches of the vagus to the pharyngeal plexus). Toxins ascending along the fibrillae of these nerves would

be conducted to the nucleus ambiguus, which also contributes to the vagus motor fibres for the heart. This would explain the association of dysphagia, and regurgitation of food through the nose (paralysis of the palatopharyngei), with cardiac disturbance—an association commonly met with in post-diphtherial paralysis.

I saw an interesting example of the association of these nerve paths in a case of paroxysmal tachycardia. The patient, in the early stages, was sometimes able to cut short the attack by the act of swallowing—a reflex action in which the nucleus ambiguus would be predominantly concerned.

Turning to the problem presented by tetanus, we find two points in which there is a contrast with the conditions previously discussed. In the first place, the effect of this toxin upon the motor cells, if indeed its effect be upon those cells, is the reverse of paralysis; it produces increased excitability with increased output. This phenomenon is more readily interpreted as due to interference with the inhibition normally imposed upon external stimuli reaching the motor cells from the sensory side; so that the paralysis probably occurs somewhere in the reflex arc, between the synaptic endings of the afferent nerves round the cells of their terminal nuclei and the dendrites of the motor cells.

Secondly, it would seem that the toxin does not ascend along the fibrillae; for if that were the case the muscles of the reflex arc, along which it travelled, would, it might be expected, be the first affected. Presumably, then, it makes its way beneath the sheath, and on reaching the spinal medulla may be supposed to ascend beneath the membranes. When it is remembered that the motor nucleus of the trigeminal nerve derives most of its sensory stimuli from the terminal nucleus of the trigeminal afferent fibres, alongside which it lies; and that the tractus spinalis comes to the surface in the postero-lateral area of the inferior part of the medulla oblongata, in the region known as the tuberculum cinereum of Rolando; and that a toxin ascending beneath the meninges might be conducted up that tract, reason can be seen for what is otherwise difficult to understand—namely, why trismus should be the earliest, and in mild cases the only, manifestation of a toxæmia which, when sufficiently prolonged, affects the whole motor mechanism.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF SUDDEN MONOCULAR DILATATION OF THE PUPIL.

THE notes on the following case afford a striking example of how a purview of all the facts in connexion with a case, both relevant and apparently irrelevant, may help towards establishing a diagnosis, and how a quite justifiable absence of knowledge of an apparently irrelevant factor may cause failure to make a diagnosis.

A medical practitioner recently sent me a lady who had suddenly developed complete dilatation of the left pupil, accompanied by supraorbital neuralgia, some apparent slight paresis of the upper lid, and some nasal catarrh.

The condition came on after a cold motor drive. It had caused the practitioner some alarm, and he, in my opinion quite rightly, regarded it as a case for investigation. The possibilities were many and various, and the condition might well have been the precursor of serious nerve lesion.

When I saw her every trace of abnormality had disappeared; the eye was normal in appearance and function, the musculature of the eye, extrinsic as well as intrinsic, acted normally; the nasal mucous membrane was healthy and normal. I was convinced that some mydriatic had got into the eye, but there was no history of any "drops" of any kind having been used. I was not satisfied, and after an examination I elicited the fact that she had a sprained knee, that she had consulted another medical practitioner about this in another town, and that she had been given a liniment to rub the knee. She did

not know what the liniment was, but said that it contained "ammonia." The practitioner who sent her to me was not aware of this condition of the knee.

She told me that she had the prescription at home, and I asked her to go home and to telephone to me if it contained the word "belladonna." She rang me up in half an hour. The prescription contained belladonna, and the case was now clear. Unquestionably she had conveyed some of the liniment into her eye.

The case was not one in which I consider that I am entitled to credit, nor the practitioner who sent her to me to discredit; but I learnt a lesson and I pass it on as possibly being of value to others.

The accompanying supraorbital neuralgia, which had evidently not been severe, may have been due to the action of light (it was bright weather) on the relatively unprotected retina, and I have no doubt that the drooping of the eyelid was due to the unconscious lowering of the lid to shut off excessive light. I met the lady a few days later; there had been no further trouble.

Senior Honorary Ophthalmic Surgeon,
York County Hospital.

THE FORMOL-GEL REACTION IN SYPHILIS.

It has been said that "the performance of the Wassermann test involves one of the most complicated methods that have been applied to diagnosis in medicine,"¹ and many laboratory workers must have hoped that some day a simpler and more direct method of diagnosing syphilis would be found.

The formol-gel reaction recently discovered by Gaté and Papacostas² gives promise of reducing the diagnosis of syphilis to a degree of simplicity altogether unexpected. The method is as follows:

One cubic centimetre of the serum to be tested is placed in test tube, two drops of formalin (40 per cent. formaldehyde) added and the tube is shaken to mix the contents. After standing at room temperature for twenty-four to thirty hours the tubes are examined and the results read. A positive is found to have coagulated into a firm jelly, while a negative serum remains fluid. Gaté and Papacostas found that, in series of over 400 serums examined, the results corresponded with Wassermann results in 85 per cent. of cases.

I have had opportunity so far of testing only a small number of serums by this method, and the results are given in the following table.

	Formol-gel.		Wassermann.	Condition of Serum.
	Fresh Serum.	Heated Serum.		
1		+	++	Jellied.
2		±	++	Semi-liquid.
3	++		++	Firm jelly; tube can be inverted.
4	—		—	Liquid.
5	—		—	Liquid.
6	—		—	Liquid.
7	—		—	Liquid.
8	±		±	Semi-liquid.
9		—	—	Liquid.
10		—	—	Liquid.
11		—	—	Liquid.
12	++	++	++	Firm jelly; tube can be inverted.
13	—	—	—	Liquid.
14	—	—	—	Liquid.
15	—	—	—	Liquid.
16	—	—	—	Liquid.
17	++	++	++	Firm jelly; tube can be inverted.
18	—	—	—	Liquid.
19	—	—	—	Liquid.
20	—	—	—	Liquid.
21	—	—	—	Liquid.
22	—	—	—	Liquid.
23	—	—	—	Liquid.

The following notes have been made during the tests:

1. The test tubes employed should be of the same internal diameter, so that the results may be strictly comparable.
2. A diameter of half an inch has been found the most suitable for use with 1 c.cm. of serum.
3. The amount of serum for a tube of this diameter should not be less than 1 c.cm. If less than this amount is used the result is obscured by capillary attraction.
4. In the case of a strongly positive serum there is definite coagulation into a firm jelly, which remains unbroken when the tube is completely inverted or even roughly handled—example, thrown upon a table.

¹ Med. Rev. Com. Spec. Report, Series No. 21.
² C. R. Soc. Biologie, November 20th, 1920.

5. A negative serum remains quite liquid, and "runs" when the tube is tilted.

6. In serums intermediate between strong positive and negative the reaction is less definite, but, generally speaking, the degree of coagulation appears to correspond to the degree of positivity or otherwise.

7. Coagulation, when present, tends to become more marked the longer the tubes are allowed to stand—for example, a tube that was read as + after thirty hours became a + after standing for nine days; this fact might be made use of in determining the finer grades of positive and negative.

It would be premature to form any definite conclusions on such a small series of tests, but the results obtained are sufficiently striking to show the potentialities of the method, and to give rise to the hope that this rival of the Wassermann test may lead to a simple and reliable method of diagnosing syphilis.

District Laboratory, Shorncliffe. Major R. A. M.C.

Reports of Societies.

THE LARYNGOLOGICAL SUMMER MEETING.

The Section of Laryngology of the Royal Society of Medicine held a highly successful summer meeting at the House of the Royal Society of Medicine on Thursday, June 2nd, and Friday, June 3rd, 1921. The President, Dr. JOHNSON HORNE, was in the chair, and there was a very satisfactory attendance, a large number of the Scottish and provincial members of the Section being present, undeterred by the difficulties of travel at the present time, in addition to a number of distinguished foreign and colonial visitors.

The meeting was opened on Thursday afternoon by the President, and Mr. MARK HOVELL thereafter read a paper on the indications for and against complete tonsillectomy as a routine operation, which was followed by an interesting discussion. Mr. Mark Hovell held that enucleation of the tonsils for enlargement was unjustifiable, and, although he was supported by Professor BURGER of Amsterdam, who considered that tonsillectomy in children was better than tonsillotomy because it did not require anaesthesia, yet the other speakers were practically unanimous in favour of tonsillectomy as against tonsillotomy. Mr. ROSE, although he disagreed with the idea of leaving tonsillar tissue behind, thought the scarring after the complete operation was a great disadvantage, especially to singers; Mr. FAULDER, on the other hand, considered that singers were worse off with septic tonsils than with scars. Sir WILLIAM MULLIGAN, who thought the allegation as to scarring exaggerated, was of opinion that the complete operation was absolutely necessary, and Mr. STUART LOW agreed that if the tonsil was diseased it ought to be removed. Mr. HOLT DRIGGLE stated that he had found that many tonsils which could not be diagnosed as such clinically were in fact tuberculous. Mr. O'MALLEY considered that the fear of haemorrhage ought not to weigh against the operation of tonsillectomy, as he had found that the number of cases published of haemorrhage was greater in the period when tonsillotomy was practised than in the tonsillectomy period of the last eleven or twelve years. Mr. HERBERT TILLEY said that he had passed through all the stages and he now enucleated tonsils by dissection only.

Mr. WALTER HOWARTH described the operation he practised on the frontal sinus. In the discussion which followed on the relative value of the external and the intranasal operations on the frontal sinus the merits of Mr. Howarth's contribution were acknowledged. Sir STCLAIR THOMSON, in a paper on the usual site of origin of intrinsic cancer of the larynx, said that his experience of fifty laryngo-fissures now led him to believe, contrary to his former opinion, that the usual site was the anterior and middle thirds of the vocal cords. The paper was illustrated by drawings and specimens shown on the epidiascope.

In the morning session next day the papers were mainly of technical interest. Dr. LOGAN TURNER opened with a paper on paralysis of the vocal cords in cases of malignant tumours of the mamma, and Sir WILLIAM MULLIGAN followed with an exposition of his methods of practising diathermy in inoperable pharyngeal and epiglottic malignancy. Dr. IRWIN MOORE's paper on eversion of the sacculus laryngis, the so-called prolapse of the

ventricle, started an animated discussion, which, however, did not obscure his thesis that the so-called prolapse was in reality an eversion of the caecal appendix called the sacculus.

Mr. HOBDAV then read an interesting contribution on the results of over 2,000 cases of vocal cord paralysis in horses treated by the stripping of Morgagni's ventricle. Mr. Hobday practised this operation for the relief of roaring and whistling horses, and he suggested that it might be useful in the treatment of bilateral paralysis in man for which at present tracheotomy was all that could be done. In the discussion that followed, however, it was remarked that the conditions in man which gave rise to bilateral paralysis were usually of such a serious and advanced nature that it was doubtful if Mr. Hobday's operation could be satisfactorily performed, while Mr. VLASTO pointed out additional difficulties in technique to which the slight anatomical differences gave rise. Mr. TILLEY probably expressed the opinion of the meeting when he said that there were certain comparatively rare conditions in which the operation might well be tried.

The last paper in the morning session was by Mr. SYME, on bronchoscopy in the treatment of asthma; in a series of 23 cases he had had in 12 alleviation of the symptoms after the application of a 10 per cent. solution of silver nitrate to the bronchi by the aid of the bronchoscope. A subsequent speaker stated that the passing of the bronchoscope into each lung without any application had been of benefit in asthma, but in his reply Mr. Syme stated that he had done so, and had also used other applications, without the benefit which silver nitrate had given.

In the afternoon a number of demonstrations were given by Dr. MONTON on some recent developments in x-ray treatment for laryngeal cases; by Dr. MCLELLY on the technique of blood transfusion; and by Mr. LAYTON, who demonstrated some specimens from the Onodi collection. The afternoon session was followed by the ordinary clinical meeting of the Section of Laryngology, when Dr. DOUGLAS GUTHRIE showed a specimen of a collar stud which in the oesophagus of an infant had caused osteomyelitis and death. Dr. CUMLEY demonstrated new tracheotomy instruments; Sir STCLAIR THOMSON showed a number of cases of tuberculosis of the larynx in which good results had followed treatment with the galvanic cautery; and Dr. FREDERICK SPICER showed a case of laryngocoele after operation, which he had previously shown last year and which gave rise to considerable discussion. Other cases were shown by Mr. JEFFERSON FAULDER, Dr. DAN MCKENZIE, Mr. O'MALLEY, and Dr. ELEANOR LOWRY. In the evening a very successful dinner was held at the Trocadero Restaurant, at which Professor Burger of Amsterdam, Sir Frank Colyer, Sir Charles Gordon-Watson and other guests were present, and on Saturday morning a number of special operations were performed at University College Hospital by Mr. Herbert Tilley and others.

An interesting ceremony in connexion with the Summer Meeting took place on Sunday, June 5th, when a number of representative laryngologists met at Wargrave to place a laurel wreath on the grave of Sir Morell Mackenzie in the churchyard there. The members of the Section and other guests were invited to lunch by Dr. Irwin Moore, who lives at the house in Wargrave which was formerly Sir Morell Mackenzie's, and thereafter they walked in procession to the churchyard, where they were met by the vicar, who held a short memorial service. The laurel wreath was placed on the grave by Mr. Mark Hovell and Dr. Donelan, both old pupils and house-surgeons of Mackenzie's, and Mr. Mark Hovell made an oration on the qualities of Sir Morell Mackenzie as a man, and told of the long battle against ill health which the great laryngologist had had, of his innumerable acts of private charity, and of his many achievements. Sir STCLAIR THOMSON then spoke of him from the professional point of view as the "father of laryngology," and said that, following Lamb's advice, whenever a new book on laryngology was published he read Mackenzie's old book, and there found many of the so-called new ideas. Sir JAMES DUNDAS GRANT also spoke, referring to the fact that a commemorative tablet had been placed on the house at Leytonstone where Morell Mackenzie was born. The villagers of Wargrave crowded into the old churchyard, and the village choir led the singing of appropriate hymns. In the background were the two surviving daughters of Morell Mackenzie, and

Mr. Gustave Garcia, son of the great Manuel Garcia, stood near. Round the grave of the pioneer of the science who had been dead for nearly thirty years were grouped, with bowed heads, most of those whose names are best known in laryngology to-day, and there, in the brilliant sunshine of the summer afternoon, the touching little ceremony ended.

CARDIAC MASSAGE.

At a meeting of the Section of Surgery of the Royal Society of Medicine, held on June 1st, Dr. A. GOODMAN LEVY read a communication on cardiac massage. He claimed that consistently successful results—at least in the case of cats, though not in the case of dogs—had been obtained in the laboratory, and therefore the results obtained when dealing with the human subject ought to be much better than they were, even allowing for the fact that the completeness of laboratory control was not possible. Successes were recorded, but failures were so many as almost to bring the method into disfavour. The purpose of cardiac massage was to create an artificial circulation; the procedure employed was purely mechanical, and must be combined with an efficient method of artificial respiration. Success was rarely possible without this accompaniment, and to justify cardiac massage both the surgeon and the anaesthetist should be thorough in all that they did. The term "massage" was inappropriate; it was not a massage of the muscular tissues of the heart which was intended, but an effective rhythmical compression of the heart, including the expulsion of the contents of both ventricles, for he had not found his attempts successful unless the right ventricle as well as the left received attention. He discussed the various methods of access; in nearly all the successful cases pressure was applied under the diaphragm, not involving the incision of the diaphragm, as in the transdiaphragmatic method, but success had been claimed for the thoracic route also. There was no question at all as to the adequacy of massage to restore the beat of a heart overdosed with chloroform, but syncope from primary cardiac failure introduced other considerations. Not more than two minutes should be allowed for the chance of spontaneous recovery with primary cardiac syncope, and after that time massage should proceed without hesitation. A point of some importance in the procedure was intermittency. If the massage was not successful after ten minutes, the action should be intermitted by intervals of rest, from fifteen seconds increasing to forty-five seconds, and it would often be found that during the rest period or on resumption of massage following it the heart recovered. A table of times shown by Dr. Levy indicated that the duration of massage before recovery occurred was very variable, and apparently had no relation to the interval between the moment of syncope and the commencement of massage.

The lateness of the hour ruled out almost all discussion upon Dr. Levy's paper, but there was time for one member of the Section to suggest that the good results were solely due to the artificial respiration given concurrently with the massage, and would be forthcoming just the same if the massage were omitted.

THE Société Belge de Neurologie et de Psychiatrie recently celebrated its twenty-fifth anniversary at Brussels, when the subject for discussion introduced by Drs. Ley and Alexander was the psychological and anatomical study of senility.

THE forty-first annual meeting of the Ontario Medical Association was held at Niagara Falls, from May 31st to June 3rd, and the Canadian Society of Anaesthetists, the Interstate Association of Anaesthetists of America, the Ontario Radiological Society, the Canadian Radiological Society, and the Ontario Hospitals Association held meetings concurrently. Besides addresses on surgery by Dr. Starr Judd, and on medicine by Dr. Frank Billings, there were sectional meetings and discussions on medicine, surgery, obstetrics and gynaecology, radiology, ophthalmology, and oto-rhino-laryngology, and a scientific exhibit with special demonstrations. There were three dinners, at one of which the President of the Association, Dr. Eburner Mullin, spoke, and at another the President of the Trades and Labour Congress of Canada, while many other social attractions were arranged.

Rebels.

OPERATIVE SURGERY.

WE are glad to welcome the third edition of the manual of *Operative Surgery*,¹ by THOMSON and MILES, which is a companion volume to the *Manual of Surgery* by the same authors. Any disappointment with which the surgical profession received the first edition has been completely dissipated by the admirable production now before us; its scope is considerably wider than that of the first edition, and we are sure that the volume will appeal to all classes of the profession not only on its own merits but also from the fact that it may be regarded as thoroughly representative of the surgery of the Edinburgh school. The book is divided into two sections—general and regional; the former deals with surgical technique, anaesthetics, and general considerations as to amputations and operations on blood vessels, nerves, bones, and joints; the latter part is concerned with operations on the various regions. It is significant that in the chapter on anaesthetics the description of the action and mode of administration of ether takes precedence of that of chloroform, and occupies five times the number of pages. The general discussion on the various anaesthetic substances is very fair-minded, the claims of each being presented fully and of the whole, a preference for open ether. . . . of the book may be realized from the introduction in the chapter dealing with transfusion of blood, of Moss's classification of blood groups. Following the plan adopted in the first edition, each chapter in the regional part of the book is preceded by a succinct anatomical description of the parts to be dealt with. This anatomical introduction is apt by some authors to be overdone, but any reader of this work will agree that the interest of the descriptions of the operations is greatly enhanced by the short anatomical sketch of the parts involved. We note with a certain measure of regret that in these anatomical descriptions the new nomenclature seems to be generally employed, though in each instance the old nomenclature appears alongside. Illustrations are plentiful but by no means redundant, and they are of high quality. A few errors in the letterpress have crept in (page 37 line 37, page 432 line 13, page 529 line 10), while the clamp shown in the picture illustrating Mitchell's operation for piles is not Mitchell's clamp but an ordinary transverse serrated forceps. These are, however, small blemishes in a most excellent work, and are indicated simply for the purposes of alteration in the next edition. The book is one which can be very heartily commended to practitioners, operating surgeons, and men preparing for a fellowship examination; its production reflects the highest credit not only on the authors but also on the publishers.

WE were able to welcome the first English edition of SCHMIEDEN'S *Operative Surgery*² with commendatory words. The second edition is somewhat enlarged, and apparently an effort has been made to make the work less of an operative surgery class-room book and more like a volume of value to the practitioner and the surgeon. To a very great extent, however, the book remains more suitable for the student taking a course of operative surgery than for the practising surgeon. The illustrations, though well drawn, are more helpful when operating on the cadaver than on the living subject. The book appears to be popular in Germany, as six editions have already appeared. The observations in the translator's introduction are, on the whole, somewhat trite, and one has difficulty in comprehending the meaning he desires to be attached to two diagrams consisting of a series of seven black dots labelled stomach, heart, lung, etc., connected together in one instance by a dotted line and in the other by a plain

¹ *Operative Surgery*. A companion volume to a *Manual of Surgery*. Vols. I and II. By Alexis Thomson, F.R.C.S. (Edin.), and Alexander Miles, F.R.C.S. (Edin.). Third edition. London: Henry Frowde, Hodder and Stoughton. 1920. (Cr. 8vo, pp. 637; 279 figures, 16s. net.)
² *The Course of Operative Surgery. A Handbook for Practitioners and Students*. By Professor Dr. Victor Schmieden, University of Halle, and . . . Ch.B. (Glasg.) lately Demonstrator of . . . of Glasgow. Second enlarged English edition. 1920. London: Baillière, Tindall, and Cox. (Roy. 8vo, pp. xx+350; 4s. 6d. net.)

line. The translator describes two cases in which mistaken diagnosis was made, and remarks that "a more scientific outlook is to regard the body as reacting as one whole to disease or infection or external changes, and to interpret particular symptoms . . . not as pointing to any one organ as the cause of the particular illness . . . but rather as the localized signs, interruptions, diminutions and exacerbations of the general condition." This, of course, is what we all know, and is constantly before the mind of every teacher. On the whole we do not think that this book approaches, in excellence or usefulness to the practitioner and student, many books on operative surgery published by British authors.

A SERUM TEST IN SYPHILIS.

Dr. ARTHUR VERNES's *Atlas de Syphilimétrie*¹ contains much that is of interest to the syphilologist and much that will require careful investigation before a definite opinion can be given of its value. The author has elaborated a special serum test for syphilis, which he claims is not only useful for diagnostic purposes, but is especially valuable as a means of controlling treatment and of verifying cure. The test is a very elaborate one, and it is impossible to furnish a complete description. Briefly stated, the basis of it is as follows: When a substance which the author calls "perethynol" (a fluid containing an infinite number of ultra-microscopic granules in suspension) is added to any human serum flocculation takes place—that is, the granules congregate into masses, microscopic at first, but later becoming visible to the naked eye. Perethynol is an ethylene perchloride and alcohol extract of horse's heart. In syphilis this flocculation is more marked and is proportional to the intensity of the infection. A single test is of little value, but by making a series of tests a curve may be formed, the curve of a syphilitic being very different from that of a normal person. The author has discovered that pig's serum is "antiflocculent," opposing the formation of granules. On the other hand, pig's serum is haemolytic for sheep's red corpuscles. What is of interest is the fact that in exercising the antiflocculent property pig's serum loses its haemolytic action. The application of this is evident. Perethynol, human serum, pig's serum, and, later, sheep's corpuscles, are added together. In proportion as the pig's serum prevents flocculation it loses its power of haemolyzing the corpuscles, so that the latter are completely, partially, or not at all haemolyzed. The degree of haemolysis is found to correspond to the intensity of the syphilis, being complete with a normal serum and almost nil with a powerful syphilitic one.

The results of a series of tests are recorded graphically. Injections of arsenical preparations are also found to exercise an action on the flocculating power of the blood, and Dr. Vernes claims that his reaction enables treatment to be controlled in a completely satisfactory manner.

It is difficult at the present moment to estimate the value of Dr. Vernes's observations. Up to now they have only been tested in a few laboratories in England, and much work will have to be done on the subject. The technique of the reaction appears to be somewhat difficult, and requires the services of a highly skilled pathologist. Dr. Vernes's *Atlas* is written in a lucid style, and is most excellently illustrated by means of numerous charts.

BACTERIOLOGY.

The seventh edition of Professor HEWLETT's well-known *Manual of Bacteriology*,² while preserving the general features of former editions, has been revised and brought up to date, so as to include reference to, amongst other things, the serological types of the pneumococcus, Holman's classification of streptococci and infections by paratyphoid C. The section dealing with spirochaetal infections contains an account of Noguchi's recent work on yellow fever, and some of the other sections have been revised where necessary. A full description is now given of the technique of Fildes and McIntosh for carrying out the Wassermann reaction. When a subject is developing so rapidly and on

so wide a front as bacteriology, the task of writing a satisfactory textbook is particularly difficult, since an edition is no sooner published than inevitably it begins to grow rapidly out of date.

Professor Hewlett's volume is the work of a teacher of great experience; the printing and illustrations are excellent; the subject matter is well set out and the diction is extremely clear and comprehensive, so that the book is, perhaps, the most readable of all the bacteriological textbooks in English. These characters have justly gained for it a wide popularity. The following criticisms are offered in a constructive spirit. The book now runs to over 800 pages—surely some compression could be effected without materially reducing its value? On general grounds it seems a pity to label Welch's bacillus by its later Continental name of *perfringens*. While Wassermann's reaction is fully dealt with, we see no reference to the far simpler Sachs-Georgi reaction, which is making such rapid strides on the Continent as a check, if not eventually as a substitute, for the more complicated and difficult Wassermann test. Finally, we should like to see a rather more full description of the present state of knowledge concerning filtrable viruses: Lipschütz's classification of them, given in Kolle and Wassermann's *Handbuch*, is well worthy of mention in the next edition of one of the leading textbooks of bacteriology in this country.

TYPHUS FEVER IN SERBIA.

THE monograph entitled *Typhus Fever, with Particular Reference to the Serbian Epidemic*,³ by Dr. RICHARD P. STRONG and colleagues, contains a full account of the work of the American Red Cross in connexion with the suppression of the typhus epidemic in Serbia. The book is divided into four parts. The first, which is written by Dr. Strong, contains a general account of typhus fever, with particular reference to the Serbian epidemic of 1915, followed by a description of the Polish epidemic of 1916. A vivid account is given of the deplorable conditions prevailing in Serbia shortly after the arrival of the American Red Cross. "The conditions in many of the hospitals were about as bad as they well could be. There was no lavatory or bathing or toilet facilities for the patients, no clean linen or clothing for them, and no systematic disinfection of such linen or the beds. There were usually no nurses and often only a few Austrian prisoners as attendants. . . . Under such conditions the mortality was naturally great, and reached in some instances as high as 70 per cent." As a result of the establishment of an international sanitary commission, consisting of American, British, French, Russian and Serbian representatives, the country was divided into sanitary districts, to which were attached sanitary personnel, sanitary stations and hospitals, and an active antityphus campaign was carried out. The epidemic was brought, to an end by the efforts of the Serbian medical and sanitary officers and other officials and the Serbian people themselves, working with the foreign detachments. In his account of the Polish epidemic Dr. Strong declares that the antityphus campaign is not being prosecuted by the Polish Government in an energetic and satisfactory manner, and that if the world does not fight typhus in Poland it may soon have to fight it in other countries as well. The second part, which is written by Dr. SHATTUCK, is devoted to a description of his clinical observations on typhus fever in Serbia in 1915, and may be said to be the most complete account of the disease given since Marchison. Of the cases observed, 100 were studied in detail, autopsies being performed in 20 cases; 42 cases are related in full. The third, fourth and fifth parts, written by Drs. SELLARDS, ZINSSER, and HOPKINS respectively, give an account of the laboratory work carried on in Serbia. The absence of any mention in this part of the work of the Weil-Felix reaction, which plays so important a part in the laboratory diagnosis of typhus, is to be explained by the fact that in 1915 its value had not been recognized. Moreover, as Dr. Strong points out, during the severe period of the epidemic the number of patients admitted into the hospitals were so numerous that the use of any such methods would have been precluded.

¹ *Atlas de Syphilimétrie (100 Graphiques). Les Conditions Expérimentales de l'Extinction de la Syphilis.* By A. Vernes. Paris: F. Alcan. 1920. 11x7; pp. 121. Fr. 35.

² *A Manual of Bacteriology.* By R. Tanner Hewlett, M.D. F.R.C.P., D.P.H. Seventh edition. London: J. and A. Churchill. 1921. (Demy 8vo, pp. 817; 68 figures, 21 plates. 21s. net.)

³ *Typhus Fever, with Particular Reference to the Serbian Epidemic.* By R. P. Strong, M.D., G. Shattuck, M.D., H. Zinsser, M.D., J. G. Hopkins, M.D. Published by the American Red Cross at the Harvard University Press. 1920. (Imp. 8vo, pp. 273; 25 plates.)

Diagnosis from clinical manifestations was the only method possible under such circumstances.

The writers are to be congratulated upon having produced, not only a worthy memorial of the achievements of the American Red Cross, but also an important contribution to the medical history of the war.

DIABETES.

PROFESSOR MARCEL LABBÉ has collected his clinical lectures and papers contributed to various journals on the subject of diabetes mellitus into a volume.⁶ The result is a series of chapters which do not form a very coherent whole. The main point on which the author insists is the recognition of two varieties of diabetes, which he designates *le diabète sans dénutrition* and *le diabète avec dénutrition*. The distinction between the two was formerly expressed in terms of the patients' appearance, "fat diabetics" and "thin diabetics." Professor Labbé contends that the true distinguishing feature is that in the former condition it is the carbohydrate metabolism alone that is deranged, whilst in the latter the protein metabolism is involved also. The clinical description of the disease is admirable, and illustrated by full accounts of cases with painstaking analyses of intake and output. The treatment is discussed at considerable length, but it is unfortunate that this portion of the work is not brought sufficiently up to date to include any mention of Allen's observations and suggestions.

The complications of diabetes are dealt with very fully, and there is an excellent chapter on surgery in diabetics, in which special stress is laid on the choice of anaesthetics. Spinal anaesthesia is the method to be employed for preference, but if a general anaesthetic is unavoidable, ethyl chloride is recommended. It must be admitted that on the whole the book does not advance our knowledge of the causation and prevention of diabetes very far. The records of deranged functions as manifested by abnormalities in excretion are singularly full, but these records do not shed much new light. The principal value of Professor Labbé's discussion of diabetes is to emphasize the necessity for investigation of the disturbances of protein metabolism, instead of, as in the past, concentrating attention too exclusively on the fate of carbohydrates in the body.

THE ART OF DINING.

The selection of writings to be included in the series of Pilgrims' Books is being made with excellent judgement. The last volume we have seen, *The Art of High Health*,⁷ consists of extracts from WALKER'S *Original*, and a translation of Cornaro's "Sure method of attaining a long and healthful life." Cornaro was born in Venice in 1467 and died in Padua in 1566. His treatise is well known and has a distinct place in the history of dietetics; he was probably the first to use the balance in the study of that subject, and was the advocate of a low mixed diet, consisting of 12 oz. of solid food and 14 oz. of wine a day. Walker was a London stipendiary magistrate who started a weekly paper, *The Original*, the publication of which was stopped after six months, owing to the onset of what proved to be the writer's last illness. Walker's views as to health are remarkable rather for sound common sense than originality. Cornaro apostrophized "O sacred and beneficent Moderation," and Walker was for that Goddess in all things. "Anxiety and quackery," he says, "are destructive of health, but a reasonable attention is absolutely necessary." He mentions what must be a very early instance of a line of treatment now popular, relating how a physician, called to a young lady subject to dreadful fits, "found out that her teeth were in such a state as effectually to prevent mastication; he adopted the strong measure of causing all her teeth to be drawn and a fresh set put in, from which time she completely recovered." Walker's "Aristology or the Art of Dining," which forms the second part of the volume before us, shows that while on hospitable thoughts intent he was an advocate of simplicity. Sir Henry Thompson, famous during the last quarter of the nineteenth century as a medical host, had

without doubt studied Walker. Thompson had seven guests at his "octaves," and Walker wrote: "Eight I hold to be the golden number, never to be exceeded without weakening the efficacy of concentration." A dinner Walker gave at a tavern at Blackwall consisted of turtle soup with cayenne and "lemons cut in halves not in quarters," whitebait with brown bread and butter in abundance, grouse, apple fritters and jelly, ices, a good dessert, coffee and one glass of liqueur; with the soup, iced punch; with the whitebait, iced champagne; and with the grouse, claret: "I shall permit no other wines unless, perchance, a bottle or two of port if particularly wanted, as I hold variety of wines a great mistake." Such a dinner would have suited Thompson's ideas well: both he and Walker looked on dinner as an occasion for talk among guests asked, as the latter says, for some reason, "for people brought together unconnectedly had, in my opinion, better be kept separate." But Walker could be a great deal simpler than this, and would invite friends to share his dinner of herrings, hashed mutton and cranberry tart. Walker's governing idea was that, given simplicity, not necessarily divorced from elegance, the best digestives were tranquillity of mind, leisure and agreeable company. Who shall gainsay him?

NOTES ON BOOKS.

THE *Essentials of Medicine* in Lippincott's Nursing Manuals has been written by Professor C. P. EMERSON⁸ for students beginning a medical course, for nurses, and for all others interested in the care of the sick, in clear and simple language, and is copiously illustrated and provided with an ample glossary. Professor Emerson is well known as the author of a good book on *Clinical Diagnosis*, and his elementary exposition of medicine for nurses and others has the essentials of success.

Mr. GORDON SAMESON'S book, *Every Man His Own Builder*,⁹ first appeared in 1912, and the third edition is offered to the public at a time when housing is an urgent problem. The author is an architect, and his object is "to show how any man of normal bodily strength can at need build his own house without the aid of skilled labour." His book is written in plain language and every process is illustrated by explanatory sketches, and a wealth of plans and elevations, intended to ease the task of the amateur builder unversed in the technicalities of professional house designers and builders. In the present edition a table printed in red ink shows the increases in the cost of common building materials at the close of 1920 compared with the prices ruling in 1914.

The general medical reader will find Mr. F. W. RAYNES'S treatise on *Domestic Sanitary Engineering and Plumbing*¹⁰ a good deal fuller and more technical than he is likely to need for ordinary professional or household purposes; but it contains much that is of interest to students of sanitary science and those engaged in public health administration. The main subjects dealt with are indicated in the subtitle; they are domestic water supplies, pump and hydraulic ram work, hydraulics generally, sanitary work, heating by low pressure, hot water systems, and external plumbing. The book is thus intended mainly for students of domestic sanitary engineering and plumbing, and for those whose business it is to design, supervise, or carry out work in this branch of engineering. It is copiously illustrated with drawings, tables, formulae, and worked examples. Chapters VI, VII, VIII, IX, and X are those that especially concern the medical sanitarian; they give a straightforward account of modern drainage work and domestic water supplies from the standpoint of the practical engineer.

THE publication of Mr. Walter Verdon's book, *Angina Pectoris*, has been transferred to Messrs. Baillière, Tindall, and Cox, of 8, Henrietta Street, Covent Garden, W.C.2.

THE COMING OF AGE OF ORAL SEPSIS.

BY

WILLIAM HUNTER, C.B., M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE LONDON FIFTY HOSPITAL; CONSULTING
PHYSICIAN TO CHARING CROSS HOSPITAL.

ON the occasion of which an account appeared in the *JOURNAL* of May 28th, p. 787, Sir Thomas Barlow kindly mentioned my earlier studies on anaemia (1887-90) and the endeavours underlying them to ascertain causes rather than find remedies. May I refer to the following, which I recall now with interest? When, after five years, I described the results (in 1890), I received a letter from a friend saying that it was all very well to describe results of observations and experiments, but what was the practical good of them? The reply I made was: "I don't know what the practical good is, but these are the facts."

The sequel, ten years later (1900), was the practical one, whose importance is now so widely recognized, to which reference was made by Sir Thomas Barlow—namely, the recognition of "Oral Sepsis" as the greatest septic infection in medicine, and of "Oral Antisepsis" as one of the most important and simplest and easiest measures for the prevention of a widespread group of maladies affecting almost every system of the body.

So far as this great practical measure is concerned, it was infinite curiosity about a piece of pigment of no earthly interest to anyone—followed up by studies and experiments lasting fifteen years—that led me to attach importance to oral sepsis as a disease factor, now recognized to be of the greatest possible practical interest to everyone. This outcome has been the greatest satisfaction of my life.

It is of the more interest to me since, as it happens, this summer "Oral Sepsis" celebrates her coming of age—the 21st anniversary of her appearance in medical literature under her new name. She made her entry very quietly, shyly, and even apologetically, her sponsor introducing her with these words:—

"That the common condition I am now about to describe should have any possible connexion with anaemia, especially with so severe and rare a form of anaemia as the one which (alone among all diseases) bears the deadly prognostic title of 'pernicious,' was something for which I was quite unprepared. But the following are the facts."

Although of good parentage—her parents being Experimental Pathology and Clinical Medicine—she had been and still remained at the age of eleven a very delicate child. To give her courage and individuality I sought for a fitting name, and gave her the name of "Oral Sepsis" ("Oral Sepsis as a Cause of Disease," *BRITISH MEDICAL JOURNAL*, July 28th, 1900, p. 215). My object in giving this special name was definitely to emphasize the nature and importance of the part she played in connexion with ill health.

"It is not the absence of teeth, but the presence of sepsis; it is not dental defects *per se*, but chronic septic poisoning; it is not defective mastication but effective sepsis, it is not accumulation of fermenting food debris between the teeth, but the presence of virulent streptococcal sepsis in open wounds in the gums and sockets, in the teeth and bone, that underlie the ill health so frequently associated with 'bad mouths'."

The first reception she got was chilling enough. She was promptly called names—designated a "hypothesis" and a "theory"; even the play in which she was staged—that of "Medical Sepsis," as I termed it in 1904—was said not to exist. I recall, on the other hand, the encouraging note I received from an old friend and good physician, the late Dr. George Gibson of Edinburgh: "You have not only invented a new name, but a new disease." Soon, from 1902 onwards, the interest in oral sepsis grew steadily greater, and it has increased steadily ever since.

If the great subject of sepsis in medicine was a theory so also was the whole subject of surgical sepsis; if oral sepsis was a theory, so also was a fatty tumour. The only difference between the two was that no one knew anything about a fatty tumour except that it was a fact which could not be explained, was not preventable, and did no harm; whereas oral sepsis and the multiple ill effects which it produces were great facts of the first magnitude, which could be explained, and were largely preventable.

Since that time much about "oral sepsis" has appeared in medical literature, and an incalculable amount of oral sepsis has been removed, with incalculable benefit to the

world. But an incalculable amount still remains. It still holds true, as summarized in the presidential address (July, 1910) of a physician than whom no one has wider knowledge and experience—Dr. J. Mitchell Bruce:

"Its effects are so widespread, so multiple, and frequently so grave as to make us ashamed of our previous blindness to a common source of blood infection staring us in the face all these years."

But if oral sepsis as a disease factor has thus played, and still continues to play, so important a part, we have now the satisfaction that it is playing it before a big audience; and that many "antibodies" have been formed against it in every branch of medicine, representing almost every system of the body.

To sum up: the gorge created in the landscape of medical diseases by this subject of oral sepsis in the past twenty-one years is both wide and deep; the volume of muddy waters of medical sepsis which has all along been there can now be seen crashing down it visible to all eyes. The rôle of oral sepsis in its causation has received a great volume of recognition, obscured at first by the mists created by its fall, then collecting itself into a great body of facts, till in a period of ten years (1910), and still more now after twenty-one years, it can be seen pouring itself over the "rapids" in a torrent of recognition of its importance not only as a medical but as a great national concern of health.

May I add that I have watched this result with great interest, both from a clinical and a pathological point of view? From the clinical point of view, in the course of some forty years' experience, I can recall nothing so astounding as the marvellous change in health I have seen time and again caused by the removal of obvious, glaring, but continuously overlooked conditions of oral sepsis.

But great as this interest has been, it has almost, if that were possible, been exceeded by the reflection, that so far as my own experience is concerned, it was pathology, and first of all experimental pathology, that formed the basis of my original conclusions. For it was the establishment of the first research endowment in experimental pathology in the country—namely, the John Lucas Walker Studentship in the University of Cambridge—that first gave me in 1887 the opportunity to begin the studies, remote apparently from all spheres of practical interest, that have been associated, directly or indirectly, with such extraordinarily interesting, practical, and unexpected results in the arrest and prevention of disease. So far as these studies have been connected with any of these results, credit may most fittingly be given to the far sighted and beneficent purposes of those who, like the founder of that Studentship, endeavour to advance the healing art by facilitating investigations into its causation that might otherwise have been impossible.

THE SERUM DIAGNOSIS OF SYPHILIS.

PROFESSOR DREYER'S METHOD.

ON June 2nd Professor GEORGES DREYER, M.D., F.R.S., introduced by Sir ALMROTH WRIGHT, gave a lecture, in the Institute of Pathology and Research at St. Mary's Hospital, on the flocculation test for syphilis, which he has devised.

Professor DREYER began by pointing out that the Wassermann reaction, although for all practical purposes specific, was not really quantitative, so that different workers' results could not be compared numerically, and moreover it was very complicated and employed a large number of variable reagents. In attempting to do away with the necessity for the haemolytic system Herman and Perutz had used the property possessed by syphilitic serum of flocculating a saline suspension of sodium glycocholate and cholesterol. This reaction, however, had proved less sensitive than the Wassermann reaction, and also gave a fair number of false positive results. Sachs and Georgi had improved the flocculation test by using an alcoholic heart extract with cholesterol. To 0.5 c.m. of this fluid they added 1 c.m. of the serum to be tested diluted 1 in 10, incubated the tubes for two hours at 37° C., and then left them at room temperature for twenty hours before reading the results. This test also gave in the hands of most workers a certain number of false negative and false positive results.

Professor Dreyer then outlined the ideals to be aimed at in devising a test of this sort. These were: that the technique should be simple; that there should be one

variant only—namely, the serum to be tested; that the results should be expressible in definite units per cubic centimetre, whether absolute quantities (for example, cubic centimetres) or relative quantities (for example, drops) of the different reagents were used in the test; and finally, that the standard unit should be easily maintained and checked.

The Flocculation Test.

The lecturer then detailed the reagents and apparatus required for his test. These were as follows:

An alcoholic extract of calf's heart prepared in a definite and simple manner, which he described. This solution keeps perfectly for at least two years, at room temperature, in the dark.

A 1 per cent. solution of pure cholesterol in absolute alcohol.

The serum to be tested. Sterile 0.9 per cent. saline.

Agglutination tubes and stands.

Pipettes and water-baths.

An apparatus, consisting of a floating siphon, for delivering drops of saline at a definite rate.

A shaded electric light and a 6 magnification hand lens.

An essential feature of the test is the method of preparing the saline suspension of the heart-extract-cholesterol mixture, so that it is the same on all occasions and when made by different workers.

Five c.cm. of the heart extract and 0.25 c.cm. of the cholesterol solution are measured into a clean dry tube and mixed; 1 c.cm. of this mixture is placed at the bottom of a 100 c.cm. measuring cylinder. Sterile normal saline is then allowed to fall from the dropping apparatus a distance of 36 cm. on to the surface of the liquid in the cylinder at such a rate that 34 c.cm. are delivered in 4 mins. 30 secs.

Two suspensions are prepared in this manner, namely:

α. One c.cm. of the heart-cholesterol mixture into which are dropped 10.7 c.cm. of saline.

β. One c.cm. of the heart-cholesterol mixture into which are dropped 34 c.cm. of saline.

The test is then set up, using the two suspensions α and β and different dilutions of serum as shown in the following table.

No. of Tube.	Drops of Saline Solution.	Drops of Serum Diluted 1 : 1. 1 : 20.	Drops of Suspension.	Total Dilution in which the Serum Acts.
1	0	20 1 : 1	6 α suspension	1 : 1.25
2	0	10 1 : 1	15 β suspension	1 : 2.5
3	5	5 1 : 1	15 "	1 : 5.2
4	8	2 1 : 1	15 "	1 : 13.1
5	9	1 1 : 1	15 "	1 : 26.4
6	0	10 1 : 20	15 "	1 : 46
7	5	5 1 : 20	15 "	1 : 92

9	9	1 1 : 20	15 "	1 : 462

The dilutions in the last column are calculated with allowance for the difference in size of the drops of the three reagents. After the test is set up the tubes are incubated for seven hours in a water-bath at 37° C. The results must be read by artificial light—for example, an electric bulb with an opaque shade so arranged that the light falls on the tubes but not on the observer's eye.

The lecturer then described the different degrees of flocculation observable—namely, Total (t.); Standard (s.); Trace (tr.); and Nil (0) with their intermediate degrees.

"Standard" flocculation can readily be seen with the naked eye; the fine flocculi are evenly distributed, of uniform size and definitely separated from one another. "Trace" is the term applied to very fine flocculation not certainly visible to the normal eye, but readily seen with the 6x hand lens.

The result is expressed in what Professor Dreyer has called Sigma (Σ) units. The standard Σ unit is an arbitrary unit arrived at as follows: The amount of serum which when made up to 1 c.cm. with normal saline causes "standard" flocculation on being mixed with 1.5 c.cm. of a particular β suspension and kept at 37° C. for seven hours is said to contain four Σ units. To find the strength of a serum in Σ units one must multiply the dilution in which "standard" flocculation occurs by the suspension factor of the particular suspension.

Professor Dreyer then showed tables by reference to which the strength of a serum in Σ units could be computed when the "suspension factor" of the particular

suspension in use was known. He mentioned the following precautions which must be observed:

A negative result in an contaminated serum could be trusted. A positive result in an contaminated serum could not be accepted, and the test must be repeated with another specimen.

No antiseptics were permissible in any of the reagents.

Haemolysis of the blood to be tested, if due to mechanical shaking in transit, did not matter; if due to alcohol or ether in the syringe with which the blood was collected it upset the reaction, though to a less extent than the Wassermann reaction.

All vessels must be scrupulously clean.

The incubation period must not exceed seven hours, owing to increased danger of false positives from contamination of the serums. Water in the water-bath should not reach more than 1/2 or 2/3 the height of the liquid in the tubes. If it stood higher convection currents in the tubes were less effective, and the results were not clean cut.

Results were to be interpreted as follows. In cases with no definite history of syphilis—

Less than 1 Σ unit, negative.

Four units and over, positive. If between 1 and 4 units, test should be repeated in case mild degree of contamination of the serum had been overlooked. If result again between 1 and 4 units, positive.

In cases with a definite history of syphilis—

Less than one unit, negative; more than 1 unit, positive.

Cerebro-spinal fluid, whatever the history, less than 1 unit, negative; more than 1 unit, positive.

Professor Dreyer then gave the following results of his test in comparison with the Wassermann reaction:

Cases.	Wassermann Reaction.	Σ Reaction.	
686	Negative	Negative	Definite history or evidence of syphilis.
322	Positive	Positive	
59	Negative	Positive	
5	Positive	Negative	No definite history or evidence of syphilis.
4	Positive	Negative	
1	Negative	Positive	

Theory of the Wassermann and Σ Reactions.

The lecturer then went into the theory of the Wassermann and Σ reactions. He came to the conclusion that there were probably two substances involved in the Wassermann reaction—a thermolabile present in all serums, and a thermostable present only in syphilitic serums. The destruction of the thermolabile substance accounted for the weakening of the Wassermann reaction often witnessed after heating the serum.

He thought that most probably the thermostable substance caused the flocculation in the Σ and Sachs-Georgi reactions, and that the thermolabile substance was responsible for the inhibition of flocculation sometimes seen in the higher concentrations, without, however, in his reaction, affecting the end titre of the serum. It was probably the occurrence of inhibition which spoilt the Sachs-Georgi reaction.

Professor Dreyer ended with the following conclusions:

1. That the reaction described had yielded results which compared favourably with those given by the Wassermann reaction.

2. That the results are quantitative as well as qualitative.

3. That the reaction can be standardized and different workers' results directly compared.

4. That the effect of treatment in a case of syphilis can be followed in a change in the unit content of the serum.

5. That consequently different methods of treatment can perhaps be compared by their effect on the Σ reaction.

ACCORDING to the New York Medical Record, telephone exchanges for physicians have been installed at Des Moines, St. Louis, and St. Josephs, while Sioux City is shortly to have a similar system. The service is described as follows: When an emergency arises and the person wishes to locate his family doctor who is a member of the exchange either at his consulting room or his residence, by referring to the telephone book he finds the note "If no answer call No. —," and the exchange immediately gets in touch with the doctor wanted either by telephone or messenger.

VENEREAL DISEASES.

THE POLICY OF THE GOVERNMENT.

The following communication, dated June 2nd, 1921, has been received from the Ministry of Health:

A circular dealing with the prevention and treatment of venereal diseases has been sent to all county and county borough authorities in England and Wales. The general conclusion of the Interdepartmental Committee which considered the question in the light of the experience gained during the war was that although certain drugs, properly and skilfully applied, may be efficacious in preventing venereal disease, the most carefully organized system for the supply of these drugs in "pockets," and the instruction of soldiers as to their use, did not produce such a general reduction in the incidence of the disease as to warrant their recommendation for general use by the civilian population. It was, moreover, found that where preventive treatment by a skilled attendant was provided, after exposure to the risk of infection, the results were better than when the same measures were taken by the individual concerned, even though he had received the most careful instruction.

Official Advice.

The Government have given careful consideration to the views of the official Interdepartmental Committee, and the unofficial subcommittee of the National Birth Rate Commission recently published, and find that there is general agreement that the best way to avoid risk of venereal disease is to abstain from promiscuous sexual intercourse, and that disinfection immediately after exposure to risk of infection is effective only to the extent to which it can be thoroughly applied in the particular case. They find that medical opinion is divided as to the practicability and likelihood of the success of self-disinfection by the civil population, whereas on the moral and social side most weighty objections have been advanced against it. In the circumstances the Government have decided that, whatever the individual or groups of individuals may practise or recommend, they cannot make a system of self-disinfection for the civil community part of their official policy.

On the other hand, the Government have decided to suggest the advisability of local authorities undertaking public instruction and enlightenment as to the dangers arising from promiscuous sexual intercourse and the disastrous consequences on the general health of the community which result from the spread of these diseases. They say: (1) These diseases are usually contracted through promiscuous sexual intercourse, and the best way to avoid risk is to avoid such intercourse. It is the duty of all individuals who have incurred, or think they have incurred, the risk of contracting disease to cleanse themselves thoroughly and immediately, and thereby diminish the risk. (2) If any signs or symptoms of disease, however slight, are experienced, the individual should promptly seek medical advice or attend a venereal diseases clinic; for any attempt at self-treatment of these diseases is likely to be disastrous.

The circular also clears up one or two doubtful points as to the continuance of experimental ablation centres, and as to the legal position of a chemist selling disinfectants against venereal diseases so long as the substances are not sold accompanied by any printed or written recommendations as to their use. It is hoped that this clear statement on behalf of the Government may form a useful basis for united co-operation of persons and societies concerned in the campaign against venereal diseases.

The Circular (No. 202) issued by the Ministry of Health is dated May 31st, 1921, and signed by Sir W. A. Robinson, Secretary. It runs as follows:

Prevention and Treatment of Venereal Diseases.

I, I am directed by the Minister of Health to state that the Government have had under consideration the policy hitherto adopted in this country for dealing with venereal diseases, and the question whether any modification of that policy is required at the present time.

2. As the Council are aware, the national scheme for the prevention and treatment of these diseases is based upon the recommendations contained in the final report of the Royal Commission on Venereal Diseases. The main recommendations of the Commission were—

(1) That gratuitous treatment for persons suffering from these diseases should be provided at hospitals and other institutions in all parts of the country.

(2) That a widespread campaign of publicity and education as to the dangers and effects of these diseases, and as to the necessity for early and skilful treatment, should be undertaken.

These recommendations have been and are being carried out under schemes formulated by the Councils and approved by the Minister of Health or his predecessors, while the propaganda campaign, in accordance with the recommendation of the Royal Commission, has been directed centrally by the National Council for Combating Venereal Diseases, under the supervision of this Department, and locally by the county and county borough councils, a large number of which have co-operated with the local branches of the National Council in carrying out measures of publicity and education. In a few areas, also, Ablution or Disinfecting Centres have recently been instituted as an experimental measure in order that facilities may be provided for the disinfection, by skilled attendants acting under medical supervision, of persons who have exposed themselves to the risk of infection with these diseases.

3. The experience gained during the war by different armies in attempting to prevent the spread of venereal diseases has given rise to question whether, in the case of the civilian community, some further measures should not be adopted with a view to diminishing the incidence of these diseases, and after the conclusion of hostilities this question was considered by an Interdepartmental Committee appointed by the Minister of Health. This Committee came to the general conclusion that although certain drugs, if properly and skilfully applied, are efficacious in preventing venereal diseases, the most carefully organized system for the supply of these drugs in "pockets," and the instruction of men as to their use, did not produce such a general reduction in the incidence of these diseases as to warrant its recommendation by the Government. It was, however, found that where preventive treatment was provided, after exposure to the risk of infection, by a skilled attendant, the results were better than when the same measures were taken by the individual affected, even after the most careful instruction. Unofficially also this question has recently been under consideration by a Special Committee of the National Birth Rate Commission, and the conclusions of that Committee are contained in a report which has now been published.

4. The Government have given careful consideration to the question on which the views of these two committees, official and unofficial, are not completely in accord—namely, the question of self-disinfection—but they find that there is general agreement on the following conclusions:

(i) That the best way to avoid risk of venereal disease is to abstain from promiscuous sexual intercourse, and that a steady and continuous policy of public enlightenment on this point, and as to the risks of venereal disease and its resulting consequences on the general health of the community, is essential.

(ii) That disinfection immediately after exposure to risk of infection is effective only to the extent to which it can be thoroughly and intelligently applied in the particular case.

They also find that medical opinion is divided on the question of the efficacy of self-disinfection for the civilian population, and in particular on such questions as (1) whether it is practicable to give such instruction to the population generally as will ensure that the disinfectants are thoroughly and skilfully applied; (2) whether the spreading of knowledge as to the efficacy of disinfectants would not lead to persons running the risk of infection who would otherwise avoid that risk, and thus increase the spread of disease; and (3) whether the disinfectants will not be used in some cases for the treatment of developed disease, with the result that proper treatment will be delayed and the cure of the disease rendered more difficult and uncertain.

5. The actual situation which confronts the Government is that there is not unanimity of opinion on the medical side as to the practicability and likelihood of success of self-disinfection for the civil population, whereas on the moral and social side most weighty objections are advanced against it. It is clear that this question is one which cannot be decided solely by reference to medical opinion—moral and social considerations of very great importance are involved in it. In the circumstances the Government have decided that they cannot give official support to self-disinfection as a policy.

6. The decision of the Government emphasizes the importance, in the interests not only of the individuals concerned, but also in those of the community in general, of continuing and extending public instruction and enlightenment as to the dangers arising from promiscuous sexual intercourse, and the disastrous consequences on the general health of the community which result from the spread of venereal diseases. The Minister is aware that in most parts of the country a wisely directed campaign has been, and is being, carried on in this direction, and he is advised that it is essential that no opportunity should be lost of educating public opinion on this matter. It is important that the Council should call to their aid every

available agency in their area which exists for the purpose of the moral and social betterment of the people, and the assistance of voluntary organizations of this kind should be most valuable in advising as to the lines on which a campaign of publicity and education can best be directed and as to the contents of such leaflets, posters, etc., as the Council may issue.

It is essential that due economy should be exercised in this matter as in all other public services at the present time, but the Minister trusts that the Council will not curtail their expenditure during the current financial year on educational and propaganda work in connexion with these diseases, and he is prepared, as indicated in paragraph (6) of Circular 192, to consider applications for his approval of limited expenditure for this purpose in excess of that incurred by the Council during the past financial year. This is a matter also in which the Council would be justified in looking to voluntary bodies for some financial assistance.

7. The question of the contents of any publications which may be issued by the Council on this subject is one for the decision, in the first instance, of the Council, but the Minister desires to suggest the advisability of the widespread issue of leaflets, etc., warning the public of the dangers of venereal diseases and containing advice on the following lines:

(1) The prevalence of venereal diseases is a grave source of danger and ill health to the public.

(2) These diseases are usually contracted through promiscuous sexual intercourse, and the best way to avoid risk is to avoid such intercourse. It is the duty of all individuals who have incurred, or think they have incurred, the risk of contracting disease, to cleanse themselves thoroughly and immediately, and thereby diminish the risk.

(3) If any signs or symptoms of disease, however slight, are experienced the individual should promptly seek medical advice or attend a Venereal Diseases Clinic.

(4) Any attempt at self-treatment of these diseases is likely to be disastrous.

8. The Minister is of opinion that the arguments which have influenced H.M. Government in deciding against any official advocacy of self-disinfection do not apply to the provision of Ablution Centres where facilities are provided, with proper safeguards, for disinfection by skilled attendants acting under medical supervision.

The experience so far obtained is not sufficient to enable any final conclusions to be drawn as to whether such Ablution Centres should be established permanently in large towns; but the evidence available as to the results obtained in different armies from the provision of these centres justifies further experiments of the same kind for the civil population. The Minister is accordingly prepared to recommend for his approval of the experimental Ablution Centres.

9. It is understood that questions have arisen as to the precise effect of section 2 (2) of the Venereal Disease Act, 1917, and the Minister considers it desirable to state that, although he is not empowered to give an authoritative interpretation of the provisions of any Act of Parliament, he is advised that a chemist does not commit an offence by selling any substances for which he is asked, merely because those substances are capable of being used as disinfectant for venereal diseases, so long as the substances are not sold by any written or printed recommendation to use. It should be carefully borne in mind that sections 1 and 2 (1) of the same Act, an offence is committed by any person (other than a duly qualified medical practitioner) who for reward direct or indirect, treats, prescribes for, or offers advice in connexion with the treatment of venereal disease, and by any person who does any of these things or even offers to do them, by advertisement, public notice, or announcement.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

THE annual general meeting of the Society for the Prevention of Venereal Disease was held at the house of the Royal Society of Medicine on June 6th, under the presidency of Lord WILLOUGHBY DE BROKE. The report of the year's work, read by Dr. WANSEY BAYLY, the Secretary, recorded that the society's efforts had been concentrated on maintaining that mass of public opinion which it had created in its policy. These efforts had taken the form of press propaganda, addresses to trade union and other organizations, debates and conferences, and the circularization of members of public bodies. The number of county and borough councils which had adopted the society's policy had increased from twelve to twenty. A branch had been formed in New Zealand, one was projected in South Africa, and propaganda was proceeding in Canada and in Jamaica. The report of the Birth-Rate Commission in its medical aspects was claimed as an endorsement of the society's policy. The treasurer's report revealed a total income for the year of £922, and an expenditure of £878.

Lord WILLOUGHBY DE BROKE said that venereal infection still constituted a grave danger to the public welfare, in spite of the official policy, which consisted

of exhortations to be chaste, warnings against the danger of unchastity, and advice to the incontinent to go to the doctor on becoming infected. All these were essential in dealing with the problem, but they were demonstrably insufficient. Two further lines of action were possible: one consisted of disciplinary methods, such as compulsory notification and detention, but these measures were highly contentious, and in any case would involve legislation and consequent delay. The other line of action was the provision of means of immediate self-disinfection, and this was the society's policy. Recently the Ministry of Health had issued a circular to the county and borough councils in which it was stated—

"It is the duty of all individuals who have incurred or think they have incurred the risk of contracting disease to cleanse themselves thoroughly and immediately, and thereby diminish the risk."

That, with the substitution of the word "disinfect" for "cleanse," might have been written from the offices of the society. The society had endeavoured to persuade the Ministry of Health to alter the Act of 1917 by allowing chemists to sell recommended disinfectants under the Government's imprimatur, but the Minister had stated that there were moral and social considerations to be taken into account before self-disinfection could be embraced as a policy. In face of the admission he had just quoted the society should now approach the Ministry with a view to removing the disability of chemists, and should assert itself as the proper body to take the risk and responsibility of issuing instructions and recommending disinfectants. He moved:

That the Society for the Prevention of Venereal Disease take immediate steps to apply formally to the Ministry of Health for their sanction, under the Venereal Disease Act, 1917, of the preparation and sale by chemists, under the supervision and control of the Society for the Prevention of Venereal Disease, of the materials for immediate self-disinfection recommended by them.

Lady ASKWITH seconded the resolution, and it was carried unanimously.

Sir FREDERICK MOTT supported the society's policy, because he believed it to be the only one which could effectively combat the disease. Human nature was not going to be changed at once by moral persuasion, especially having regard to the psychological disharmony prevailing at present in social life. It was said on the Birth-Rate Commission, by those who supported the policy of the National Council, that self-disinfection in the army had not produced the happy results expected. But any method of self-disinfection must be efficiently carried out, with strict observance of the regulations and instructions. When disinfection was carried out under proper conditions—as Sir Archdall Reid had shown at Portsmouth—the success was phenomenal. The early ablution centres of the Government were not materializing. One was in existence (at Manchester) and five were in prospect, but there were 183 curative treatment centres, and therefore there should be 183 areas in which prophylaxis was necessary. Nor would these centres be likely to multiply, because the ratepayers objected to this burden. The society's policy of immediate self-disinfection was therefore called for, and in order that it might be efficient there must be the means of obtaining the disinfectants, and the proper instructions for their use, without trouble.

Dr. J. H. SEQUEIRA said that the upholders of the official policy appeared to rejoice in the increased numbers attending the clinics, whereas a matter for congratulation would rather be diminished numbers at the clinics and a larger proportion of those who had been foolish enough to risk contagion seeking the means of self-disinfection.

Other speakers were Lieut.-General Sir FRANCIS LLOYD, who commented on the unwillingness of public bodies to face the situation; Miss NORAH MARCH, who described propaganda among women's organizations; Rev. HUGH CHAPMAN, the only clergyman as yet officially connected with the society; and Miss ETTIE ROUNT, who gave reasons for the failure of self-disinfection in the Rhine army. These reasons were chiefly that the prophylactic system in its direction from London was weak and timid and the outfit out-of-date; there was great laxity and half-heartedness among many of the field officers; officers who permitted a high rate of infection to arise or continue in their ranks were not demobilized, and soldiers who contracted the disease were not punished sufficiently to deter them or to make them particularly anxious for self-disinfection.

The officers and members of the Executive Committee of the society were re-elected.

British Medical Journal.

SATURDAY, JUNE 11TH, 1921.

A NEW STUDY OF APHASIA.

I.

DR. HENRY HEAD in his Hughlings Jackson Lecture for 1920¹ reviewed the subject of aphasia from the historical standpoint. His Linares Lecture² had dealt with the clinical aspects of disorders of speech. The two lectures are inseparable, and in order to appreciate the importance of Dr. Head's suggestions, the Hughlings Jackson Lecture claims our first consideration.

In the past many hypotheses as to the cerebral localization of speech have been accepted which were neither provable nor useful. In the Middle Ages the brain was supposed to contain three ventricles, of which the anterior was the seat of sensation, the middle that of cogitation and reasoning, whilst the posterior was assigned to memory. Descartes and the philosophers of the seventeenth and eighteenth centuries swept away the materialism of the schoolmen, with the result that no one presumed to correlate directly the activities of the mind with the life of the brain. Gall was the first to insist that the intellectual processes of the mind were materially bound up with the integrity of the brain. His attempts to localize mental functions and moral faculties in the brain were based on the observed effects of injuries; and, although his conclusions may have been fantastic, there was sense in his plea for examination of the brain from the spinal cord upwards. In 1861 Broca described a definite clinical condition which he called "aphemia," produced by destruction of brain substance, and he believed that he had found the faculty of articulated language in the third frontal convolution. Interest in the question of the localization of speech rapidly spread to England, and in 1864 Hughlings Jackson published his first paper on "Loss of speech, with hemiplegia of the left side." Broca and Jackson took part in a discussion on aphasia at the British Association in 1868, so that their views can be readily compared.

The clinical observations of Broca were clear and precise. He recognized two main groups of speechless patients. First, the "aphemic," who has a reduced vocabulary and may be speechless except for a few monosyllables which do not seem to belong to any language. Yet his ideas appear to be intact, he can understand what is said to him, and he recognizes words and phrases which he cannot repeat. The "amnesic" patient, on the other hand, can pronounce words, but they have no bearing on the ideas he wishes to express. He has not lost all kinds of memory, but he no longer recognizes the conventional association between ideas and words either spoken or written. Up to this point Dr. Head admits that Broca's statements are consistent with fact. But the larger number of cases do not correspond with these two clean-cut divisions, and this hampered the determination of the localization of the lesion. Broca himself insisted that it is aphemia only which is caused by a lesion of the third frontal convolution.

Hughlings Jackson, on the other hand, contemplated a holder and wider conception of speech and its disorders. He failed to command the attention of the medical world, either at that time or later, because he declined artificially to simplify problems which he realized to be intricate and immensely difficult. Jackson did not shrink from approaching the subject from the psychological as well as from the anatomical side, and psychology was in those days considered utterly remote from clinical medicine. He pointed out that healthy language consisted of two distinct but usually inseparable forms: (1) Intellectual—that is, the power to convey propositions; (2) emotional—the ability to exhibit states of feeling. These two are separated by disease. In most cases it is intellectual language which suffers; emotional language usually escapes. The power to form propositions is affected, and not the memory of words or faculty of language. The higher the propositional value of the task the patient is asked to carry out the less he will be able to respond, whereas the lower or more automatic the task the easier will it be to perform. This is the basis of Hughlings Jackson's treatment of disorders of speech.

The temptation to appear simple even at the expense of accuracy was, however, too great for Jackson's contemporaries. They were fascinated by diagrams which could be memorized without necessarily understanding the problem involved. Bastian, Baginsky, Wernicke, and Liechtheim headed a veritable school of "diagrammatists," who, as Head says, "were compelled to lop and twist the clinical facts to fit the Procrustean bed of their hypothetical conceptions." Nevertheless they held the field almost unchallenged until, in 1905, Pierre Marie startled the medical world by a pronouncement which Mott described as "an earthquake to our cherished beliefs in cerebral localization." Marie asserted that the third frontal convolution does not play any special part in the function of language, and that "sensory" aphasia could no longer be accepted. Marie's views led to heated discussions on such terms as "Broca's aphasia," "total aphasia," "word-blindness," and "word-deafness," which, Head remarks, are pure phrases not corresponding to any clinical phenomena. Marie claimed that Broca's aphasia was always accompanied by a marked diminution in the general intelligence, that it was not a special loss of word memories, but a defect partly of general intelligence and partly of special intelligence of language. Jackson had appreciated this long before and had gone much further towards analysing the intellectual defects involved. But his writings were forgotten or remained unread. They bristled with difficulties, and lacked the fluent dogmatism of his contemporaries.

The summary of Hughlings Jackson's views given by Dr. Head may be condensed as follows:—(1) Aphasic patients may be divided into two groups: in Class A the patient is almost speechless, though he may utter one or two unvarying words or jargon; Class B comprises those who have plentiful words but habitually use them wrongly. (2) Loss of power to carry out an order depends on the complexity of the task; the more abstract the conception, the more difficult its execution. (3) Higher and more voluntary aspects of speech suffer more than lower, and automatic; hence emotional and impulsive utterances may be retained. (4) Writing is affected not as a separate "faculty," but as part of the failure to propositionize in words. (5) Defects in reading are not due to some loss of function called "alexia," but to an inability to reproduce a proposition which may none the less be received accurately. (6) Imperception,

¹Brain, vol. xliii, p. 350.

²Ibid., Part 2, vol. xliii, p. 87. See also Head, "Disorders of Symbolic Thinking and Expression," *British Journal of Psychology* (General Section), vol. xi, Part 2, p. 173.

is on the receptive side what "aphasia" is on the emissive. Defects of speech are caused on the emissive side by inability to form or express a proposition in words; on the receptive by failure of those mental processes which underlie perceptive recognition. (7) External and internal speech are identical, except that the former is exhibited in the utterance of articulated words, whilst the latter can be discovered by writing only. (8) External and internal speech depend upon the formulation of a proposition which can be verbalized in speech or writing. If the patient cannot formulate to himself and retain a sequence of abstract propositions, the emissive aspect of speech will be affected. (9) If to this defect is added "im-perception," the patient will show impaired comprehension as well as impaired speech. (10) In the majority of cases with defects of speech mental images are unaffected, notwithstanding that almost every hypothesis propounded in the last forty years presupposes some defect in auditory or visual word images.

Thus it is evident that the teaching of Head no less than that of Hughlings Jackson brings us back for our starting point to Locke's view of language—namely, the use of articulate sounds as marks or signs of ideas within a man's own mind whereby they may be made known to others and the thoughts of men's minds be conveyed from one to another. We propose to indicate some of the consequences of this doctrine in another article.

THE AMERICAN UNIVERSITY.

AFTER the London Conference of all the Universities of the Empire in 1919 the Administrative Committee of the Australian universities felt that an era of greatly extended and improved relationship between the universities of the world had begun, and that, if Australia were to keep its place among them, more must be known of the highly important American group. Accordingly, the chairman of the Administrative Committee spent three months in America, and, without any idea of publication, wrote a report designed to furnish the Australian universities with answers to certain questions concerning the American universities. At the wish of the University of Sydney, Professor E. R. Holme has now published part of this attractively written report,¹ which he modestly describes as a preliminary survey of a very wide field, and as but the first impression of a very large subject. Some account of what he has to say will, we believe, be of interest to many readers in this country.

The typical American university is in a period of transition to an improved method of government and administration. The numbers of students have increased since the war, though (probably from the protection exercised by restriction of entry) there is no parallel to the fourfold increase of students reported at Liverpool. A fundamental difference between the American universities and those at Oxford, Cambridge, in Scotland and in Australia is, that the former continue to be responsible for a very great amount of secondary education, such as is carried out by our public schools; the reason for this is that the period of four years of American high school education, intended to cover the pupil's school time from his 14th to his 18th year, is not long enough; and one result is that a well-trained American student graduates in medicine two years

later than a well-trained European. The American school system, copied from Prussia, is not one for imitation in Australia, which directly inherited the British scheme—one regarded as providing a good sound basis for development. The matriculation requirements naturally vary among the different universities, but entrance by leaving certificate or high school graduation diploma is one of the essentials. If the university could enforce a proper entrance standard in appropriate subjects, much benefit would accrue to secondary education; there appears, however, to be considerable risk that the influence may work in the opposite direction and that the university entrance standard may be pulled down to the low average level of high school training in schools that have little need to prepare students for universities. There is indeed too much competition for students among American universities, and this naturally exerts an influence adverse to the maintenance of matriculation standards. Nevertheless it is remarkable how good both in quality and quantity is the work accomplished by the American university upon the insufficient and unsafe basis of American public secondary education; it trains its undergraduates to be university men and women all their lives, and by means of associations of alumni (fraternities) and alumnae (sororities) and of publications keeps them mindful of the obligations of academic citizenship. This "class" system—a characteristic American tradition—keeps fellow students permanently in touch, and there is no doubt about the vast and beneficent influence exerted by the universities on American society.

American universities have suffered from the example set by modern competitive methods in business; for a university is not a mercantile venture, and the autocratic powers vested in the president of a university, to whom there is no corresponding official in British universities, undoubtedly has potentialities for harm. There is also, perhaps, too much administrative machinery in American universities, and the attraction of able men out of professorships into administrative posts by apparently higher positions and actually better emoluments is a bad policy. Out of 150 institutions styling themselves universities forty are State universities, and being therefore more generously supported are thus able to supply the deficit not met by the students' fees. The future of the American university should be predominantly on these lines, for, though they are more exposed than endowed universities, such as Harvard, Yale, Princeton, and the Johns Hopkins, to popular influence which might force them to derogate from the higher ideals of a university, it does not appear to be a sound criticism that they are more utilitarian in their motives, for all universities are much concerned with utilitarian purposes, and through the ages have given professional training—for example, in medicine. But the State universities obviously cannot specialize in divinity, and are less impeded than the old endowed universities in making a speciality of the modern sciences and the mechanical arts. In accordance with the Land-Grant Acts, the first in 1862 being known as the Morrill Acts, Congress has allotted to State universities, and for their foundation in States without universities, grants of land. This federal aid to universities is under the general supervision of the Federal Bureau of Education, which is a section of the Department of the Interior. It is rather remarkable that there is not in the United States a university that is a federal institution, and therefore national in the specific sense, especially as George Washington urged the foundation of such a university and left a bequest for its endowment.

¹The American University: An Australian View. By E. R. Holme, Professor of English Literature in the University of Sydney. Sydney: Angus and Robertson, Ltd. 1920. (Cr. 8vo, pp. 242. 7s. 6d.)

The really typical American graduate university justly has a high reputation; thus Harvard is famous among all English-speaking peoples in law, and is rising as high in medicine, though in this respect the Johns Hopkins, with distinctions in many other subjects—of which some, such as political economy, are comparatively recent—is perhaps better known. The new development of the University of Minnesota in connexion with the Mayo foundation is rightly mentioned here. It appears that the separation of undergraduate from graduate work has now gone far enough in America. Professor Holme considers that the separate undergraduate university for women is one of the most valuable of the American contributions to higher education, and he refers to the voice recently raised in prayer in this country for at least one women's university and at least one for men only. In the interesting chapter on university extension, which has developed to such a remarkable degree in America, an account is given of the Chautauqua movement begun in 1874; tens of thousands make a kind of Canterbury pilgrimage to this lake-side summer resort, where a holiday may be combined with almost any form of study, and a degree obtained after three years, in each of which six weeks' work is done in Chautauqua classes, the intervening time affording opportunity for reading Chautauqua textbooks.

Though Professor Holme considers it impossible for Australia to copy the American university, which is totally un-British, and Australian universities must develop on the lines of British tradition as long as the Australian people remain a growth from the old stock—97 per cent. of which has the British Isles for its ancestral home—Australia may receive from America some precedents of obvious value, such as those of the "Dormitory," administration, federal aid, and graduate studies which are all critically examined.

THE BIRTHDAY HONOURS.

THE Birthday List contains some honours which will be received with more than ordinary satisfaction by the medical profession. In the first place it is to be noted that the honour of knighthood is conferred on two of the brightest illustrations of scientific medicine—Professor Arthur Keith and Dr. Thomas Lewis. Sir Arthur Keith has added lustre even to the post of Conservator of the Museum of the Royal College of Surgeons of England; he is equally at home in discussing the antiquity of man and in expounding the historical and comparative application of the abstruser truths of anatomy to every-day surgery, medicine, and anthropology. Sir Thomas Lewis is described in the list as honorary consulting physician since April, 1918, to the Ministry of Pensions; in that capacity and as Director of the Medical Research Council's Department of Clinical Research in the cardiographic department of University College Hospital Medical School he has formed one of the most interesting clinics in London, but before and since he has laid the profession in all countries under a deep debt of gratitude by reason of the originality and accuracy of his experimental observations on the mechanism of heart function, and the sanity and clarity of his application of these experimental researches to practical medicine. He is physician to University College Hospital and lecturer on cardiac pathology in its Medical School. His most important contribution to literature is the volume, the second edition of which appeared recently, on the *Mechanism and Graphic Registration of the Heart Beat*. Dr. Sydney Russell Wells, who also receives the honour of knighthood, has been Vice-Chancellor of the University of London since 1919; he, too, is known for his study of disorders of the heart. Dr. William

Henry Willcox, who receives the distinction of K.C.I.E., is physician at St. Mary's Hospital, and was known before the war as medical adviser to the Home Office. As consulting physician to the forces in Mesopotamia he was a colleague of the late Sir Victor Horsley, and afterwards as medical adviser rendered important services to the civil administration in Mesopotamia. We have had the opportunity of publishing an account of many of his observations in these capacities, and in particular those on the cause and prevention of scurvy and beri-beri, and on the nature, prevention, and treatment of heat hyperpyrexia, while his interest in general clinical subjects is shown by the paper published only last week on infective arthritis in its relation especially to infection of the teeth. Major-General Sir William Rice Edwards, who also receives the K.C.I.E., entered the Indian Medical Service in 1885 and became Director-General in 1918. Much of his early service was spent on the North-West Frontier. He was on Lord Roberts's staff in India in 1890 and again in South Africa in 1900, where he much distinguished himself and received the C.M.G. In 1913 he was appointed Inspector-General of Civil Hospitals, Bengal, and in the following year became C.B. His work as an administrator has been marked by a statesman-like grasp of the medical situation in India and an appreciation of the need of improved medical and post-graduate education and of extended opportunities for research. While in Bengal he gave his aid in the foundation of the Calcutta School of Tropical Medicine; since he became Director-General he has shown a like interest in the establishment of the Bombay School of Tropical Medicine and has directed the energies of the Indian Medical Research Fund into some new and fruitful fields. He has been a loyal friend of his own service, whose cause he has championed without fear or favour in troublesome times; the success which has attended the efforts of the British Medical Association to remove some of the disadvantages under which the Indian Medical Service has laboured has been due in no small measure to his sympathy. Surgeon Rear Admiral P. W. Bassett Smith, C.B., who is promoted to be K.C.B., rendered important services both before and during the war while attached to the Royal Naval Hospital at Haslar and to the Royal Naval Medical College at Greenwich. The honour of knighthood is conferred upon Dr. F. Conway Dwyer, surgeon to the Richmond Hospital, Dublin, inspector of anatomy in Ireland, and formerly president of the Royal College of Surgeons in Ireland. A like honour is received by Brigadier-General Donald Johnstone McGavin, C.M.G., Director-General of the New Zealand Army Medical Service. The distinction of C.B. is conferred on Colonel Charles Edward Pollock, C.B.E., assistant director of the Medical Service, Eastern Command. The honour of C.I.E. is received by Lieut.-Colonel Benjamin Hobbs Deare, I.M.S., Principal of the Medical College, Calcutta, and Dr. Mohendra Nath Banerjee, principal of the Carmichael Medical College, Belgatchia, Bengal. The Kaisar-i-Hind medal is awarded to the Rev. Ernest Muir, M.D., missionary and research worker in leprosy, Bengal.

WOMEN AT CAMBRIDGE.

On June 4th, by a narrow majority of 116 to 111, the Cambridge Senate approved a grace authorizing a vote to be taken on June 16th upon both of the alternative propositions for regulating the relation of women students with the University. Votes for both graces will be accepted at the same time. In the event of the first being carried, the second will be withdrawn, and the votes destroyed. The present position arises directly out of the rejection last December of Report A of the Syndicate appointed to consider the question.¹ That rejection, together with the obvious impracticability of giving effect to Report B in

¹ BRITISH MEDICAL JOURNAL, August 21st, 1920, p. 234, and December 18th, 1920, p. 255.

face of the opposition of the governing bodies of the Women's Colleges, left the matter in a position admittedly unsatisfactory. The first proposal is the result of an informal conference of both parties, convened by the Vice-Chancellor, and the 187 signatures to the memorial, in which the scheme was submitted in April, include the names of fifty members of the Senate who voted *non placet*, and twenty-two who did not vote on December 8th. There is this evidence for a substantial measure of agreement upon the compromise which it embodies. The chief points in the scheme are (1) that women students would be matriculated members of the University, and security of admission to university teaching would be obtained; (2) that all degrees would be open to women; (3) that women would be eligible to be members of Boards of Studies, and for Professorships, Lectureships, Examinerships, etc., as well as for Prizes and Studentships; (4) that two women Assessors would sit on the Council of the Senate, with a consultative voice but no vote; (5) that the number of resident undergraduate women would be limited to 500, or such larger number as the University may from time to time prescribe by grace; and (6) that the discipline of the women students would be in the hands of a Board of Women, with two men Assessors. The scheme, as outlined above, definitely excludes women from membership of the Senate, and so falls short of granting the full membership for which the women had hoped. The compromise is, however, acceptable to the governing bodies of Girton and Newnham Colleges, who have signified their intention of refraining from the contemplated appeal to the Royal Commission if it is passed before that body concludes its inquiry. The second proposal is for the admission of women to purely titular degrees. This is a concession to which the women's colleges offer uncompromising opposition. They maintain that it would not materially ease the difficulties under which the staffs of the women's colleges at present labour, and that it would leave the difference in the status of women at Oxford and at Cambridge so clear that it is unlikely to do much towards stemming the alleged increasing tendency for the abler girls to turn to Oxford. It is announced this week that the Council of the Senate has now decided to postpone the vote on the relation of women with the University from June 16th to October 20th, on account of travelling difficulties.

RATS, SHIPS, AND CREWS' QUARTERS.

At the annual meeting of the Association of Port Sanitary Authorities Dr. A. K. Chalmers, who is the medical officer to the Port Authority as well as to the City of Glasgow, introduced a discussion on what he called "de-ratisation of ships at British ports." His subject had nothing to do with the rates, and the word was, we believe, pronounced as though it were spelt with two t's; at any rate the subject debated was the destruction of rats, and, in particular, the need for some uniform method. It might be thought that the problem would be fairly simple in a self-contained place like a ship—we believe a ship to be a "place" for certain purposes—but there are difficulties, among them the obligation to use a fumigant which will not injure the cargo, and it is to be noted that it may be desirable to fumigate ships which are never completely unloaded at any one time at a British port. Another matter on which uniform practice was deemed desirable is the need for the regular destruction of rats after each voyage. Dr. Chalmers pointed out that though plague was primarily a disease of rats, there was no evidence that the rat plague in Eastern countries had diminished the number of rats; millions of rats had died of it in India, but there were as many there to-day as twenty years ago; not only were they numerically as strong, but from a bacteriological point of view their position was even stronger, since they might suffer from a chronic non-fatal but transmissible

form of the disease. Again, at Copenhagen, when the authorities set out to trap and kill rats, the average catch was about 300,000; it was rapidly reduced by half, but remained at 150,000 for some time. It appeared that as fast as rats were killed the birth rate rose; it was only by the adoption of a special policy which consisted in killing the females and liberating the males, who fought and exterminated each other, that the catch was reduced to 90,000. The general opinion of the meeting seemed to be that though it was possible to diminish the number of rats on ships it was impossible to exterminate them in the ports. Eventually a subcommittee was appointed to confer with the appropriate Government department in the hope of devising some unified method for the mitigation of the evil. A discussion also took place on hygiene in crew spaces; it was introduced by Dr. J. Howard Jones, M.O.H. Newport Port Sanitary Authority, after communications from that authority, from the Hull and Goole authority, and from the River Tyne authority had been considered. Various speakers pointed out that the crews' quarters often needed improvement, and that some ship-owners were willing to make improvements, but that the seamen themselves would need education in order to appreciate them. A committee was appointed to investigate the matter and make a report to the council.

PURE AND CLEAN MILK.

In the JOURNAL of March 6th, 1920, p. 336, some account was given of the steps taken by certain public-spirited milk producers in this country to supply clean fresh milk free from the virus of tubercle or any other disease. For some time before March 14th, 1920, the Food Controller, acting in concert with the Ministry of Health and the Scottish Board of Health, had granted licences permitting the use of the designations "Grade A" and "Grade B" for milk of high hygienic quality. Since that date the system has been replaced by a modified plan not less exacting in its requirements. The Ministry of Health issues licences for two sorts of milk—"Grade A milk" and "Grade A (certified) milk"—and no person is allowed to use either designation save under licence by the Ministry. Our article described the conditions that must be fulfilled in the case of each kind. The licence for Grade A milk lays down strict requirements in regard to such matters as tuberculin tests for the cows, sampling of the milk, inspection of the farm, cooling of the milk on the farm, and its consignment in a sealed container labelled to show the address of the farm, the day of production, and whether from the morning or evening milking. In the case of Grade A (certified) milk further precautions are enforced. The milk, after cooling, must be bottled on the producer's premises in sterilized bottles, and labelled to show the day and time of production. Before delivery to the consumer it may not contain *B. coli* in one-tenth of a cubic centimetre (in each of two tubes) nor more than 30,000 bacteria per cubic centimetre, nor may it be delivered to the consumer as Grade A (certified) milk more than two days after the day of production. Further, it must be delivered to the purchaser in the bottles in which it has been received from the producer with caps intact. For both kinds of Grade A milk there are stringent conditions as to the employment of tuberculin for testing the health of the herd, and periodical veterinary examinations of the animals are required. Last week Dame Margaret Lloyd George opened the Grade A (Certified) Milk Dairy, recently established by the Express Dairy Company at College Farm, Finchley. The ceremony—under the chairmanship of Viscount Elvedon, President of the Grade A Milk Producers' Association—was attended by a number of medical officers of health and other members of the medical profession. The visitors had an opportunity of seeing the special herd at milking time, and of observing the details of production, bottling, and laboratory control. It is of some interest to recall that a strong advocate of milk pasteurization, speaking of ideal reforms in an address delivered

thirteen years ago, laid down the following conditions which would have to be fulfilled in the technique of pure milk production: "In order to get milk with a bacterial content of less than 1,000 per cubic centimetre, such as von Behring regards as a not unattainable ideal, or even of less than 10,000, which is the standard for 'certified milk' at Rochester (N.Y.), you must be prepared to devote money and careful attention to the problem. The animals must be kept scrupulously clean. Complete asepsis must be aimed at in milking. The cows' tails, for instance, must be cleaved with an antiseptic wash. Before milking begins it ought to be possible to pass a white kid glove over the cow's udder without staining it. The milker's hands should be washed with special precautions before milking each cow, and special milking suits should be worn. A special cooling room must be available, and the milk should be filled into bottles and sealed for delivery as soon as possible. Always it must be kept cool. The bottles employed must be thoroughly cleaned and sterilized before the milk comes into them. To say nothing of the machinery required, it is obvious that all this needs conscientious workpeople." It would need but a few slight changes to turn this into a description of what actually happens to-day in the production of Grade A (certified) milk in England.

A BYWAY OF EVOLUTION.

DR. WALTER KIDD'S observations on the direction of the slope of hair on the bodies of mammals are well known to anatomists; they have extended over many years, and, did they do no more, would furnish ample evidence of his perseverance and capacity for taking pains. He has now gathered them together in a book,¹ and added many new examples. Shortly stated, his main purpose is to show how this line of evidence lends support to the Lamarckian, or rather, perhaps, the neo Lamarckian, conception of evolution. Dr. Kidd considers that, apart from the centrifugal forces of the growing hair, the main causes of the formation of whorls, featherings, crests and other patterns of hair may be a certain centripetal force either in the form of friction, pressure, gravitation or muscular traction. These centripetal forces are the all-important factors. That muscular traction does have an influence on the direction of the individual hair is generally admitted—the erector pili muscle, for example. A more general expansion of a skin muscle, such as the platysma, can quite conceivably exert a more general effect on the hairs collectively over an area of skin. Another factor in this connexion does not appear to be mentioned—it is the shape of the individual hair on transverse section; this point is illustrated in the lie of the hair of a negro and a Malayan for example. The shape of the hair in all mammals is certainly not the same. The up-standing condition of the hair in *Choloepus*—certainly, as appears from the picture given, very striking—is attributed by the author to the effect of gravitation; but this effect is not nearly so well marked in *Bradypus*, an animal of similar habits. Moreover, the hair on the ventral surface of quadrupedal mammals, upon which gravity is constantly acting, is not erect as a general rule. Presumably Dr. Kidd would suggest that the intermittent pressure when the animal is lying down is sufficient to overcome the ever-present effect of gravity. It is, however, when one comes to examine the hair direction in horses and the author's explanation of the effects of harness that it becomes difficult to accept fully his conclusions. The evidence of the diversity of effect on the direction of the hair due to the pressure of a tightly or a loosely fitting collar, for example, is unconvincing and the critic is tempted to ask certain apparently trivial but nevertheless pertinent questions. How long, for instance,

is it necessary for a horse to wear a particular collar before a specific effect is produced on the direction of the hairs? And further, if there is a change of collar from a tightly fitting to a loosely fitting, or vice versa—as, for example, on a change of ownership—does the direction of the hair, once established, become altered? Granting, however, for the sake of argument, that these hair patterns are due to the causes stated by Dr. Kidd, the really crucial point is, What evidence is there that these acquired characters are inherited? The only evidence that, so far as we have observed, Dr. Kidd records on this point has reference to ten foals stated (p. 136) to have had the same hair pattern as their mothers; in them the particular patterns are supposed to have been produced by the harness. Though the number is small, yet, if the proof of the inheritance of the acquired character were conclusive, it would be a really important point. But in another place (Chapter V) the author describes "fourteen out of a much larger number of the most instructive varieties of pattern" which he has collected. If the varieties of pattern are so numerous, it is not surprising that a foal should sometimes be born with the same pattern as its mother. What happens if the sire has acquired a different pattern from the mare? There are too many questions to which no reply is as yet forthcoming. Dr. Kidd speaks of the "unpopular doctrine of Lamarckism." Unpopular it is only in the sense that it is not accepted for lack of scientific proof. Many biologists would welcome it were the proof satisfactory. It would solve many difficulties; it would be of vast assistance in the solution of many a problem in sociology. Such evidence is not forthcoming as yet, and it is not to be found in the volume under consideration. As has been said, the book furnishes ample evidence of the author's perseverance and enthusiasm in the collection of material; it is a pity that he introduces so much that is irrelevant and indulges in a style that is often one of unnecessary levity.

SPORT BY ARTIFICIAL LIGHT.

THE present hyperactivity of the sporting instinct is resulting in a demand for artificial illumination of games, even of games played entirely out of doors, partly that the zestful hours may be prolonged, and partly that the players may be rendered independent of the glare and vagaries of the sun. In the discussion at the Illuminating Engineering Society on May 31st, instances were given of how the artificial illumination of sports and games is being put into practice in America. In Chicago a baseball ground is illuminated at night by horizontally directed searchlights proceeding from lamps so placed around the arena that they do not, it is said, dazzle either the players or the spectators. In New Jersey, not only tennis courts in the open but even golf links have been lighted by incandescent gas. The holes on the links are painted white inside so as to be more easily visible. The artificial lighting of tennis courts is fairly well understood in this country, but night golf is something new, though there is a record of a golf match at Highgate which was finished by means of flares. It would seem feasible for golfers to practise putting by artificial light, and for cricketers to practise at the nets, although the illumination of an entire course or field might be out of the question. To judge from the discussion, however, it is the view of some promoters of sport that sunlight is considerably below artificial light in efficiency when the latter is properly distributed and controlled. In some future cricket test the wickets may fall by night instead of by day, which will bring another minor revolution into the habits of a large part of the community. In the case of indoor games the illuminating engineer is more sure of his ground. The illumination of the billiard table is already standardized. With the chess table it is different, and the loser might plausibly attribute his false moves to the dense shadows cast by the pieces when the light of the board

¹ *Initiative in Evolution*. By Walter Kidd, M.D., F.R.S.D. 1921. London: H. F. and G. Witherby. (Med. 8vo, pp. 272; 80 figures. 15s. net.)

comes from an unduly oblique angle. There is some reason to believe that the watching of the swift passage of a ball, either at tennis or cricket, in indifferent or too brilliant daylight has caused injury to eyesight; eager interest in the game has made both spectators and players oblivious of conditions of eyestrain which they would resent and correct under other circumstances. Any study of illumination in this connexion, therefore, is likely to be useful, even if it does not serve the immediate object of turning the sportsman's night into day.

CLINICAL RESEARCH IN PHARMACOLOGY.

In 1913 Professor Brauer, who occupies the Chair of Medicine in the University of Hamburg, put forward a proposal for the establishment of a research institute for clinical pharmacology. The main underlying idea was to bring about a greater measure of co-operation between the clinician and the pharmacologist. The observations of the pharmacologist on the action of drugs on animals and human beings, if unchecked by clinical observation, are of limited value, and in some instances may be misleading. Professor Brauer failed to obtain financial aid either from the State or from chemical manufacturers, the latter professing a fear that the scientific freedom of the staff might be diminished should manufacturers contribute to the support of the proposed scheme. Nevertheless Professor Brauer obtained enough from an anonymous donor to fit up rooms at the Eppendorfer Hospital. The details published in an article in the *Deutsche medizinische Wochenschrift*, on which we have to rely, are very incomplete. It would appear that the institute, so to call it, is recognized by the university and enjoys full scientific independence.

PRESENTATION TO DR. MACDONALD.

THE presentation to Dr. J. A. Macdonald will be made during the annual meeting of the British Medical Association at Newcastle. It is therefore necessary to close the fund, and any member who intends to subscribe and has not yet done so should send his cheque to the Medical Secretary, 429, Strand, W.C.2, at once. It was during the annual meeting at Cambridge last year that Dr. Macdonald ceased to be Chairman of the Council of the Association, after holding that office for ten difficult years. He was a member of the Representative Body from the beginning, and became its chairman in 1906, so that when he was elected Chairman of Council in 1910 he already had considerable experience of the business of the Association. He never grudged time or energy in its service, and it is very fitting that the occasion should be taken to give him some tangible expression of the gratitude of its members.

WE regret to announce the death, on June 2nd, at the age of 51, of Dr. J. M. Fortescue-Brickdale, Physician to the Bristol Royal Infirmary.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Public Health Officers Bill.

THE private bill introduced by Sir Philip Magnus was considered on Report, on June 3rd, as amended in Standing Committee. The first clause set forth that the medical officer of health of a local authority, who by the terms of his appointment was restricted from private practice as a medical practitioner, should not be appointed for a limited period only, but should be removable by the authority with the consent of the Minister of Health, or by the Minister, but not otherwise. Sir Philip Magnus, under a promise made in Committee, moved to insert the words "in cases to which this section applies." This amendment having been agreed to, he moved as an addition to the clause the words:

This section applies to:

(a) the medical officer of health of a county borough where any portion of the salary of the medical officer was paid out of moneys voted by Parliament before it was constituted a county borough;

(b) the medical officer of health of a county district any portion of whose salary is paid out of the county fund of the county in which the district is situate and charged to the Exchequer contribution account.

On a division the amendment was carried by 100 votes to 17.

The second clause made similar provision as to tenure of office and appointment of sanitary inspectors, but with the provision that where more than one sanitary inspector was appointed by a local authority the clause should only apply to the senior sanitary inspector. Under the bill inspectors of nuisances are to be deemed and called sanitary inspectors.

Mr. John objected to the distinction between a senior and junior sanitary inspector, and moved that the section should apply to all sanitary inspectors. Sir Philip Magnus agreed with most of the amendments suggested by Mr. John, but said that it was . . . if the bill was to go through, that the promoters should make concessions to those authorities which some years before bought their freedom by refusing to accept any grants from the Government. That was why the application of this bill was limited both as regards medical officers of health and sanitary inspectors. It was better to have four-fifths of a loaf than no bread. Mr. John, in the circumstances, withdrew his objection, and the bill was read a third time.

The Dentists Bill.

THE Dentists Bill, introduced by the Minister of Health to give effect to the recommendations of the Departmental Committee on the Dentists Act, 1878, was taken in Grand Committee of the House of Commons on June 7th, under the chairmanship of Mr. Turtton. The provisions were summarized in the *BRITISH MEDICAL JOURNAL* of May 14th, p. 715.

The principal discussion in Grand Committee was as to the future position of dentists at present unregistered as provided for in the bill. Under Clause 1 of the measure, which is to take effect not earlier than one year nor later than three years from the commencement of the Act, "the practice of dentistry by unregistered dentists is to be prohibited." But existing unregistered dentists are to be given the right of admission to the register, subject to evidence of good character, if they satisfy the Dental Board (to be set up) that they have for five years out of seven immediately preceding the commencement of the Act been engaged in the practice of dentistry as their main means of livelihood, or for one year before the commencement of the Act have been members of the Incorporated Dental Society. Existing unregistered dentists who have been in practice less than five years will be required to pass an examination before admission to the register. The Board is to have dispensing power to deal with cases of persons who cannot meet the requirements of the bill by reason of military service.

Dr. Fremantle, on behalf of the British Dental Association, moved an amendment to the Admission Clause (III) to the effect that the unregistered dentists who were to be admitted as registered dentists should be placed on a separate list. His argument was that there should be some discrimination between those who had been fully trained and qualified and those who were to be registered but had not previously so qualified. This was opposed by Colonel Wedgwood and Mr. Seddon.

Sir Alfred Mond (Minister of Health) said he did not like the idea of anything suggesting a separation of sheep and goats. If the amendment were passed it would have the effect of not registering dentists whom it was intended to benefit. For that reason he could not accept it. The amendment would, indeed, wreck the measure, as it would cut to the foundations of the scheme. Earlier in the session he had refused to introduce the bill because he had understood that it was controversial, but, subject to there being a general agreement amongst those concerned, he had announced he was willing to go forward with it. Otherwise he could not do so, as the Government time was so limited.

Dr. Fremantle said he had no desire to imperil the bill, neither had the British Dental Association. He withdrew his amendment.

Mr. Seddon afterwards moved that members of the National Dental Association and the Chemists' Dental Society should be given the same right of admission to registration as were to be conceded to the Incorporated Dental Society—namely, that the membership for one year before the commencement of the Act should qualify for registration. He urged that the National Dental Association had been very effective. Its members were not floating from village to village or town to town, but had permanent residence in their districts.

Mr. Alfred Mond, who was chairman of the Departmental Committee, opposed the inclusion of the National Dental Association in the provision. He did so because the witness who attended the departmental inquiry on their behalf had omitted to sign his evidence for publication. Mr. Harbison, for the Chemists' Dental Society, said they were prepared to accept the bill as it stood, and did not desire special inclusion.

The amendment was negatived by 26 votes to 6. The bill, after some further discussion, was passed to be reported to the House.

Ministry of Health: Reorganization.—Sir A. Mond, in answer to Sir S. Hoare, on June 2nd, said that the reorganization scheme of the Ministry of Health was not yet in operation. Throughout the public service, supervising assistant clerks had been assimilated into the higher clerical class, intermediate clerks into the executive class, and first class women clerks into the clerical class. The question of the transfer of any of the first class women clerks to the executive class or the higher clerical class would be considered when the number of such posts arising out of the pending reorganization was known.

Pension Patients in Mental Hospitals.—Mr. John Davison asked the Minister of Pensions, on May 31st, whether in any of the mental hospitals under his control methods of treatment advised by medical officers had been withheld from patients, and, if so, on what grounds; whether schemes of employment suitable for patients were in operation in these hospitals, and, if not, whether such schemes would be instituted. Mr. Macpherson replied that he had no knowledge of any instances in which treatment advised by responsible medical officers had been withheld from patients in hospitals under the control of his department for the treatment of neurasthenia and other mental disorders which were not certifiable under the Lunacy Acts. In the majority of these institutions suitable occupational treatment had already been provided, and it was hoped that it might be found possible to extend the arrangement for the remainder.

VOLUNTARY HOSPITALS COMMITTEE.

THE Voluntary Hospitals Committee, over which Viscount Cave presided, was appointed on January 25th "to consider the present financial position of the voluntary hospitals and to make recommendations as to any action which should be taken to assist them." The members of the Committee were Lord Linlithgow, Sir Clarendon Hyde, Sir W. B. Peat, Mr. Vernon Hartshorn, M.P., and Mr. R. C. Norman. The Committee has now completed its report, of which we are enabled to give the following preliminary account.

The report points out that the present financial difficulties of the hospitals are due to the war. The receipts from voluntary subscriptions, donations, and legacies have not fallen off—they have, on the contrary, risen by 67 per cent. since 1913—but during the war the cost of provisions, drugs, dressings, fuel, and labour increased to such an extent that the expenditure of the hospitals has increased by 138 per cent. since 1913. The aggregate deficits of all the voluntary hospitals of Great Britain for the present year are estimated at £1,000,000.

The Committee recognizes that the voluntary system is temporarily in jeopardy, and asks, "Is the voluntary system worth saving?" The answer is, "We are convinced that it is." Apart from the immense sum of voluntary subscriptions and donations (estimated at £3,000,000 a year), the voluntary system secures gratuitous and skilled service, both lay and medical, of inestimable value. It preserves freedom in medicine, and is of inestimable value to the welfare of the sick, the training of the medical profession, and the progress of medical research. The breakdown of the voluntary system would imperil these services and impose a constantly growing charge upon public funds.

It will be remembered that the Committee issued an interim report in March,¹ in the course of which it stated that the evidence already received had convinced it that it was desirable, in the public interest, to maintain the voluntary system of hospital management, and also that, mainly owing to the large increase during and since the war of salaries and wages, and the cost of provisions and materials, the hospitals were faced with a serious deficiency of income to meet the necessary expenditure. The interim report recommended as a pressing matter that the schemes to be approved for the distribution of the surplus disclosed at the quinquennial valuation of approved societies under the National Insurance Acts, should provide for the application of a substantial part of the surplus in making a contribution towards the cost of the maintenance of members of the societies in hospitals. This was recommended in the interests both of the hospitals and of the societies.

The Committee now expresses the opinion that if the voluntary hospitals are to be saved immediate assistance

must be given by the State, such assistance to be strictly limited to a definite period of two years, and to be given only to hospitals which show that they are taking all possible steps to re-establish their financial position. A grant so limited and conditioned would re-establish the hospitals in the self-supporting position which they occupied before the war, and would not be inconsistent with the maintenance of the voluntary system.

The Committee draws attention to a number of steps which managers of voluntary hospitals can themselves take to improve the financial position of the hospitals under their charge—for example, review of expenditure, particularly in the light of comparative costs which could be ascertained by the general adoption of a uniform system of accounts; co-operative buying of drugs, apparatus, stores, and some kinds of provisions; removal of convalescent cases to auxiliary hospitals; co-ordination of appeals for subscriptions; further development of new sources of income, such as subscriptions from wage earners and employers, and other contributory schemes, examples of which are quoted in the report; contributions from approved societies.

The following recommendations, if adopted, will require legislation or executive action:

1. That a Hospital Commission should be set up by the Minister of Health.
2. That Voluntary Hospitals Committees be formed in each county and county borough; the King Edward's Hospital Fund for London to perform the functions of a Voluntary Hospitals Committee for the Metropolitan Police District.
3. That Poor Law guardians be authorized to enter into arrangements as to the use of infirmaries.
4. That county councils be empowered to contribute to the expenses of Voluntary Hospitals Committees.
5. That failing the provision in the National Health Insurance Acts of a "hospital benefit," the Courts be authorized to award to hospitals compensation under the Employers' Liability and Workmen's Compensation Acts.
6. That local authorities be authorized to pay the cost of the treatment in hospitals of persons in their employ.
7. That the payment out of technical education funds of grants for the training of nurses be considered.
8. That provision be made for obtaining and tabulating returns of cases treated in hospitals.
9. That all contributions by employers to hospital funds be allowed as deductions from profits for income tax purposes.
10. That where the payment to a hospital of a testamentary gift of residue is delayed for more than a year, the hospital be authorized to claim repayment of income tax.

11. That legacy and succession duty on testamentary gifts to hospitals be remitted.

12. That Parliament be asked to sanction a temporary grant of £1,000,000 to be expended under the direction of the Hospitals Commission in the assistance of hospitals which require it.

13. That the Hospitals Commission be authorized during a period of two years to recommend grants for the extension and improvement of hospitals, subject to like contributions being made from private sources.

The intention would appear to be that the Hospital Commission should consist of the ablest workers in various leading organizations, philanthropic and medical, that have been identified with hospital services. It is proposed that the Hospital Committee to be set up for each county council, county borough or other area as may be desirable, for arranging as to organization, shall consist of not less than nine persons; in London advantage will be taken of the existence of King Edward's Fund to entrust the work to the Committee of that body.

The intention of the proposal to empower county councils to contribute towards the expenses of Voluntary Hospitals Committees is that county councils should become one of a number of new sources of support for hospitals.

The recommendation in paragraph 3 above, that the Poor Law guardians should be authorized to enter into arrangements as to the use of infirmaries, has reference to the utilization of vacant beds, but does not, we understand, imply any general taking over of the Poor Law infirmaries. The section of the report in which these matters are discussed is voluminous, and will require careful consideration.

England and Wales.

THE LEEDS DEPARTMENT OF PATHOLOGY.

IMPORTANT developments in the department of pathology of the University of Leeds have been steadily going on for a good many years, and some of the more important of them are of recent date. There was a time, and that not very long ago, when there was no definite connexion between the university and the infirmary in respect of pathological work. The autopsies were made by the assistant physicians, who of course afforded all facilities to the professor of pathology. Not only so, but Dr. Jacob and Dr. Trevelyan, who in succession held the position of professor of pathology, were themselves assistant physicians to the infirmary during a part of the time of their tenure of office. When Dr. Leyton was appointed professor, a rule was passed by the infirmary, on the recommendation of the faculty, which practically secured for the holder of the post a place within the walls of the infirmary, and as it was and is rather quaintly expressed in the rules of the infirmary, "Every candidate for the office of pathologist shall hold the position of professor of pathology and bacteriology in the University of Leeds." The members of the assistant staff continued to make autopsies, two days a week being allotted to the professor. It was regarded as a very valuable part of the duty of an assistant physician that some work of this kind should fall to his lot, and it was deemed desirable that a good many of the autopsies should be made by those who were fully in touch with clinical work. The clinical and pathological laboratory at the infirmary was under the charge of Dr. Matthew J. Stewart. During Dr. Leyton's tenure of office as professor of pathology at the university important changes were made, and under special arrangements a large amount of work was done for the Corporation of Leeds and for various centres in the rest of Yorkshire. When Dr. Leyton's regretted illness led to his resignation of the chair, Dr. Stewart was appointed by the council of the university as his successor. In harmony with the rule quoted above he was soon elected pathologist to the infirmary, and it was further arranged that, though the work in the *post-mortem* room was still to be done by several different members of the staff, Dr. Stewart should, as official pathologist to the infirmary, be responsible for the general supervision of the work in the clinical and pathological laboratories of the infirmary.

An arrangement has been entered into by the university, the infirmary and the Corporation of Leeds for the amalgamation of their various pathological interests. Professor Stewart is the responsible working head of this conjoint department, and there is an advisory committee representative of the three bodies, to which he submits an annual report. This report is before us. The staff includes, in addition to Professor Stewart, who is also "city bacteriologist," the lecturer in bacteriology, J. W. McLeod, O.B.E., M.B., Ch.B.; the lecturer in pathology, W. MacAdam, M.A., B.Sc., M.D., Ch.B., M.R.C.P., D.P.H.; the demonstrator in pathology, J. Gordon, M.B., Ch.B.; the demonstrator in bacteriology and public health, G. A. Wyon, B.Sc.Lond., M.D., Ch.B.Edin.; the demonstrators in pathology and bacteriology, H. H. Gleave, M.B., Ch.B.Leds., and H. V. Phelon, M.B., Ch.B.Leds.; and P. L. Sutherland, M.B., D.Sc., who is the lecturer on industrial diseases. There are also two honorary demonstrators in pathology—namely, Dr. Gruner and Mrs. Clara Stewart. The two honorary demonstrators in medical and surgical pathology are acting members of the assistant staff of the infirmary, and this arrangement is regarded as being very important and as securing that there shall be on the pathological staff men who are in daily touch with clinical work. They hold regular museum classes.

The report to which we have referred gives an admirable summary of the work carried out in the joint department. For the infirmary, 520 autopsies have been performed; 4,199 specimens (not including those from the venereal diseases department) have been examined; of these 2,321 were pathological and 1,878 were bacteriological. Dr. MacAdam is responsible, under Professor Stewart, for the work in the laboratories at the infirmary, where he is assisted by Dr. Gleave, and members of the honorary staff are pleased to have the valuable assistance of one who is a

trained chemical pathologist and a keen investigator. All the bacteriological work of the infirmary is carried out at the extension of the department of pathology, which is situated in St. George's House, adjoining the medical school, where Mr. McLeod, Mr. Wyon and Mr. Gordon act under the professor. The bacteriological work for the Public Health Department of the City of Leeds has been carried out in terms of the agreement with the Corporation, and 3,818 specimens have been examined. The work under the venereal diseases regulations has been carried out during the year for the boroughs of Leeds, Hull and Middlesbrough, and, for part of the year, for the City of York; altogether 11,406 specimens have been reported on. Some work has been done for the Ministry of Pensions. A further bond of union between the infirmary and the university is expressed in the conferring by the Board of the Infirmary of the titles of assistant bacteriologist and assistant pathologist on those who hold the lectureships on these subjects. It is pointed out that the pathological and bacteriological work is thus carried on in three places—namely, in the medical school of the university, in its extension in St. George's House and at the infirmary. It would be by no means a wise thing to work towards the complete concentration of the laboratory work either at the infirmary or at the university, but it would indeed be a great advance if, apart from the making of autopsies and those examinations which subserve a clinical purpose, all the work could be concentrated in one central institute, and this is what is in the minds of many who are far-seeing and hopeful.

LEEDS WORKPEOPLE'S HOSPITAL FUND.

The thirty-fourth annual report of the Leeds Workpeople's Hospital Fund presents many gratifying features. The total income from all sources during the year 1920 was £39,739, which is an increase of nearly £14,000 over the year 1919. The main source of income, and the most reliable, is the weekly collections from the various workshops in the city; they amounted to £23,505, which was £9,511 more than in 1919; this proves that the appeal to the workpeople to increase their weekly subscriptions has been largely responded to. Collections in public houses, school collections, competitions and other efforts, including the annual gala, make up the rest of the income. Carried over from 1919 was the sum of £1,995. From this total of about £41,000 grants were made to the various charitable institutions of the city. The General Infirmary received the handsome grant of £20,000, an increase of £10,000 over last year; the Leeds Public Dispensary received £3,000; the Hospital for Women £2,500; the Leeds Maternity Hospital £1,000; the District Nursing Association £800, and smaller institutions various sums from £200 to £50. The Fund also concerns itself with the support of convalescent homes; one of these is for men, and to it 785 patients were admitted during last year; two others for women are situated at Ilkley, and to these 539 patients were admitted. The benefits of these homes are confined to the subscribers to the Fund, and there is no doubt that the popularity of the Fund as a whole has been greatly enhanced by their institution, though, when it was begun, it appeared to some that the character of the organization was being somewhat altered from that which prevailed in the first instance, when the only object aimed at was the provision of money for the charitable institutions of the city.

BRISTOL UNIVERSITY.

As briefly announced in last week's JOURNAL, the University of Bristol has received with deep regret the announcement of the impending resignation of Sir Isambard Owen, M.D., the Vice-Chancellor. It will take effect at the end of the current year, owing to the new rules of the Treasury with regard to superannuation. Sir Isambard Owen, before he went to Bristol, had associations with the West, for he was born near Chepstow in Monmouthshire, and spent much of his boyhood at Gloucester. At the time when he was physician and lecturer in medicine at St. George's Hospital, he took a prominent part in the steps which led to the establishment of the University of Wales. In 1904 he gave up active practice to become Principal of Armstrong College, Newcastle-upon-Tyne. His experience in the reconstitution of the University of Durham proved of great value to him after his appointment in 1909 as Vice-Chancellor of Bristol

University. His powers of organization had full play at Bristol. During his twelve years' work in the internal administration of the university he has found time to promote in many ways the interests of the university and enlist for it public support in the wide area which it serves in the western counties.

INTERNATIONAL TUBERCULOSIS CONFERENCE IN LONDON.

An international conference on tuberculosis will be held in London at the Institution of Civil Engineers, Westminster, from July 26th to July 28th. The National Association for the Prevention of Tuberculosis, which represents Great Britain and Ireland on the Council of the International Union against Tuberculosis, has decided to merge its annual conference in the international meeting and will act as host. The International Union is the successor of the International Tuberculosis Conference which, down to 1913, assembled annually in one or other of the capitals of Europe or in America, and its purpose is to achieve an effective combination of the nations of the world against tuberculosis. The conference is open to members of the International Union against Tuberculosis and to official delegates from countries within the League of Nations and from the United States of America, and also to representatives from all authorities interested in the subject, to whom a fee of one guinea (to include a copy of the Transactions) is charged. The President of the International Union for the current year is M. Léon Bourgeois, President of the French Senate, who will be succeeded on the occasion of the conference in London by Professor Sir Robert Philip, of Edinburgh. The conference is to be welcomed to London on behalf of the Government by Lord Curzon of Kedleston and Sir Alfred Mond, Minister of Health. Addresses will be given at the opening meeting of the conference by M. Léon Bourgeois and Colonel George Bushnell, of the United States Army Medical Corps. The subjects for discussion include "The modes of diffusion of tuberculosis throughout the races of the world," to be opened by Professor Calmette, of the Pasteur Institute, Paris, and "The rôle of the medical profession in the prevention of tuberculosis," to be opened by Sir Humphry Rolleston, followed by Sir George Newman, Chief Medical Officer, Ministry of Health. The Lord Mayor of London will give a reception in honour of the International Union at the Mansion House on July 26th, and other social functions and visits to institutions of special interest are being arranged.

Scotland.

BELLAHOUSTON HOSPITAL.

It was mentioned last week that the Minister of Pensions had appointed a committee to inquire into the management of Bellahouston Hospital by the Ministry of Pensions and the Joint Disablement Committee for the South-West of Scotland. Questions upon the subject which have been put and answered in Parliament have been reported from time to time, but it will be interesting to summarize the position; for the following information we are indebted to the files of the *Glasgow Herald*.

The question at issue, it would appear, is one of the administration and indirectly of the efficiency of the outdoor department of Bellahouston Hospital, an institution maintained by the Ministry of Pensions. Its staff is paid by the Ministry; the indoor surgical and medical staff is drawn from physicians and surgeons, both senior and junior, who are on the staffs of the three large Glasgow voluntary hospitals, and these physicians and surgeons are men in the first rank in Glasgow. While the hospital is an institution belonging to the Ministry of Pensions it is nominally managed by the Joint (Disablement) Committee for the South-West of Scotland, composed of members elected by the Local War Pensions Committees, certain other organizations, and discharged men. This managing body has among its members many of the best known men in civil life in Glasgow, men who have occupied the highest position in municipal affairs: Sir Thomas Dunlop, G.B.E., Sir A. M'Innes Shaw, C.B., Sir John Samuel, K.B.E., and Sir Charles J. Cleland, chairman of the

Education Committee, who is chairman also of the above Committee.

The chairman of the committee alleged in the press that the Ministry of Pensions for some considerable time had been limiting the power of the committee until now it was wellnigh shorn of every vestige of authority. The dismissals, numbering as many as 900 outdoor patients, mentioned by Mr. Neil McLean, M.P., in his question addressed to the Ministry of Pensions on April 14th, came as a surprise to the committee, and were ordered without its knowledge or consent. The chairman stated in the press that the state of affairs which led to the dismissal of these pensioners was entirely due to the repeated refusals of the Ministry to act upon strong representations from the committee for an adequate medical and surgical staff in the out-patient department.

The Ministry replied on April 21st, pointing out that as long ago as September last instructions had been sent to Bellahouston that the entire medical staff of the hospital could be made available for out-patient as well as for in-patient treatment; the fact that these instructions were not carried out, necessitated the intervention of the Commissioner of Medical Services in December. The medical superintendent of the hospital, in consultation with the Commissioner of Medical Services, provided a remedy for the defective working of the out-patient department by making available the services of other members of the medical staff of the hospital for the examination and treatment of out-patients; the Minister went on to say that if the Joint Disablement Committee were ignorant of the alleged dismissals of the out-patients, then there was serious ground for anxiety as to the effectiveness of the supervision of the hospital exercised by the committee.

Sir Charles Cleland, on behalf of the committee, replied to the Ministry on April 26th. The reply is much too long to quote, and we can note one point only. Sir Charles Cleland asks: "Why, when the superintendent of the hospital proceeded to clear out the out-patient department, he did not obtain the services of some of the visiting staff instead of the services of the junior resident staff? . . . The position as regards the discharges from the out-patient department is that the newly appointed medical superintendent, with the aid of members of the junior staff, examined about 2,000 patients between February 5th and February 12th, and discharged about 953 as fit for work. Many of these cases were sent back to hospital on stretchers and in ambulances within 48 hours." This letter, dated April 26th, contains the names of 12 members of the committee who have intimated their resignation, and our information is that since the date of that letter, on April 28th, the Corporation of Glasgow appointed a committee to approach the Government to set up a public inquiry into the situation at Bellahouston Hospital, with the result mentioned last week that a committee of inquiry, with Lord Scott Dickson, Lord Justice-Clerk of Scotland, as chairman, has been appointed. It held its first meeting on June 6th. Since the resignation of members of the voluntary committee, Colonel Warden, Regional Director, Ministry of Pensions, has adopted means whereby the interests of the patients at Bellahouston will be looked after.

Ireland.

ROYAL VICTORIA HOSPITAL, BELFAST.

At the meeting of the board of management of the Royal Victoria Hospital, Belfast, on June 1st, the notification of the resignation, under the age limit rule, of Professor James A. Lindsay, M.D., F.R.C.P., senior physician, was received with great regret, and he was appointed to the consulting staff. Dr. J. E. MacIlwaine, senior out-patient physician, was elected to fill the vacancy, and an election for assistant physician will be held on June 15th. On the recommendation of the medical staff, Professor Lindsay will probably be asked to deliver clinical lectures at the hospital during the teaching session.

DR. F. B. POWER was recently presented at a meeting in Washington with a gold medal, to commemorate his services as director of the Wellcome Chemical Research Laboratories, London. The presentation was made by Mr. Henry S. Wellcome.

Correspondence.

CAPILLARY PRESSURE.

SIR,—I have read Dr. Leonard Hill's lecture on capillary pressure and oedema, published in your issue of May 28th, 1921, and am amazed that a man of his eminence could be guilty of so much fallacious reasoning through failing to take account of some elementary facts in physics.

In paragraph 2 he states his belief that the pressure of the brain against the skull is a measure of the pressure in the arterioles and capillaries within the brain; and in paragraph 3, that the pressure of the cerebro spinal fluid is the same as the above, and practically the same as the pressure in the cerebral veins. He might as well give the height of the barometer in a garden as a measure of the pressure in a hose-pipe at work in the garden.

When two portions of fluid are separated by a membrane on the stretch the pressures of the fluids at two opposed points are not equal unless the membrane have plane surfaces at the place. If the membrane be concave on one side and convex on the other—as, for example, in a soap bubble—the pressure on the concave side is greater than that on the convex side. With a given tension in the membrane, the smaller the radius of curvature of the curved surface the greater the difference of pressure on the two sides. When the curved surface has the form of a tube the inside pressure exceeds the outside pressure by $\frac{T}{R}$, where

T = the tension per unit of length tending to split the tube longitudinally, and
 R = the radius of the tube.

This may be expressed by the equation

$$p_1 - p_2 = \frac{T}{R},$$

p_1 and p_2 representing inside and outside pressures respectively.

Now the walls of capillaries are incapable of sustaining much tension; but, their radius being very small, about 0.000035 cm., a small tension can maintain a considerable difference of pressure between inside and outside. Thus, using c.g.s. units—

Let $p_1 - p_2$ = the pressure caused by 50 mm. of Hg.
 = 5×13.6 grams per sq. cm.
 = 68 grams per sq. cm.

Then $68 = \frac{T}{0.000035}$,

and $T = 0.00334$ grams per cm. of length.
 = 0.34 milligrams per cm. of length.

The maintenance of a considerable pressure in the capillaries, above that of the surrounding tissues, by a small tension in their walls, does not appear to have occurred to Dr. Hill. The walls of capillaries being so thin and collapsible, they are kept open only by having a higher pressure inside than outside. As they have no muscle cells in their wall, their diameter depends largely on this difference of pressure distending them more or less as the case may be.

Dr. Hill has also failed to take fully into account that the blood is not a simple fluid, but consists largely of corpuscles not much less in diameter than the capillaries. When he makes a slight increase in the outside pressure in his modification of the Roy and Brown apparatus described in paragraph 17, this causes a diminution of the tension in the capillary walls, resulting in a diminution of calibre, which causes a slowing of the current, although he may not have made the outside pressure anything like as great as the inside pressure, as he wrongly assumes he has done in paragraph 19. Even when he has increased the pressure so as to stop the flow of corpuscles through a capillary, he has probably not made the outside pressure equal to the inside pressure, but only reduced the calibre of the capillary to that of a corpuscle which then blocks it.

There are several other points in the lecture which I should like to criticize, particularly the explanations of certain phenomena in the eye given in paragraphs 5 and 6, but I fear you will think my letter already too long.—I am, etc.,

JOHN R. GILLESPIE, M.A., M.D.

Enock, Belfast, May 31st.

THE PREPARATION OF SCIENTIFIC PAPERS.

SIR,—I have received to day the JOURNAL of May 21st. Without waiting till my return home next week, I wish to thank mildly Dr. C. O. Hawthorne for his instructive criticism. To one who used to read his writings until driven off by his verbosity, it is very satisfactory to learn that he now intends to get rid of all superfluities.

"Should have found it necessary." Here the *it* is not redundant, but is essential to represent the thing which was necessary. There is a difference between having an independent opinion and having got one for an express purpose, though he does not seem to think so. Let him substitute idea, or any other appropriate word, and perhaps he will appreciate the difference. I have got a variety of paper fasteners, some very ordinary and others rather uncommon, but none with me on my journeyings, otherwise I might have sent him a sample.

I am obliged to him for looking up the double verification of the tower in Siloam. I am sorry he had not a much-needed dip in the pool. You may have a painting "in oils," or "in water colours," but an artist works with his brushes and a variety of paints. I must thank him for drawing attention to the split infinitive, an error into which I do not often tumble. To express strongly, which he suggests, implies the use of strong language, which is foreign to my nature, and certainly outside the vocabulary of a child. Another critic, who does not appear in print, suggests that I should have said, wished strongly. This would have been an egregious mistake, as I have no standard to measure the strength of my own wishes, and I would not attempt to gauge those of another. It would seem, therefore, that for accuracy of expression there is nothing left but either to break the rule of the grammarian or to omit, strongly. The little personal embellishments presented by this person, supercilious in appearance and in character, I can afford to ignore, especially as I am not living in a London fog. I have not followed his example, and so I have eschewed all repetition of his name, having found the personal pronoun quite sufficient.

I am very pleased to have this opportunity of pointing out an error in my letter which seems to have escaped the notice of others. I used the genitive singular, species, where I intended to use the nominative plural. I was using so many genitives that I suppose this one crept in inadvertently.—I am, etc.,

Dinard St. Enogat, June 3rd.

JAMES BARR.

THE PREVENTION OF PUERPERAL INFECTION.

SIR,—The discussion on this subject is of exceptional interest to the general practitioner, and ought to be of immense profit to him as well. The opinion of the general practitioner, who does the large proportion of the midwifery practice of the country, is surely of some value, but probably the most successful do not bother to express their opinions. I have attended a good number of cases—being at present well in the second thousand—under all sorts of conditions and with the assistance of all sorts of nurses. I have had trouble with sepsis, including one case of death from pyaemia, which I would not wish to occur to my worst enemy; it takes more out of a conscientious man than six months' ordinary work.

In my earlier cases I was all in favour of "leaving things to Nature," which counsel was given me by several shrewd practitioners of many years' standing. My later cases have been absolutely differently conducted, the principle being "get the labour finished as soon as possible." The latter I find the more successful by far, for it has most certainly not increased the morbidity, while at the same time it has won the gratitude and approval of the patients and their friends and saved me valuable time.

The one case of death from pyaemia was a 6 para. I never made a vaginal examination. I arrived in the room as the head was passing over the perineum; the placenta came away perfectly, and there was only a slight perineal laceration which I then considered not serious enough to require a stitch. From this case and others in which there has been a slight rise of temperature I am satisfied that perineal lacerations are the biggest factor in the production of sepsis; they get infected from the vulva, napkins, etc., and it is easy to see the danger of such infected wounds when there is the raw placental surface

at no great distance, and the interval is often bridged with blood clot. Iodoform and boracic powder should be freely used, and a vaginal douche given night and morning. My advice is: Watch the perineum, and even if you arrive when the confinement is completed, do not believe the nurse, but see for yourself that the perineum is all right, and your morbidity will decrease by 50 per cent.

The second point I wish to emphasize is this: the third stage should not be rushed. One should wait at least half an hour if there is no haemorrhage, and if gentle pressure will not expel the placenta it is much safer to wash carefully and remove it manually than to use excessive force, with the risk of leaving a piece behind or tearing off the membranes. These manipulations rarely cause trouble; for, first, special care is taken to wash both one's hands and the patient; and secondly, no one should think of leaving such a case without giving an intrauterine douche of several quarts of lysol solution, and leaving instructions for a vaginal douche to be given night and morning for several days at least.

Thirdly, in multiparae, when the first stage is passed, the pelvis normal, and the presentation straightforward, pituitrin $\frac{1}{2}$ to 1 c.cm. with chloroform is to be preferred to forceps. The results are most gratifying to all concerned, and no amount of academic reasoning will convince to the contrary the man who has used it with the necessary caution in any considerable number of cases. Pituitrin expels not only the baby and the placenta, but also blood clot; and when ergot is given after the third stage, an empty and well contracted uterus is the result.

On the other hand, if pituitrin is contraindicated—and it must not be used indiscriminately—why be afraid to use forceps? The second stage can often be terminated in a few minutes, and it is unnecessary to do more than to insert two fingers for about one inch into the vagina to apply the forceps successfully. It is criminal to use unsterilized forceps, and surely every man is taught how to wash up both himself and the patient and pass a catheter.

In a primipara one may sit for two hours or more watching the head bobbing into and out of the vagina, the perineum stretching a little more with each pain till, at the end of the long wait, the last pain gets the head through far enough to begin a tear of the perineum, which is so thinned out that it rips down to the rectum rapidly and the baby is born. It seems to me that this bobbing in and out of the head is as dangerous as the insertion of two aseptic fingers and along these the sterilized forceps, which need never touch hair or skin. And, I believe, with skill, the perineum will be saved as often with forceps as with natural termination.

The great point is not to leave things to Nature—which is quite out of date—but get the second stage over as painlessly as possible, provided that if forceps are used they are followed by thorough douching, preferably intra-uterine.

The cases in which the hand has been inserted are certainly not those most likely to go wrong. This is my experience and the experience of others with whom I have talked; the reason is that thorough douching has followed and aseptic precautions have been taken. The simple cases, where there has been no interference, go wrong far more frequently—the simple perineal laceration is overlooked, becomes septic, and leads to sepsis, and possibly septicaemia. But the douching must on no account be left to the nurse. I witnessed one "skilled" female push the basin of antiseptic up to the patient and proceed to syringe the lotion into the vagina, allowing it to return from the vagina into the basin! And still we are puzzled as to the cause of sepsis? The great trouble is, in fact, that many patients cannot afford to pay proper nurses. The vaseline on the patient's vulva indicates that the nurse has made at least one, if not a dozen, vaginal examinations before the doctor's arrival with his antiseptic. Further, I personally never like to attend a case with a midwife who is herself attending a number of other cases, for one is apt to leave too much to her, and, on the other hand, she is not so careful when a doctor is there to share responsibility and blame. This is why these cases do not do so well as when the midwife herself attends alone.

To sum up the points I wish to emphasize:

1. Get the second stage over as painlessly as possible. If the patient is not having morphine and hyoscine, pituitrin

may be used in suitable cases or forceps, provided always that the doctor himself follows the forceps immediately with thorough douching.

2. Do not rush the third stage; empty the uterus manually without hesitation, but follow this with a thorough intrauterine douche.

3. It is most important to take great care with all perineal lacerations; such lacerations precede a very large number of septic cases. The vagina should be douched before and after repair, and iodoform and boracic powder should be freely used.

Success in preventing puerperal sepsis does not await any new discovery, but depends on attention to well-known details, and I have been well repaid by attention to the above points.—I am, etc.,

Ilford, E., May 23rd.

N. BEATTIE, M.D.

SIR,—During the years 1913 to 1920, while in charge of a maternity hospital in India, I had considerable opportunities for studying the above subject. It is in the hope that my experience may be of some value to others that I venture to address you.

When taking over charge of this institution I found that sepsis was by far the commonest cause of death in the obstetric practice of the hospital, and this was not surprising, as the majority of cases had already been examined by untrained midwives of the barbaric caste before admission.

In combating this state of affairs, the introduction of gloves, a strict aseptic ritual, and the restriction of vaginal examination to complicated cases by a competent obstetrical medical officer, played their part. But there remained a certain number of infected cases which, in spite of an empty uterus, intrauterine douching, etc., ended fatally. In several such cases I removed the uterus, but only one of these recovered, and I came to the conclusion that by the time I could make up my mind that such a severe measure was necessary either the local infection had spread too far or the patient's infection had become too severe for there to be a reasonable chance of recovery. It is only necessary to examine a uterus so removed to be convinced of the futility of curetting an infected uterus.

At this time I had started using the Carrel-Dakin method in my general surgical wards for the treatment of infected wounds, and was very pleased with the results obtained. I decided to give the method a trial in cases of puerperal sepsis.

Method.

After trying various techniques, it was found that the solution could be best applied to the infected uterus by means of a rubber tube, the two ends of a suitably sized tube being attached to two arms of a Y-shaped glass tube, the distal three inches or so of the loop thus formed being perforated with numerous holes and placed in the uterus. The Y tube being of course outside the vagina, had its stem connected up by means of a rubber tube, with an irrigator containing Dakin's solution. The flow of the solution was controlled by a clip on the last tube. By releasing the clip about one ounce of solution was allowed to douche the interior of the uterus every hour night and day.

This treatment gave apparently excellent results, and during the last complete year it was used there was only one death from sepsis out of the thirteen deaths from all causes that occurred in the 433 cases of labour that were attended. This result was a very great improvement on all previous years' results, and, considering the large number of infected cases admitted, was very gratifying. The details of the treatment were ably carried out by my house-surgeon, Rai Sahib Shiva Rao M. Trasi, M.B., C.M.

With reference to Dr. Blair Bell's remarks on auto-infection, the only cases I have seen in which I would dare to entertain such a suggestion were two cases of infection in obstetrically normal, clean, unexamined cases suffering from influenza. These occurred during the great influenza epidemic. This disease I soon recognized to have a most grave bearing on the prognosis when occurring in those subject to premature or full-term labour.—I am, etc.,

C. BRODSKIN,

Major I.M.S., late M.O. in charge King Edward's Hospital, Secunderabad, Deccan.

Penmaenmawr, May 20th.

SIR.—Writing on the "prevention of puerperal infection" in your issue of May 23rd I notice one of your contributors denounces the use of gloves in midwifery. He gives the following three reasons:

1. "They diminish tactile sensibility." Now if the gloves are a good fit they cannot possibly hinder the perception of such gross anatomical landmarks and relations as the os, bag of membranes, fontanelles, cephalic sutures, prolapsed cord, or the proper engagement or otherwise of any foetal part in the pelvic brim.

2. "The hands are clumsily washed . . . the result is that the left hand still infected presses on the fingers of the right glove and they are fouled." Surely no one would ever dream of touching the fingers of a sterilized glove with a bare hand, however clean. If the glove after being boiled, say in a little bag for the purpose, is emptied into a basin containing a weak solution of lysol—the basin having been previously scrubbed with a boiled nailbrush and scalded out from a kettle—nothing is easier than catching hold of the wrist of the glove with the clean left hand and slipping the right hand in up to the fingers as far as it will go, keeping hand and glove under the surface of the solution. It will be still easier if a washed piece of soap is added to the lysol.

3. "It is considered unnecessary to dip the gloves in an antiseptic." Your correspondent goes on to state that as a consequence any infectious material about the vulva is carried into the vagina without any inhibitor. But how could the momentary contact of an infective organism with perchloride or biniodide of mercury inhibit its growth? And why should the use of gloves prevent anyone from previously cleansing the vulva area? No doubt many cases of sepsis occur where no vaginal examination has been made. But why should this fact make us do away with the use of gloves?

I agree with your correspondent that sterile aprons are dangerous. In a house where there is no help they will not long remain sterile, and are therefore liable to give a false sense of security.

Some time ago a writer in the *BRITISH MEDICAL JOURNAL* advocated palpation per rectum. I thought I would try this, and was astonished to find how much information can be obtained from this method. As no aseptic ritual is required, it can be done before the patient is washed up. One can always carry a few rubber finger stalls for this purpose to every confinement or threatened abortion. Another of your correspondents fears that an examination per rectum of a patient in labour, as a substitute for the classical "per vaginam," could only result in the instant dismissal of the accoucheur. Fortunately this has not yet been my experience.—I am, etc.,

Leeds, May 25th.

H. T. O'NEILL.

SIR.—From the statements made in your leading article and Dr. Blair Bell's paper published in the *BRITISH MEDICAL JOURNAL* of May 14th it would appear that the objects of the Midwives Act have not been attained. I have always deplored the folly of medical men in giving away their obstetric practice to the so-called qualified midwife. They ought to conduct as many of these cases as they possibly can and to take a pride in getting the best results possible. The more they attend the greater will be their experience and efficiency, and the greater will be their ability to distinguish between the varying degrees of the normal up to the abnormal pregnancy and confinement. Why the general practitioner should wish to avoid midwifery has always been a mystery to me. I am quite sure it will pay him to give his best attention to these cases, and if he will do so at the confinement, as well as during the puerperium, he will find that the present mortality will be greatly reduced.

Without observing all the minute details of the ritual advocated by some of your correspondents, my mortality from puerperal sepsis has been 0.6 per 1,000 of the 1,500 cases I have conducted—that is, one death, and this happened where the surroundings were much better than the average. I believe the latest mortality rate is 1.76 per 1,000, almost three times the number in my own practice. I have been quite as successful with lysol as with biniodide. One point I observe is not to dry my right hand after thoroughly washing and scrubbing it, and always to rinse it in antiseptic after and before each vaginal examination. Should I need to use my left hand

I rewash and scrub it first. I think it quite possible that infection may be conveyed by wiping one's hands on a clean (?) towel.

The present increasing attendance by midwives at confinements does not seem to decrease the mortality from puerperal sepsis; this object might be attained by every general practitioner making a speciality of obstetrics and not allowing any one but himself to make vaginal examinations where these are necessary. I think it quite likely that, where a certified midwife and a doctor both attend a case, the midwife may have contaminated the patient before the doctor has touched her.

There is something very mysterious about puerperal infection, especially considering the experience given in the letter by "Old Fashioned" in the *JOURNAL* of May 28th. It is a fact that most of my cases which have required the most manipulation have shown no signs of infection, while other more normal cases have not got on so well.—I am, etc.,

Bournemouth, May 25th.

J. M. LOVETT.

SIR.—Like other general practitioners, I have been more amused than wrought by Dr. Blair Bell's address and by your leading article thereupon. Our withers remain unwarmed. For myself, it is satisfying to find the views on this subject which I expressed in the *BRITISH MEDICAL JOURNAL* of December 18th, 1920, so strongly confirmed by the letters in the *JOURNAL* these last two weeks. In my article I stated that "cases of sepsis will occur . . . in which one will not be able to trace a cause . . . the pursuit of a technique which experience has shown to be adequate is enough." I know, from Dr. Bonrac's letter in the following issue, that such a view moves Harley Street, and moves also, apparently, Rodney Street to wrath; but, after all, it is the general practitioner who bears the brunt of midwifery practice, and whose opinion is most likely to be generally accepted. What would old Dr. Hutchinson of Liverpool have said to Dr. Blair Bell's "absolute necessities" after fifty-two years in general practice without a maternal death?—I am, etc.,

Harton, Cambridge, May 31st.

W. J. YOUNG.

SIR.—The prevention of puerperal fever is so vitally important that I may be praised for joining in the present discussion.

It is evident that until the public is further enlightened no practitioner may avoid internal examinations without losing practice. What is chiefly important in internal examinations is the size of the pelvis and the help in diagnosing presentations. Anyway there is no need to put the finger up into the uterine cavity or high in the cervix. The presenting part is felt through the anterior fornix. If no fingers were passed inside the cervix, and if no *post partum* douches were given except under hospital conditions, puerperal sepsis would diminish by half.—I am, etc.,

Wolverhampton, May 31st

FREDERICK EDGE.

REFRACTION WORK IN SCHOOL CHILDREN.

SIR.—As a refractionist of considerable experience I would like to add a word to the discussion on the relative merits of objective and subjective refraction work. During the last ten years I must have done 30,000 refractions, and I am prepared to maintain that if the objective work be done by the right methods and with sufficient care, in most cases (except myopia) any subjective test, except to find what visual acuity is obtained with the correct glass, is waste of time.

The following method, in most cases, will give the cylinder, with an error less than 0.25 D., frequently less than 0.12 D., and the axis as accurately as the frames will allow it to be read.

Taking a case of compound hypermetropic astigmatism, and using the plane mirror, I first correct the meridian of least hypermetropia with a sphere. Then I put in the frame with this sphere a + cylinder somewhat less than the total amount of the astigmatism. If the astigmatism were 4 D. I would use a + 5 D. cyl. I turn this until the bright band indicative of astigmatism running across the pupil lies directly in the axis of the cylinder. This can be done with great accuracy, and an error of 5 deg. will send the band round through 10 deg. or 15 deg. in the opposite direction. Holding smaller cylinders in

my hand I then neutralize the refractive amount of the astigmatism, and often in doing this I have to alter the lens that at first seemed to correct the error of least error.

With the correct glass in front of the eye there should be no trace of astigmatism. Adding -0.5 sph. the shadow should move with, equally in both meridians, and adding $+0.5$ sph. it should be reversed, or with the concave mirror it should still move with. Subtract the reciprocal of the distance at which you work and you have the correction.

In a difficult case I work the whole thing out again using a concave mirror, first correcting with a sphere the meridian of greatest hypermetropia and then the astigmatism with $-$ cylinders. The latter method should give the same prescription as the former, only transposed. If the refracting surfaces of the eye are regular the cylinder is obtained by this method with much greater accuracy than by any subjective method in the average school child. If there be much irregular astigmatism the results are uncertain, but those of subjective testing are equally uncertain in such cases.

I do not profess to get the sphere with the same accuracy, as one frequently finds that different spheres are required to correct the centre and the edge of the pupil. In a highish hypermetrope an error of a fraction of a diopetre in the sphere, provided the error be not over-corrected, is unimportant, but in a myope I like to see what sphere gives the best vision. I consider I can do without difficulty 10 cases in an hour, and more if they are easy ones.

Imperfect mydriasis makes objective testing difficult, but it makes subjective nearly valueless. I have found hyoscine a useful cycloplegic. It should be used in a $\frac{1}{4}$ per cent. solution in castor oil. The alkaloid, not the salt, should be employed, and a good hour should be allowed for its action. In some 10,000 cases I have seen no toxic effects, but have made one child delirious by using a 1 per cent. solution.

Messrs. C. W. Dixey have made me a retinoscopy mirror in which a plane and a suitable concave mirror can be used conveniently with no waste of time.—I am, etc.,

T. W. LETCHWORTH,

Assistant Surgeon, Royal Eye Hospital; Ophthalmic
Surgeon, Tottenham and Surrey Education

London, W.1, May 28th.

Committees.

SIR,—It might be of some value to others to add the experience of one who has worried to some mastery of the subject, though through many personal and admitted mistakes.

There can be little doubt about the best method of prescribing glasses for school children. It falls into three stages:

1. At the first interview the visual acuity of each eye and then both eyes is recorded, and a note made of any external defect. (In a public administrative scheme, especially in country districts, this step can form part of the original routine examination of the child and need not necessarily be made by the oculist.) Arrangements are then made for the application of a mydriatic.

2. At the second interview the eyes are fully under atropine, and the error of refraction is estimated by retinoscopy and any disease of media or fundus noted. The child is told to cease the application of the mydriatic.

3. At the third interview—about two weeks later—a subjective test, based on the retinoscopy finding, is attempted in children over 7 years of age.

Now it is true that in some cases this attempt at subjective testing proves time-wasting, or would prove so if persisted in. It is also admitted that sometimes the retinoscopy findings are given preference in contradiction to the child's statement, as when a vigorous hypermetrope will not accept any plus glass at all. But it is also true that in many cases subjective attempt not only checks one's own possibilities of error, but vastly improves the child's chance of a comfortable correction, especially in astigmatic cases, where it can often say whether the cylinder in the trial frame makes the letters "slant sideways" or not.

Again, the individual child's power of accommodation varies and should occasionally be allowed for. A healthy outdoor type of country lad does not always appreciate being relieved of all his ciliary effort. And here I join issue with the dogmatist. Not the objective test alone, nor the subjective, should be the final answer, nor need a full correction be always given, but the considered guidance of all factors should determine the final prescription. To rely on retinoscopy alone, however experienced—and I venture to add, however expert one may become—is in my opinion helping still further to augment the income of the thriving prescribing optician.

But such a two-staged routine takes time and patience, and, from a public administrative point of view, means money. I suspect that in some ophthalmic school schemes no administrative provision is made for the possibility even of a subjective test after the effects of the mydriatic have passed away.

This point—the opportunity and the attempt at a subjective test in children—should be an acknowledged necessity, and I agree with the opinions advanced by Dr. A. E. Larking in your issue of May 21st, p. 759.—I am, etc.,

C. ALSTON HUGHES, M.D.,
D.Ch.O.

Liverpool, May 29th.

SIR,—We read with great interest the letter of our old friend Dr. Blease (p. 792), and note that he considers both subjective and objective methods should be employed; that only about three cases an hour should be done, and that the doctor should do the frame fitting himself. We have such confidence in Dr. Blease's skill that one of us has always entrusted his own eyesight to his care, but we doubt whether his practical judgement is in this case worthy of his professional skill. Staffordshire has about the lowest rateable value per child of any county in England; funds are therefore strictly limited; we have approximately 10,000 children requiring refraction, including about 2,000 squints. We fail to see "how the goods can be delivered" on such idealistic lines. In this district the local education authority would discover that the best was the enemy of the good, and that common sense in matters medical was rare, and usually in inverse ratio to the degree of education.

We regret to note from Dr. Larking's letter that any education authority or medical officer of health feels competent to dictate the exact rate at which a responsible official should work. In Staffordshire we only endeavour to impress upon our staff that the problem is how to do most good to a hundred thousand children with one oculist and no immediate prospect of more. In these days of financial crisis we weaken our influence with the public by ignoring the economic side of medical questions. Moreover, it would be interesting to hear the earliest age at which the correspondents use and place value on the subjective tests. We have found it only occasionally of value in children of 12 years, but even in children of 13 years in cases of astigmatism most reliance has to be placed on retinoscopy, and our experience in refraction work is that in most cases a difference of 10 degrees, and sometimes even of 20 degrees, in the axis of a cylinder would not be elicited on testing. How often has one found that even emmetropic children with normal fundi will not read all they see!

If much time is spent over the examination the child becomes tired, and no reliable information is then obtainable; so that to examine only three children in one hour does not necessarily mean that the best results accrue, nor that work more quickly done means work inaccurately done.

By far the greatest number of cases referred to the school oculist are children under 12 years of age, so that he must usually rely solely on the retinoscopy. Hence we agree with Mr. Bishop Harman that subjective tests in school children are of little practical value, and that such refraction work should only be carried out by those who have had the necessary experience to judge what is best to help the child to derive most benefit from education.

Dr. Blease points out—and we agree with him—that no reliance can be placed on complete cycloplegia being obtained from the parents' use of atropine, and hence in Stafford county we arrange for the school nurse to insert the atropine at the clinic or the school.—We are, etc.,

A. G. WILKINS (Senior Medical Inspector) and
JAS. WILLIAMSON (County Oculist) for the County
of Stafford.

May 30th.

THE ORGANIZATION OF SCHOOL OPHTHALMIC WORK.

SIR,—Mr. Bishop Harman's lucid article (BRITISH MEDICAL JOURNAL, May 28th, 1921) on the organization of school ophthalmic work is both interesting and instructive. There is one aspect of school ophthalmic work the importance of which requires to be emphasized—namely, the connexion between school clinics and an eye hospital.

Mr. Harman points out that this is essential in order that difficult cases may be properly dealt with. I should like to remark that this is also necessary from the point of view of the oculist himself. The number and variety of ophthalmoscopic conditions to be seen in a school clinic are very small, retinoscopy occupying a very large proportion of the work. So also the number of external diseases is small, if one excludes chronic blepharitis and phlyctenular conjunctivitis. Again, there are no facilities in the school clinics for operating or seeing operations performed. In order, therefore, that the school oculist may be proficient in the practice of ophthalmology as a whole, he must have a wider field of activity than the school clinic. The school oculist, it seems to me, ought to be allowed to spend two afternoons a week in the clinic of an eye hospital. The most satisfactory arrangement seems to hold where the school oculist devotes his forenoons (two and a half hours for five days a week) to the school clinic, and spends his afternoons at an eye hospital and at private practice.—I am, etc.,

JAMES N. TOWNENT,
Ophthalmic Surgeon, Dumbartonshire
(Educated on Authority).

Glasgow, May 30th.

CELL ACTIVITY AND SPECIFIC DRUG ACTION.

Sir,—As a general practitioner I was much interested in Dr. S. E. White's letter on cell activity and specific drug action which appeared in your issue of May 7th. The search for the specific curative drug in any case of disease, acute or chronic, must ever remain the chief aim of applied therapeutics. The suggestion that the selection of a drug by means of a close comparison of all its known and recorded symptoms and effects, with the total symptomatology presented by the diseased patient, is the basis of homoeopathy. The homoeopathic physician believes that in so administering a drug he is administering a specific stimulus to curative tissue reaction. The letter might well have been written by a homoeopath; and I cannot see any material difference between the suggestions put forward by Dr. White and the principles by which homoeopaths have selected and do select their drugs.

To my mind a more important consideration is whether such a method of drug selection is possible, practicable, or worth while. It is possible because homoeopathy possesses a large and complete "symptom register" pertaining to many drugs. The symptoms so recorded have been elicited by the administration of each drug to large numbers of healthy people who were willing to be subjects of experiment, the drug being "pushed" in many instances till serious and poisonous effects were produced. The symptoms felt and the signs presented by each "prover" were carefully correlated and compared with those presented by other "provers," and symptoms doubtfully due to the drug were eliminated. Clinical use and experience, moreover, have still further established a true symptomatology, while the effects of criminal and accidental poisonings have extended our knowledge of drug effects beyond those possible in a "proving." The net result is that, for the main drugs at least, the "symptom register" is full and genuine.

It is practicable to use this method by carefully taking note of all the symptoms presented by the patient—that is, his total divergence from his own or the commonly accepted normal; and not only those particulars which would lead to a diagnosis of the disease he is suffering from. It is then necessary to compare this record with the already existing symptom registers referred to; and to choose therefrom the drug which most closely corresponds to it. The drug is then administered in a dose which must be sufficient to stimulate reaction but insufficient to add to the sufferings of the patient, who—if the choice of drug be correct—is hypersensitive to it. That it is the tissue reaction which cures, and not the drug directly, is suggested by the fact that a repetition of the dose before the first has exhausted itself is very likely to stop reaction altogether. This method of choosing a drug is obviously laborious and time-consuming to the novice, and frequently enough to the experienced homoeopath. The results, however, make it well worth while. At the worst they are as good as the physician could formerly get by using drugs in the ordinary manner; in most cases they are decidedly better, and in some they appear at first as little short of miraculous.

Cases that have resisted ordinary drug treatment can often be satisfactorily dealt with; and even those that one had considered hopeless remain hopeless no longer. All this only if the physician spare neither time nor trouble. There are no short cuts to success, and homoeopathy offers no royal road to the cure of the sick. What it does offer is the means to cure so long as the patient has tissues that are capable of curative reaction.—I am, etc.,

London, N., May 19th.

W. N. BAKER, M.B., Ch.B.

HEART-BLOCK.

Sir,—I do not think that a paper such as that of Dr. Wardrop Griffith (May 28th, p. 763) should be allowed to pass without criticism, and especially that part where he says "it is clear that the systolic plateau is dimpled by the drag of the contracting auricle." Is it the function of the auricle to "dimple," and if not, why in this particular case? Did Dr. Griffith take the cardiogram from the patient sitting up or lying down? Was the receiver one inch or three inches in diameter? A reference to my article in the February number of the *Practitioner*, on "The pericardial factor in heart disease," will show that a great deal depends on the position of the patient and the size of the receiver, and that what may be a "dimple" in one position may be something quite different in another.

Apparently no consideration has been given in Dr. Griffith's cases to the quantity and quality of the pericardial fluid present; that they should be taken into account is proved by the fact that when the quantity is in excess, as in pericardial effusion, both waves and "dimples" disappear, whereas in toxic conditions the quality of the pericardial fluid varies with that of the other fluids of the body, and shows itself by an increased number of waves, due probably to a modification of the negative intracardial pressure.

His first case is stated to have died "without any obvious (sic) cardiac symptoms": possibly something abdominal was the cause of death; yet, are not the pericardial conditions very often disturbed in abdominal and especially peritonitic affections? The cardiac tracing in Fig. 5 is, in my opinion, one that suggests a toxic condition, and the fact that the heart conditions improved towards the end tends to confirm it.—I am, etc.,

Bransea, May 30th

G. ARBOUR STEPHENS.

THE "MEDICAL DIRECTORY, 1922."

Sir,—We beg leave to inform you that the annual circular has been posted to every member of the profession. We shall be grateful for its early return to us. If any practitioner fails to receive the form we will, upon request, send him a duplicate.—We are, etc.,

THE EDITORS OF THE "MEDICAL DIRECTORY,"
7, Great Marlborough Street, London, W.1.
June 4th.

Obituary.

SAMUEL THOMAS KNAGGS, M.D., F.R.C.S.I.,
Sydney.

WE regret to record the death, on April 13th, of Dr. Samuel Thomas Knaggs, who, until his retirement seven years ago, was one of the leading medical men of New South Wales. He was born in Ireland in 1842, and was brought by his father to Newcastle, Australia, six years later, and there he went to school. He returned to Dublin to study medicine, and in 1870 he obtained the diplomas of L.R.C.P.I. and L.R.C.S.I., passing his Fellowship examination and also graduating in medicine and surgery at Aberdeen University in the following year. In 1873, after he had returned to Australia, he obtained the degree of M.D. Aberd. He became one of the best known general practitioners in New South Wales, was honorary surgeon to the Newcastle Hospital, joined the New South Wales naval forces, attaining the rank of fleet surgeon, and received the Victorian Decoration. In 1875 he became editor of the *New South Wales Medical Gazette*, which, however, ceased publication six months later. Attracted by medical journalism, Dr. Knaggs two years afterwards started his own medical journal, *The Australian Practitioner*, which was admirably edited and had a considerable effect on the public

health activities of that time in the colony; but the business side was unsuccessful and publication eventually ceased. After twelve years' practice in Newcastle Dr. Knaggs went to Sydney, where he again began in general practice. His reputation had preceded him, however, and he soon became honorary surgeon at the Royal Prince Alfred Hospital, lecturer in clinical surgery at the University of Sydney, and examiner in anatomy and physiology to the Board of Technical Education. Later he accepted the position of medical officer of the Education Department, and afterwards was a member of the Board of Health of New South Wales; he was also appointed honorary surgeon to St. Vincent's Hospital, Sydney. His interests in the affairs of the New South Wales Branch of the British Medical Association dated from the very beginning of the Branch, and in 1886 he was chosen to fill the position of President. In 1895 the Branch acquired by purchase *The Australian Medical Gazette*, which had been established fourteen years before, and the first issue under the new management appeared in January, 1895, with Dr. Knaggs and Dr. L. R. Huxtable as editors. Dr. Huxtable died in July of the same year, and Dr. Knaggs continued as responsible editor until 1901. The six volumes of the *Gazette* during his period as editor stand as unassailable evidence of his ability as a medical journalist. After he relinquished the editorship of the *Gazette* he made a voyage to the East, and practised for some time in Kobe, Japan; on his return to Sydney he practically retired from private practice, and for the last seven years had lived in absolute retirement.

Dr. W. H. Crago writes in *The Medical Journal of Australia*: After an acquaintanceship with the late Dr. S. T. Knaggs, extending over forty-five years, I would like to add my tribute to his memory. Dr. Knaggs was a man of the most genial disposition, large-hearted and generous to a fault. As a friend he was loyal and incapable of doing anything mean. Nothing was too much trouble to him when he could do a kindly act to assist a friend or one in need of help. His advice and practical assistance were readily given to the younger men in the profession. It may truly be said of him that he upheld the best traditions of the profession in doing to others what he would that they should do to him.

ALEXANDER ROSE MACLEAY, M.B., C.M.EDIN.,

Honorary Physician, Bootle Borough Hospital.

DR. ALEXANDER R. MACLEAY died suddenly, from heart failure following operation, on May 29th. Born in Inverness, he graduated at the University of Edinburgh in 1887, and after holding residential appointments at the Infirmary, Inverness, and at the Eye Infirmary, Newcastle-on-Tyne, he settled down in practice in Bootle some thirty years ago. Dr. Macleay had a large practice in Bootle and surrounding district, and was one of the foremost practitioners in the town. Pains-taking and keeping himself thoroughly abreast of the times in scientific medicine, Dr. Macleay was appointed one of the honorary physicians to the Bootle Borough Hospital. His keen interest in his profession precluded him from taking any active part in public life. Yet his interests in everything that pertained to the well-being of the community were very close, and his support, quietly and unostentatiously bestowed, was known to many of his fellow townsmen. His outlook on life and its varied problems was that of a philosopher as well as a medical man. His sudden death came as a shock to many of his friends who were unaware of his illness; of a quiet disposition and somewhat reserved, he disliked to draw attention to himself. Indeed, it may be said that Dr. Macleay went about his daily work doing good, realizing that such a life brought its own reward. It was this characteristic that brought him such genuine affection from rich and poor alike.

The funeral took place at Sefton on June 1st; a large number of mourners, including many medical men, were present to pay a last tribute of affection to the memory of one who had so truly earned the esteem of all with whom he came into contact. He leaves a widow, for whom much sympathy will be felt. The memory of a good and conscientious medical man will remain long in the minds of his patients, who realize how good a friend Dr. Macleay was to them.

SURESH PRASAD SARBADHIKARI, B.A., M.D., C.I.E.,

Professor of Clinical Surgery, Carmichael Medical College, Calcutta.

DR. SURESH PRASAD SARBADHIKARI, one of the most eminent Indian surgeons, died on March 10th, 1921, in his 55th year. The son of a well known physician of Calcutta, he was educated at the Calcutta Medical College, and graduated M.B. of Calcutta University in 1888, and M.D. two years later. After serving for two years as house-surgeon at the Mayo Hospital, Calcutta, he went into private practice and quickly made a name as a surgeon, being one of the pioneers of ovariectomy in India. He was a vice-president of the first Indian Medical Congress in 1894, and was one of the Indian representatives at the International Medical Congress in London. A member of the Calcutta University Senate, he was a university examiner in surgery, and professor of clinical surgery at the Carmichael College. During the war Dr. Sarbadhikari organized the Bengal Ambulance Corps, which did good work in Mesopotamia; he was awarded the C.I.E., and was appointed an honorary lieutenant-colonel in the I.M.S. He had a large share in the establishment of Carmichael Medical College; he was a member of the British Medical Association, and did much to raise the status of Bengali medical men.

We regret to record the sudden death of Dr. WILLIAM ADAM SMITH MICHIE on May 11th. Dr. Michie, who was 69 years of age, was born at Towie, Aberdeenshire, and received his medical education at Aberdeen University, where he graduated M.B., C.M. in 1879, and M.D. in 1885. He subsequently took the diploma of M.R.C.S. Eng. After practising for some time near Aberdeen, he acquired a large general practice in Blackheath Road, Greenwich, and remained there until 1905. Thereafter he went into practice at 15e, Gower Street, where he worked with increasing success until the day of his death. Dr. Michie was an old member of the British Medical Association. His funeral was attended by many patients and by a detachment of the Metropolitan Police, many of whom he attended and with whom he was a great favourite. He is survived by his widow and two married daughters.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on June 4th C. G. L. Wolf, M.D., received the degree of Ph.D., and the following medical degrees were conferred:

M.D.—C. S. Clarke, L. M. Weeks.
M.B., B.Ch.—H. Barbash, L. W. Batten.
B.Ch.—W. H. Marshall.

Diploma in Psychological Medicine.—The dates for the next examinations have been fixed as follows: For Part I (Anatomy and Physiology of the Nervous System and Psychology), October 11th, 12th, and 13th, 1921; for Part II (Neurology and Psychiatry), November 30th, December 1st and 2nd, 1921. A course of instruction for the Diploma will be held in Cambridge from July 18th to August 20th. Lectures and practical work will be given by Dr. Lowson (Psychology), Dr. Thacker (Anatomy and Physiology of the Nervous System), Dr. Prideaux and Dr. Myers (Psychopathology), Dr. Rivers (Psychology and Pathology of Dreams), Dr. Archdale (Mental Diseases). Those who wish to take the course are requested to send their names, if possible before July 10th, to the Secretary of the D.P.M. Committee, Psychological Laboratory, Cambridge, from whom further particulars may be obtained.

UNIVERSITY OF MANCHESTER.

The following awards have been made:—Tom Jones Exhibition in Anatomy: L. J. Prosser. Turner Medical Prize: G. V. Ashcroft and Margaret Single.

PROFESSOR ACHARD has been elected general secretary of the Académie de Médecine.

At Bordeaux a post-graduate course in oto-rhino-laryngology will be held, under the direction of Professor Moure, from July 18th to 30th. The fee is 150 francs, and particulars may be had from the Secretary of the Faculty of Medicine, Place de la Victoire, Bordeaux.

PROFESSOR ALBU, a well known Berlin specialist on diseases of the stomach, died recently at the age of 54.

Medical News.

H.R.H. THE DUKE OF CONNAUGHT will distribute the prizes at St. Thomas's Hospital Medical School on Tuesday, June 21st, at 3 p.m., in the Governors' Hall.

A PROVINCIAL meeting of the Section of Diseases in Children of the Royal Society of Medicine will be held at Reading on June 24th and 25th.

A SYSTEMATIC post-graduate course of instruction in diseases of the heart will be held at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, from July 11th to July 23rd. Practical instruction will be given in the use of the polygraph, electro cardiograph and other instruments. Further information can be obtained from the secretary at the hospital.

AT the meeting of the Röntgen Society to be held at 35, Russell Square, W.C., on June 16th, at 8.15 p.m., there will be a discussion on the physics of the x-ray tube. All interested are invited to attend.

A DINING club, composed of all past and present members of the honorary and house staffs of the Hospital for Sick Children, Great Ormond Street, held its first dinner, under the chairmanship of Sir Thomas Barlow, on June 1st, when sixty-three members attended, including many who were house officers of the hospital as far back as 1880-1890. It is hoped to hold the next annual dinner on the first Saturday in June, 1922.

THE tournament of the Medical Golfing Society will be held at Walton Heath on Thursday, June 16th. The medical golf championship, for which the *Lancet* has presented a cup, will be played; there will be play also for the Henry Morris challenge cup and the Medical Golfing Society's medal (for the best return under handicap). The annual subscription to the Medical Golfing Society is 5s., which should be paid to the honorary secretary and treasurer, Dr. Rolt Creasy, 36, Weymouth Street, London, W.1. Entries for the competition should be sent to him not later than Tuesday, June 14th.

THE annual dinner of the Indian Medical Service will be held at the Trocadero on Wednesday, June 15th, Major-General Sir R. Havelock Charles, G.C.V.O., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S.(ret.), 63, Addison Road, Kensington, W.14.

DR. T. G. GARRY, M.B.E. (Cairo), has been reappointed British Physician at Pistany (Pöstyén), Czechoslovakia, for the summer months. Pistany has natural hot peat baths which are used for various forms of arthritis, pelvic disorders in women, and cutaneous affections. The place is an hour's journey from Pressburg, the capital of the Czechoslovakian Republic. The railway arrangements, it is said, are working satisfactorily.

THE subject of acid-fast bacilli in relation to the prevention and cure of tuberculosis has of late occupied much space in the German medical press. The papers advocating or condemning Friedmann's turtle vaccine have become so numerous that Professor J. Schwalbe, editor of the *Deutsche medizinische Wochenschrift*, announces that to check this deluge he will in future publish only such papers as contribute something definitely new to the subject.

DR. J. H. DOUGLAS WEBSTER, honorary radiologist to the Manchester Ear Hospital, and radiologist to the Manchester Board of Guardians, has been appointed Honorary Physician-in-Charge of the Department of Physical Medicine at the Middlesex Hospital, London.

A MEMORIAL to the medical officers, pharmacists, and members of the Belgian Army Medical Corps who lost their lives in the war was inaugurated by the Minister of National Defence in the Leopold Park, Brussels, on May 29th.

THE annual dinner of the West London Medico-Chirurgical Society was held at the Hotel Great Central on June 2nd, with the President, Dr. Frederick J. McCann, in the chair. After the loyal toasts had been honoured, Mr. Aslett Baldwin proposed "The Imperial Forces," making special mention of the great work done during the war by the medical services. In his reply, Surgeon Vice-Admiral Sir Robert Hill, Medical Director-General R.N., expressed his pleasure at being once again among West London friends. Sir Norman Moore, President of the Royal College of Physicians, in proposing prosperity to the West London Medico-Chirurgical Society, said that his recollection of Charles Keetley, with whose name the society would always be associated, was that of a delightful companion and brave man. Passing from the beginnings of

science at Hammersmith in the days of Prince Rupert, Sir Norman Moore spoke of the origins and functions of the London medical societies, and the benefit that came to them and to medicine through healthy competition. The President, in responding, traced the continued success of the society to the spirit of energy and progress which had animated its officers, among whom the names of Keetley, Bidwell, and Alderton would ever be remembered with honour. The health of "Kindred Societies and Guests" was submitted by Dr. Arthur Saunders and replied to by Dr. G. de B. Turtle, and the toast of "The Chairman" was proposed in warm terms by Dr. Richard Lloyd.

MR. NORMAN GODFREY BENNETT, M.A., M.B., L.D.S., and Mr. MONTAGUE HOPKINSON, L.D.S., have been appointed to act as examiners in the entrance examination for the Royal Naval Dental Service.

AT a recent meeting of the National Baby Week Council a message from Queen Mary was read by Dr. Eric Pritchard, who was in the chair. The message expressed Her Majesty's interest in the forthcoming celebration in July of the fifth anniversary of the inauguration of Baby Week, and her sincere wishes for the successful continuance of the work. At the same meeting Dr. Mabyn Read, medical officer of health for Worcester, gave some statistics regarding the reduction of the infant mortality rate in that city from 145 per 1,000 births in 1900-4 to 67 per 1,000 in 1920. Dr. Leonard Hill pointed the moral of the smokeless atmosphere of London at the present time, the result of the non-use of coal as fuel, and made a strong appeal for the proper use of coal, in order that the health of the whole community, and not least that of the children, might be benefited. Professor Edgar Collis spoke of economy in health and industrial hygiene. To obtain a healthy nation the first essential was expenditure on healthy infants. Miss Eleanor Rathbone, who pleaded for the endowment of motherhood, pointed out that poverty and privation—when the mother was child-bearing and the children were young—had a most serious permanent effect on the health of the race.

AT a meeting of the College of Physicians of Philadelphia on May 23rd, Madame Curie presented to the College an apparatus designed and used by her in her earlier research work on measuring the radio activity of radium, and Dr. Robert Abbe of New York presented mementoes of Lister and of Pasteur in a special case for their permanent preservation.

A HANDSOME presentation was made on June 1st to Dr. J. W. Mullen, Superintendent of the Ladywell Sanatorium, Salford, to mark his completion of forty years' service as medical superintendent of the infectious diseases hospital, and also, by a coincidence, the celebration of his silver wedding. A pupil of the late Sir William Stokes, Dr. Mullen qualified in Dublin in 1877, and immediately afterwards became medical superintendent of the Dublin Small-pox Hospital in the midst of a serious epidemic of that disease. Coming to Salford he devoted his life with great success to the care of patients suffering from infectious diseases.

AN exhibition of x-ray photographs has just been opened at the house of the Royal Photographic Society, 35, Russell Square, W.C., under the auspices of the Röntgen Society. Comprising over 250 prints, it includes a number of notable examples from the French radiologists, which arrived by special aeroplane from Paris on the day before the exhibition opened. Of historic interest are the photographs of hands of celebrities taken in 1896 by Mr. A. Campbell Swinton. There is a series of sets of four prints produced by lay workers employed in the radiographic departments of hospitals, or as assistants to qualified radiographers, shown in competition for prizes offered by Dr. Robert Knox, President of the Röntgen Society. The exhibition will remain open daily during the whole of June, except Sundays, from 11 a.m. to 5 p.m., admission free.

THE second International Congress on the History of Medicine will be held in Paris, from July 1st to 5th, under the auspices of the Société Française d'Histoire de la Médecine, and will be presided over by Professors Jeanselme and Menetrier. The Congress will be opened by the inauguration of the new museum of medical history. The mornings will be occupied by such topics as the history of hospitals and public health work, identification of the great epidemics of history, and the food supply of man and beast in antiquity and the Middle Ages, while in the afternoons excursions will be made to various hospitals, museums, and other places of historical interest in and near Paris. Further details may be obtained from the secretary-general, Dr. Laignel-Lavastine, 12 bis, place de Laborde, 8, Paris.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Ailiology, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, Medisecra, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the JOURNAL is 16, South Frederick Street, Dublin; telephone, 4737, Dublin, and of Rutland Square, Edinburgh (telegrams: telephone, 4351, Central).

QUERIES AND ANSWERS.

"P. C. G." wishes to ascertain the value, if any, of a work on surgery, in Latin, by Iohannes Tagantins, printed at Leyden in 1560, and illustrated with woodcuts.

"WORRIED" writes: Can any of your readers kindly advise me as to the treatment of a case of *Oxyuris vermicularis* of three years' duration. Injections of salt and infusion of guassia by means of a long tube have been repeatedly and continuously tried without success.

"M." as the result of a strain of the right knee some years ago, is now liable, on any slight injury, to suffer aching under the patellar ligament. There is no evidence of rheumatism or known focus of infection. He asks whether it is due to a bursitis or to a "nipping" of the fat and synovial membrane under the ligament, and what is the best treatment?

INCOME TAX.

"C. P." inquires as to liability—if any—in respect of interest accruing in India, but not remitted to this country, on stocks belonging to his wife.

"*." If neither "C. P." nor his wife are ordinarily resident in this country the basis of liability is the amount remitted in the year of assessment; in the alternative liability attaches to the income accruing, whether it is remitted to this country or not. The rate payable is the full, or investment, rate.

"MEDICAL MISSIONARY" states that he receives as a foreign missionary "£260 a year tax free." In making a statement for the purpose of reclaiming a portion of the tax suffered on his private income, he asks how he should calculate the gross income.

"*." If the Missionary Society is specifically accounting for tax to the British income tax authorities on the stipend the amount to be added to the £260 is the sum paid to the authorities by the society. If, however, our correspondent means that the stipend is "tax free" in the sense that it is exempt from assessment to tax in this country—which seems to be the correct position—he should enter the income as "£260 not liable to taxation."

LETTERS, NOTES, ETC.

DIAPHRAGMATIC HERNIA.

DR. HUGH A. DAVIS, of Wimbledon, writes to say that he was recently called to make a necropsy on a newborn infant. The abdominal cavity contained only the liver, left kidney, bladder, and about one and a half inches of the lower bowel. The other abdominal organs were in the thorax tightly packed against the lungs, which were solid. The opening in the diaphragm was about one and a half inches in diameter.

PSYCHIC PHENOMENA.

DR. J. SCOTT BATTAMS (London, N.W.) writes: In your brief notice of Dr. Crawford's book, *The Psychic Structures of the Goligher Circle*, your reviewer suggests three possible attitudes that may be assumed in regard to this field of inquiry, choosing for himself the most common, and perhaps the least desirable

—namely, the sceptical attitude, with a strong bias towards explaining various phenomena as due to illusion of the senses, as in conjuring tricks. In this attitude of mind many who are now spiritualists began to investigate. It accounts probably for the conclusions reached by those who, without even such first-hand experience, ignore or belittle the remarkable investigations of Dr. Crawford and Dr. Geley. Your reviewer advocates investigation "even of spiritualistic phenomena," but kicks at the precautions and conditions demanded by mediums. But in this obscure field of research the methods of science may suffice, but its most delicate instruments are often useless, and it is impossible to lay down hard and fast conditions. They must be discovered by prolonged investigation and repeated experiment; and the true scientist will not ignore the precautions and conditions adopted by other explorers as the result of experience. To those of us who lack such first-hand experience the question of attitude becomes the more important. I express no opinion as to how far a materialistic science is compatible with any idealistic philosophy or spiritual religion, but it may safely be suggested that scientific men should approach the investigation of "so-called psychic phenomena" with the open mind, remembering that we have not reached that summit where there is no more to learn, but are all evolving. Orthodox psychology knows little of the "make-up" of the medium, and, though it has greatly enlarged our conception of the subconscious, yet to many it is a lumber-room and to others, apparently, a cesspool. Nor should we forget the chastening fact that at every advance in knowledge some of our most cherished theories and dogmas pass into oblivion.

"*." Our Reviewer writes: To Dr. Scott Battams's "attitude" towards other explorers no one need take exception; but his admission that the most delicate instruments of science are often useless in this field of research gives the reason why investigators should refrain from advancing hypothesis of pseudopods and mysterious emanations from the medium. Nearly all writers on the subject of mediums have admitted that the practice of deception has at times been detected. Surely such deception resembles an attempt at producing the illusions of the conjurer, who also demands "precautions and conditions." Therefore any research into the origin of the phenomena demands the attitude of mind adopted with regard to the manipulations of the conjurer, and such words as "materialization" and "pseudopods" should be eliminated from the discussion, unless, indeed, the direct attack has been made on the manifestations by seizing a pseudopod and subjecting it to examination. The allegation that such treatment might seriously damage the medium is given as a reason for imposing some of the conditions. We believe, however, that attempts made in this direction have had no disastrous effects. So long as such crucial tests are not made, the investigator should studiously refrain from suggesting explanations of the phenomena—or illusions—which he describes.

"THE BUFF BOOK."

DR. H. J. VAN PRAAGH (Hampstead, N.W.3) writes: I shall be obliged if you will kindly note that my name appears in "The Buff Book" without my knowledge or consent, and I have written to inform the publishers of their error. I have no idea how it got there, and quite agree with you that it is an unprofessional insertion.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 25, 26, 27, 30, 31, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 23, 29, and 30.

MESSRS. R. AND J. BECK, Ltd. (68, Cornhill, E.C.3), have issued a catalogue describing, with illustrations, special types of the Standard London Microscope. Copies may be obtained on application.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under ...	0	9	0
Each additional line ...	0	1	6
Whole single column (three columns to page) ...	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, at the General Post Office, not later than the first post on Tuesday morning. If not paid for at the time, should be

NOTE.—It is against the rules of the Post Office to receive post-
restants letters addressed either in initials or numbers.

HASSIN, STANGOL, and BAILEY (*Journ. Nervous and Mental Diseases*, March, 1921) point out that many cases of lethargic encephalitis may be clinically atypical, although perfectly typical pathologically. Notes of two cases are given, in neither of which were any of the typical signs present, and cal findings of the Sylvian aqueduct and the peduncles, the manifestations being principally involvement of the third nerve. This did not show as ptosis or other ocular extrinsic paralysis, but as an intrinsic paralysis in the form of sluggish or rigid pupils. In all cases, therefore, of suspected epidemic encephalitis the pupils should be carefully examined, since it is impossible to imagine the occurrence of such a widespread lesion of the mid-brain without some ocular manifestations being present.

FRANCIONI (*Il Policlinico, Sez. Prat.*, April 25th, 1921) describes a special syndrome which he has observed in about 20 children aged from 2 to 15 years, both sexes being equally represented. All the patients showed more or less pronounced psychological changes, there being either excessive irritability or violent behaviour, or, on the other hand, apathy and lassitude, changes in affectivity shown by indifference to their parents, and changes in their general appearance. The intellectual faculties, however, were not much affected, so that some of the children continued to attend school. Only a few of the patients showed more pronounced psychological symptoms, such as an exaggerated motor restlessness, motor and verbal stereotypy, tendency to lying, or fugues. The most important symptom, however, which was present in every case, was the occurrence of insomnia. It was first of all noted that the slight psychological changes mentioned became more pronounced towards evening. When the children were put to bed they were quite unable to go to sleep, but remained in a state of psychological and motor restlessness until the early morning. Francioni emphasizes the fact that the condition was not really a disturbance of sleep, because when once the children succeeded in getting to sleep the sleep was long, deep, and quiet. The other symptoms consisted in a moderate degree of loss of flesh, slight trophic changes in the skin and muscles, loss of appetite, vomiting, yawning, and sighing. The syndrome had a chronic course, and it was only after several months' observation that a slight improvement occurred. In some of the cases there was a history of a recent acute febrile disease with the characteristics of epidemic encephalitis, and Francioni thinks it probable that even where there was no such history the condition was due to the same cause, especially as most of his cases occurred at a time (January and February, 1920) when epidemic encephalitis was prevalent. He states that Fiore had seen four similar cases in children aged 3 to 12 years at the Florence Paediatric Clinic, and alludes to the recent paper by Roasenda (see *EPITOME*, April 9th, No. 433).

TURETINI and PIOTROWSKI (*Paris méd.*, April 30th, 1921) record a case of lethargic encephalitis in a woman, aged 24, in whom the disease lasted nine months. The symptoms consisted of obstinate drowsiness, followed by very marked hypertonus and trismus, which necessitated artificial feeding. The ocular symptoms were very slight. The writers have found only three similar cases on record—namely, two reported by Economo, in which the disease lasted two years and eight months respectively, and one by Ascoli. They remark that a very prolonged course is peculiar to the lethargic form, for it has never been observed in the myoclonic variety or other forms of epidemic encephalitis.

ACCORDING to PETIT (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, April 28th, 1921) the mental forms of epidemic encephalitis may assume a subacute, acute, or hyperacute course. Some cases are characterized by an abnormally

long course, which is sometimes interrupted by remissions or intermissions. Petit records three cases in which there persisted for more than a year, either continuously or with remissions or intermissions, various psychopathic syndromes, such as acute delirium, mental confusion, hallucinations, impulsions, and phobias, which were shown by the transient appearance of certain organic signs to be due to epidemic encephalitis.

GIBSON and MARTIN (*Archiv. Int. Méd.*, March 15th, 1921) studied experimentally the effects of lumbar puncture, pituitary extract, and histamin administration, the nitrogenous metabolism, the blood constituents, and the carbohydrate tolerance in a severe case of diabetes insipidus with chronic syphilis. Lumbar puncture did not relieve the symptoms, the polyuria being rather increased on the day of the puncture, and on the following day. Pituitary extract given subcutaneously increased for a time the concentration, and reduced the volume of the urine; histamin gave a similar though less effective result. On the day following the first pituitary extract injections, and on subsequent intervening non-pituitary days, a decrease in the polyuria with a relative increase in concentration was maintained. Decalcated whole pituitary substance, in four 3-grain doses orally, produced a slight immediate effect. A lower nitrogen elimination resulted from the pituitary extract injections, with diminished ammonia and a somewhat increased uric acid output. Glycogenesis was not reduced, and there was hypoglycaemia.

MINET (*Bull. de la Soc. Méd. de Paris*, February 10th, 1921) records three cases of asthma treated with autogenous vaccines (mostly made up of staphylococci, streptococci, and *Micrococcus tetragenus*). In the first case no certain result followed, but in the other two excellent results were obtained, and the patients expressed themselves as delighted. In each of these two cases the asthma was of long duration (in one case from infancy, in the other for fifteen years), and neither was able to work. Since treatment they were able to work. At first the injections made the patients worse, but after about eight or nine injections improvement set in, and the final results were surprisingly good.

BANG (*Norsk. Mag. for Lægevidenskaben*, March, 1921) discusses the genesis of "aseptic purulent meningitis" associated with uraemia. In one of his cases there were signs of chronic nephritis and uraemia; the blood pressure was raised (125-175 mm.) and the intraspinal pressure was much above normal. At the first lumbar puncture the cerebro-spinal fluid was perfectly clear. Next day it was very cloudy and contained numerous polymorphous leucocytes, but no microbes. The clinical picture was rather that of uraemia than meningitis. Thus, there was headache with vomiting, partial loss of consciousness, and urea retention, but the reflexes were unaffected, Kernig's sign was not demonstrable, and there was no cervical rigidity. In another case there were also signs of uraemia with coma; the cerebro-spinal fluid was purulent and blood-stained and no microbes could be found. The author admits that in neither of these cases was an attempt made to cultivate anaerobic microbes from the cerebro-spinal fluid, and he notes that the same omission has been made by other writers who have described similar cases. With such flaws in the bacteriological evidence, it may be that the purulent cerebro-spinal fluid in such cases has, after all, a septic, inflammatory origin. But at present it is not possible to dismiss as untenable the view that this condition of the cerebro-spinal fluid is due to an accumulation of urea in the system.

SCHÖNBAUER (*Wien. klin. Woch.*, February 17th, 1921) records a case of severe tetanus successfully treated by curare after failure of tetanus antitoxin. Subcutaneous injections were given, starting with 2 mg. and increased daily until the dose of 5 mg. had been reached. An attempt to raise the dose to 6 mg. led to transient paralysis of the respiratory muscles causing considerable dyspnoea, so that

the dose of 5 mg. was continued, and it was found that the convulsions, which sometimes occurred every hour, completely subsided after administration of curare. The injections were at first given daily at 7.30 a.m., and kept the patient free from attacks until about 4 p.m., when more or less violent convulsions began again. It was therefore decided to divide the dose, and from the tenth day 3 mg. were given in the morning and 3 mg. in the evening daily. After another five days the attacks were only caused by an unusually violent external stimulus, such as washing in cold water. The patient received 63 mg. of curare in all in the course of fourteen days.

675.

Intrathoracic Neoplasms.

FISHBERG and STEINBACH (*Med. Record*, March 26th, 1921), in discussing the diagnosis of intrathoracic neoplasms, consider that physical examination of the chest is more trustworthy than any other diagnostic method; they rely mainly upon the flat note elicited by percussion over the site of the tumour. Dyspnoea and pain in the chest are two early symptoms, as these rarely occur in early phthisis, and pulmonary neoplasm should be borne in mind when a patient at the cancer age begins to cough and is short-winded, while showing no signs of cardiac, renal, or arterial disease. The dyspnoea in cancer is due to the occlusion of a large bronchus either from within or from without, and when a primary bronchus is affected this may be very severe. Next to dyspnoea pain is a constant symptom, and its presence, with or without a pleural effusion, is suggestive. Fever may be present in some cases, making the differentiation from pulmonary tuberculosis difficult, but physical examination of the chest will generally settle the diagnosis. Enlargement of superficial glands in the neck between the heads of the sterno-mastoid, or in the axilla, is a late symptom, the tumour being by that time quite extensive and detectable. Enlargement of the superficial veins of the chest and shoulder is not common and occurs only in cases in which metastasis has occurred in the mediastinal glands. The flat note on percussion over the site of the tumour is more to be relied upon than radiography in diagnosis, the dull area, as a rule, being much more extensive than the size of the growth, so that even small tumours are more easily found by percussion and auscultation than by x-ray. Feeble or complete absence of breath sounds, or bronchial breathing, occur when a bronchus is blocked entirely or only partially. Nearly all laboratory aids to diagnosis, while in some cases confirmatory, in most are of no value or altogether misleading, and even radiography may prove misleading or negative. The presence of fluid often obscures a tumour, so that the fluid should be withdrawn and a pneumothorax produced if radiography is to be of use in such cases.

SURGERY.**676. Enterostomy for Post-operative Ileus.**

MÜLLER (*Hospitaltidende*, February 23rd and March 30th, 1921) emphasizes the difficulty of distinguishing between mechanical and dynamic intestinal obstruction within the first two weeks of an operation. In and after the third week intestinal obstruction is usually due to mechanical causes, whereas in the first fortnight this condition is often due to a combination of mechanical and dynamic causes. The author records eight cases of acute appendicitis in which he performed enterostomy for intestinal obstruction within eleven days of the original operation. In all these cases the intestinal obstruction had lasted for days, and mechanical and medicinal treatment had proved futile. Five of his patients recovered, and great relief was experienced by the other patients, who succumbed to general peritonitis in spite of this treatment. Discussing the dis-favour into which enterostomy for post-operative ileus fell some years ago, the author points out that much depends on the technique and not delaying the operation till the patient is moribund. With regard to the former point, he insists on the enterostomy opening being as small as possible. In some of his cases he punctured the gut with a Paquelin cautery, the opening being just large enough to admit a Pezzer catheter. He experienced no difficulties with the enterostomy wound, which invariably closed of itself within a few weeks. There were no subsequent mechanical complications, no formation of an artificial anus, and no disturbances from inanition. Though he admits that in theory the success of this operation may partly depend on the level at which the opening is made in the small intestine, he found in practice that it was best to puncture forthwith the most distended section of gut which presented itself on re-laparotomy.

850 B

677.

Retropharyngeal Abscess.

FRIEDMAN and GREENFIELD (*New York Med. Journ.*, April 20th, 1921), from an experience of 60 cases of acute primary retropharyngeal abscess, point out that early and adequate internal incision will ensure rapid and complete recovery in most instances, and they strongly advise against drainage through an external incision, even when the external swelling is extreme. In the authors' experience the condition occurs mostly within the first three years of life, the youngest being 21 days, though older children and adults may suffer, as shown by the oldest case being 20 years old. In the large majority of cases the condition is associated with diseased tonsils and adenoids, or purulent rhinitis. The most pronounced symptoms are those of obstruction in the pharynx, and, in infants, those due to pressure on the larynx, with fever, restlessness, hoarseness, and dyspnoea. The condition may be mistaken for acute tonsillitis, but palpation of the pharynx with the finger will reveal a fluctuating swelling, and such examination should always be made in infants presenting any cervical glandular enlargement, or with a rigid neck. In operating no anaesthetic is needed, and is generally inadvisable in a child whose respiratory channel is already impeded. With the patient tightly wrapped in a sheet, and held in the upright position by an assistant who steadies the head, a vertical incision is made into the mass with a curved bistoury, care being taken to reach the lowermost limit of the abscess cavity. Immediately after incision the child is lowered face downwards, and the pus allowed to drain away. Relief and complete recovery quickly follow, and in no instance was it necessary for the authors to repeat the operation. After-treatment consists in local cleanliness, tonics, and nourishing food.

678. Association of Tonsillar Chancre and Vincent's Angina.

SOUCHE (Rev. de lar., d'otol., et de rhinol., March 31st, 1921), after referring to the different appearances assumed by tonsillar chancre, especially the polypoid form described by Portmann (see EPITOME, April 24th, 1920, No. 449), emphasizes the difficulties of diagnosis when a tonsillar chancre is associated with Vincent's angina. He records a case in which the clinical and bacteriological appearances were those of Vincent's angina, and it was not until the appearance of an eruption on the face and scrotum that the presence of syphilis was suspected. Another examination then showed the presence of the *Spirochaeta pallida*, as well as the fusio-spirillar symbiosis characteristic of Vincent's angina, and a positive Wassermann reaction. Souchet emphasizes the dangers of a hasty and incomplete bacteriological examination in cases of persistent ulceromembranous tonsillitis, and recommends that in doubtful cases one should not be content with examination of a superficial scraping of the diphtheroid deposit covering the ulcer, but should examine the serous discharge which may show the presence of the *Spirochaeta pallida*.

679. X-Ray Treatment of Interstitial Keratitis.

JAPIOT and BUSSY (*Journ. de Radiol. et d'Électrol.*, March, 1921) state that though x-rays have never been systematically employed in the treatment of interstitial keratitis, there is no disease of the eye in which this method is more indicated, interstitial keratitis being a disease which is characterized, at least at the onset, by an infiltration into the layers of the cornea of young connective tissue cells, susceptible to the action of x-rays, and without severe lesions in the cornea or marked changes in its structure. In order to be successful x-ray treatment must be employed during the period of infiltration before deep lesions of the cornea have given rise to indelible scars. The younger the patient and the greater the infiltration the more favourable the results, the greatest benefit being obtained in cases due to inherited syphilis. The method consists in irradiation of the closed eye with very small doses, without special protection or localization. In most cases five applications with a week's interval between each are sufficient, the duration of each application being five minutes. The irradiation probably acts not by destroying the cells but by mobilizing them, the action being similar to that which occurs in adenitis, splenomegaly, and sciatitis. The method does not damage the lids or the ocular membranes, or arrest the development of the lens. It is quite painless, and does not require any fixation of the eye. It should be added to and not replace the usual treatment for interstitial keratitis, such as atropine, dionine, yellow ointment, mercury, and iodides. It produces a very rapid relief of pain, photophobia, and blepharospasm, shortens considerably the course of the disease, and if employed in time causes an absorption of the infiltration better than any other method.

630. Diverticula of the Urinary Bladder.

SCRO (Canadian Med. Assoc. Journ., April, 1921) considers that congenital deformity or lack of development is an etiological factor in all cases of diverticula of the urinary bladder. Occurring chiefly in males over 50 years of age, the symptoms vary with the presence or absence of infection. A characteristic subjective symptom is a feeling that the bladder does not empty itself, causing a frequent desire to urinate. A suggestive symptom is difficulty in starting the stream, which flows freely when once started. Pain is variable, and is apparently due to the degree of distension of the diverticula. Pus is usually present, and it is suggestive of this condition if, during bladder washings, some are quite clear while others contain pus. Cystoscopic examination clears up the diagnosis, and the extent of the diverticulum may be ascertained by x-ray examination after passing an opaque ureteral catheter through the cystoscope when it can be seen coiled up in the diverticulum. Treatment consists in complete separation and removal of the sac at its neck through the suprapubic extraperitoneal route. When the entire sac is isolated it should be inverted into the bladder, the neck trans-fixed and ligated intravesically, and the remainder incised, the deficiency in the muscular wall of the bladder being closed by continuous suture. Multiple diverticula are dealt with in the same way.

631. The Characteristics of Appendicitis in Old Age.

PAUS (Norsk Mag. for Laegevidenskab, April, 1921) notes that appendicitis is commonly regarded as a disease of comparatively early life, and that in older patients there is nearly always a history of attacks of abdominal pain since childhood. Most of the serious acute cases develop before the age of 50, but there is a small class in which the disease does not flare up till old age and in which there is no record of previous attacks. In one year alone he has seen five cases of acute appendicitis in patients over 50, and in several respects these cases differed much from the typical appendicitis of youth and middle life. In senile appendicitis there is a tendency for perforation to occur early—often within a few hours of the onset of the symptoms. The general symptoms are largely obscured by the local symptoms, which are comparatively prominent. Thus, there is little or no rise of temperature, the pulse remains practically normal, vomiting is rare, and the general condition is often but slightly upset. The power of reaction in the aged is comparatively small, and by the time a correct diagnosis has become feasible gangrene and perforation have often occurred. In all the author's cases the local symptoms were marked, the pain in some being like that of the most severe colic.

632. Masked Cystalgic Pyelitis.

PRONZINI (Archiv. Ital. di Chirurg., December 20th, 1920) draws attention to a form of pyelitis characterized by painful and frequent micturition both day and night, and often very uniform in its regularity. The pain lasts a long time. The patients are often neurasthenic, or become so from the long suffering. The urine is more or less turbid, but contains no tubercle bacilli, and haematuria is present only occasionally at the end of micturition. Pain in the renal region is not a marked feature, and as a rule the general condition is good. The pain, chiefly over the bladder or in the vagina, makes one think of cystitis, but there is no cystitis. Catheterization of the ureters shows there is pyelitis. There may be some tenderness over the classical renal or ureteric painful spots, but this is not a constant sign. The urine is turbid, often acid, contains a little albumin, and pus cells. There is no bacilluria. There is a certain amount of functional limitation and a diminution of the power of concentration in the urine (hyposthenuria). The cystoscope shows no sufficient cause for the symptoms in the bladder, and the ureteral orifices are, as a rule, normal. In treatment it is very important never to over-distend the bladder; instillation is therefore better than lavage.

633. Iodine Powder as a Substitute for Tincture of Iodine.

SCHERINGA (Nederl. Tijdschr. v. Geneesk., March 19th, 1921) remarks that, though tincture of iodine is a rapid and effective antiseptic, it possesses certain drawbacks. In the first place it requires to be freshly made, as if kept any length of time various irritating compounds are formed. Another disadvantage of tincture of iodine is that it rapidly acts on cork, so that the bottle containing it does not close tightly and the alcohol soon evaporates. On the other hand, a dry powder composed of iodine and talc—21 to 5 per cent.—has none of these drawbacks, and is much cheaper, pleasanter to use, and easier to apply.

OBSTETRICS AND GYNAECOLOGY.**634. Perineal Hysterectomy.**

CUNEO and PICOT (Journ. de Chirurgie, March, 1921) describe the technique of an operation for total hysterectomy by the perineal route in cases of cancer of the cervix. Their operation differs from paravaginal hysterectomy by use of Schuchardt's incision and approach combined with Schauta's closure of the vagina after dissection of a cylindrical cuff; it resembles Zuckerlandl's hysterectomy after perineotomy in that the cutaneous incision has its convexity directed forwards and is made in a transverse direction from one to the other tuber ischii. The steps of the operation are: (1) Opening of both ischio-rectal fossae and separation of the rectum from the vagina as far as the pouch of Douglas; (2) median incision of the posterior vaginal wall and transection of the vagina at the upper limit of this incision; (3) dissection of the vaginal wall above the transection, an iodine tampon being placed over the cervix; (4) separation of the cervix from the bladder and opening of the vesico-uterine cul-de-sac; (5) ligation of the vaginal and uterine arteries; (6) division of the round ligaments, followed by removal of the uterus, adnexa, and vaginal cuff; (7) reunion of the peritoneum and suture of the lower portion of the vaginal wall together with the perineal incision. According to Cunéo and Picot, this operation is particularly useful in the case of obese subjects, abdominal operation on whom in the high pelvic position presents difficulties both to the surgeon and to the anaesthetist. The lithotomy position is adopted and the authors prefer spinal anaesthesia.

635. Caesarean Section for Obstruction by Ovarian Cyst.

RIVIÈRE (Journ. de Méd. de Bordeaux, March 10th, 1921) reports a case of a primipara, aged 23, on whom a Caesarean section was performed. He examined the patient when she was seven months pregnant, and found that the head would not engage. On vaginal examination the cervix was felt pushed forward, and there was a hard tumour in the posterior fornix. At first this was mistaken for a foetal hand, but on a further examination two weeks later it was diagnosed as an ovarian cyst. A successful Caesarean section was thereupon performed.

636. Cancer of the Cervix of Borderline Operability.

WEISS (Amer. Journ. of Obstet. and Gyn., April, 1921) records his conclusions regarding the treatment of borderline cases of carcinoma of the cervix, defined as "cancer with a moderate amount of tissue friability and fixation of adjacent structures, which fixation may be malignant or inflammatory in character," and including also early cases of adeno-carcinoma, of which the prognosis is much worse than of the squamous-celled cauliflower type of growth. A few days' rest in bed is always advisable as a preliminary to operation; in addition to an improvement in the general condition, it happens not infrequently that a diminution becomes manifest in the thickening and fixation of the broad ligaments, proving that these signs were due to inflammatory rather than to malignant invasion of the lymphatics, so that a supposedly inoperable case becomes operable or "borderline." When a doubtful borderline condition is present, treatment by radium is advisable (1) as the sole therapeutic measure when operation is contraindicated by reason of age, general condition, or renal or cardio-vascular affection; (2) in other cases as the initial measure, the performance of subsequent operation being determined by the reaction obtained. Such treatment appears to give somewhat better results than the improved Byrne cautery technique. In fifteen borderline cases the author has had good results, free from fistula formation, by high cautery amputation of the cervix, followed by application of radium (1,200 to 2,000 mg.-hours); high amputation by the cautery is preferable to the so-called Percy cauterization. For the prevention of untoward complications following radium therapy, Schmitz's precaution of keeping the bladder and rectum empty during the application is important. The author speaks with reserve of radium treatment as a preliminary to radical operation; a dosage of 2,400 mg.-hours of radium element does not as a rule, it is said, produce heavy scar tissue.

637. High Forceps Operation in Contracted Pelvis.

MEUMANN (Zentralbl. f. Gynäk., April 30th, 1921) reports, among 2,432 cases of contracted pelvis, 103 labours in which delivery was essayed or accomplished by high forceps operation. This procedure is adopted (symphysiotomy or Caesarean section being contraindicated)

when (1) the foetus is alive and urgent maternal conditions make speedy delivery imperative; (2) the mother's condition is satisfactory but the foetal life is in danger, which may be averted by forceps delivery. If several forcible tractions prove unsuccessful perforation is performed, the foetus usually being moribund. Extraction was successful in 84 cases, and the child was born alive in 60. Analysis of the figures appears to show a smaller foetal mortality by application of forceps to the head after its engagement. As regards foetal survival, the prognosis in the generally contracted cases is seen to be worse than in the flat pelvis. The series was free from maternal mortality.

688. The Cuti-reaction during Menstruation and after Ovariectomy.

COULAND (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 17th, 1921) performed the cuti-reaction in 80 cases during and apart from the menstrual period, and in 5 found that it was negative at the onset of menstruation, and also negative in 2 cases when menstruation was expected to appear but was delayed. In 12 cases there was a distinct difference in the reactions performed during and apart from menstruation, the menstrual cuti-reaction being much less pronounced. In no case was a cuti-reaction which was negative between the monthly periods positive during menstruation. Couland also performed the cuti-reaction in 53 patients who had undergone ovariectomy on one or both sides, and on 53 controls who had had various other operations, the results being as follows: After unilateral ovariectomy the number of negative cuti-reactions was 44 per cent., and after bilateral ovariectomy 50 per cent., whereas after various other operations it was only 19 per cent. The onset of menstruation and ovariectomy therefore appear to the author to be accompanied by a phase of tuberculin anergy similar to that observed during labour by Nobécourt and Paraf.

689. Pelvic Lavage in Treatment of Pyelitis of Pregnancy.

In a preliminary report by BANGMAN (*Amer. Journ. of Obstet. and Gynec.*, February, 1921), the author gives details of six cases of pregnancy pyelitis treated by washing out the pelvis of the kidney. All the cases were improved to some extent, but it was still considered advisable to induce labour as soon as the child was viable. The article is illustrated by interesting reproductions of bromide pyelograms.

690. Semi-symphysiotomy.

COSTA (*Zentralbl. f. Gynäk.*, February 12th, 1921), describes a very original operation for cases of flat pelvis obstructing labour. Put briefly, the operation consists in shaving a piece off the posterior surface of the symphysis pubis. The author maintains that: (1) It is practically a bloodless operation; (2) that it is an easy operation, without any risks; (3) that it increases the true conjugate by 2½ to 3 cm. He gives details of four cases in which he has successfully performed this operation.

PATHOLOGY.

691. The Blood in Osteomyelitis.

PEWNY (*Wien. klin. Woch.*, March 10th, 1921) examined the blood in eighteen cases of osteomyelitis before and after operation, with the following results. Before the operation the total number of leucocytes was often considerably increased (up to 17,000), normal values being very rarely found. The neutrophil leucocytes were also increased up to 89 per cent. or 14,000. The number of lymphocytes was much diminished in a large number of cases, and increased in a small number of cases, but in the latter the presence of tuberculosis was probable. The condition of the eosinophils varied considerably, a diminution being often observed. Another examination made two or three weeks after sequestrectomy showed a considerable diminution of the leucocyte count, the number of the neutrophils being normal, and often below the normal. The number of lymphocytes had usually returned to the normal, and there was an increase in the eosinophils, indicating that the infection was cured. The number of the red cells and the haemoglobin, still showed a reduction in the third week after the operation. The leucocyte count did not always correspond to the size of the sequestrum or to the degree of suppuration.

692. Transmissibility of Human Herpetic Keratitis to the Rabbit's Cornea.

LUGER and LAUDA (*Wien. klin. Woch.*, March 24th, 1921) state that Gruter's discovery that herpetic keratitis in man can be transmitted to the rabbit's cornea has recently been confirmed by a number of writers, such as Dörr and Vochting, Kraupa, Löwenstein, Stoker, Sulmann, and the present writers. Although hitherto characteristic changes had not been described in the rabbit's cornea inoculated with human herpetic keratitis, Luger and Lauda were able to demonstrate in the epithelial cells of the inoculated cornea certain changes in the nuclei resembling those found by themselves and independently by Lipschütz in febrile herpes, a result which was to be expected owing to the clinical relationship of corneal and febrile herpes to one another. The changes in the nuclei consisted in a displacement of the chromatin to the periphery of the nucleus and a thickening and crumpling of the nuclear membrane, while the inner part of the nucleus was filled with a homogeneous mass which showed a distinct predilection for acid dyes.

693. Epithelioma following X-Ray Treatment for Tuberculosis of the Knee.

KJÆRGAARD (*Hospitalstidende*, March 30th and April 6th, 1921) reviews the literature of x-ray malignant disease, and contributes the case of a woman, aged 22, who from the age of 12 and for the next five years was given x-ray treatment at irregular intervals for tuberculosis of the knee. Following an injury to this knee, chronic ulceration supervened, and ultimately a typical epithelioma developed. The patient refused amputation till it was too late, and the necropsy showed extensive tuberculosis of the lungs and intestines, as well as amyloid disease. There was no secondary malignant disease, not even in the regional lymphatic glands. Discussing x-ray malignant disease, the author classifies it according as it develops in persons working with the x-rays, or in patients treated by them. By 1911, 54 cases belonging to the second category had been recorded, and these did not include cases occurring in the subjects of lupus, for this disease is apt to be followed by malignant disease even in the absence of x-ray treatment. Since 1911 only a few cases of x-ray malignant disease have been reported as a sequel to therapeutic exposures, but the author thinks this present immunity may be more apparent than real, and that the relation of cause to effect may often be obscured by the length of the interval (several years) between x-ray treatment and a manifestation of malignant disease.

694. Application of Cutaneous Sensitization to Diseases of the Skin.

ENGMAN and WANDER (*Arch. of Derm. and Syph.*, March, 1921), following on the work of Chandler Walker in relation to asthma, tested the sensibility of the skin to various proteins, such as wheat, milk, egg, beef, pork, potato, bean, also proteins of *Staphylococcus albus*, *aureus*, and *citreus*. The tests were made through an incision 1/8 in. long on the inner side of the forearm by a very sharp scarifier, producing as little trauma as possible. The part was then moistened with saline, and the protein about to be tested added. Half an hour was always allowed for the reaction, but often a positive reaction developed in a few minutes. The diseases studied in this way were acne, urticaria, erythema multiforme, pemphigus, trade dermatitis, dermatitis vegetans, and the eczema group. From the excellent results obtained cutaneous sensitization tests are, the authors state, especially valuable in urticaria and eczema. To be of most value it is essential to study a case with those proteins with which the patient comes in contact in his daily life. From a therapeutic standpoint the difficulty is the control of the diet, but where control can be exercised excellent results follow. Desensitization of a case is sometimes possible.

695. B. tetani in the Digestive Tract of Herbivora.

ACCORDING to NINNI (*Ann. d'igiene*, December, 1920), *B. tetani* can always be found in various segments of the gastro-enteric canal of small laboratory herbivora, such as rabbits and guinea-pigs, by means of broth cultures. The bacillus is almost always toxic, but its toxicity varies. To determine the toxicity the only certain method is to use a pure culture by heating the faeces to 60° C. for an hour to eliminate the non-sporing organisms, especially those which interfere with the production of toxin, such as *B. bulgaricus*, *B. acidi lactici*, and *B. mucosus capsulatus*.

Remarks

RADIUM THERAPY IN UTERINE CANCER.

A. E. HAYWARD PINCH, F.R.C.S.

MEDICAL SUPERINTENDENT, THE RADIIUM INSTITUTE

Of all diseases to which the female sex is subject carcinoma of the uterus is probably that most productive of constant discomfort, incessant pain, and ever-present mental anguish. To a woman the dreaded diagnosis "cancer of the womb" often appears as the equivalent of a death sentence.

The expectation of life of untreated cases rarely exceeds two years, and in the majority of instances fifteen or eighteen months sees a fatal termination.

Until the introduction of Wertheim's abdominal hysterectomy, surgical measures, if adopted, consisted either of local excision of the diseased cervix, or the performance of vaginal hysterectomy, operations which, in the majority of instances, were followed by speedy recurrence. Wertheim's hysterectomy in skilful hands offers, however, a much better prospect of complete recovery from the disease, but the mortality attendant thereon cannot be lightly regarded, and in many cases when the preliminary laparotomy has been performed an inspection of the pelvic cavity shows that the disease is already too widely disseminated to permit of complete eradication. Other methods tried from time to time, consisting chiefly of the local application of caustic pastes of one kind or another, have little more than a transient palliative effect, the disease returning with renewed vigour so soon as the local reaction has subsided.

Radium has been widely used for the treatment of carcinoma of the uterus, but the results, obtained by different workers have varied very greatly. Some claim that radium treatment should be used in all cases in preference to operative measures, whilst others content themselves with saying that whilst it produces very great and definite symptomatic improvement, it never effects a cure of the disease. The truth probably lies somewhere between these two views.

CARCINOMA OF THE CERVIX.

Classification of Cases.

It would serve no useful purpose in a paper of this character to discuss the vexed question as to the microscopic pathology of carcinoma of the cervix uteri, and from the point of view of radium treatment it appears to matter little whether the growth originates in the columnar cells of the mucous membrane of the upper two-thirds of the cervical canal or from the squamous epithelium of the mucosa covering the cervix and the lower third of the cervical canal. In many instances microscopic sections show so much metaplasia of the malignant cells that it is impossible to say from which class of epithelium the growth originated. From the macroscopical appearances, however, it is justifiable to divide these growths clinically into three classes:

1. *The Endocervical or Medullary Type.*—These tumours originate in the mucosa of the cervical canal and form circumscribed nodular growths, unaccompanied by any external ulceration; the predominant early symptoms are an occasional slight uterine haemorrhage and a scanty vaginal discharge. Vaginal examination reveals little more than an enlarged and somewhat nodular indurated cervix. These growths sooner or later break down, ulceration and disintegration rapidly occur, and the cervix is speedily transformed into a crateriform ulcer, with its apex at the internal os; its walls are thin, hard, and extremely friable. This is by far the most malignant type of the disease; lymphatic infection takes place at an early date, and involvement of the base of the bladder, leading to the formation of a vesico-vaginal fistula, is commonly observed.

2. *The Flattened Ulcerated Type.*—This condition in its early stages is often mistaken for a simple erosion, although it is probable that not infrequently a chronic erosion forms a starting point of the malignant process. These growths occur as flattened superficial ulcers, with hard edges, and granular vascular base. They tend to spread widely over the surface of the cervix, and to invade the anterior and posterior fornices. The rate of growth is relatively slow,

and infection of the lymphatics and parametrical tissues is not so rapid or extensive as in the case of Group 1.

3. *The Proliferative Fungating Type.*—This class is characterized by the so called "cauliflower" growth, which springs from the extremity of the cervix, forming an irregular, fungating, friable mass which sometimes almost fills the vaginal cavity. This class of growth shows comparatively little tendency to invade the substance of the cervix proper, and is perhaps the least malignant of the three types.

Mode of Spread.

The method of spread of the disease has been clearly established, and follows very definite lines. Direct extension occurs by permeation of the lymphatics covering the uterus, of those running through the utero sacral ligaments, and also, though to a lesser degree, of the lymphatics of the broad ligaments. With this permeation some degree of cellulitis is often associated, so that the peri-uterine induration is generally of a composite character, inflammatory and carcinomatous.

Glandular infection takes place but slowly. As a general rule the iliac groups are the first to be affected, followed later by the sacral glands; as the disease progresses, the lateral lumbar and superficial inguinal glands are attacked. With the associated inflammatory infiltration fixation of the uterus occurs, and there is persistent pain, referred to the lower part of the pelvic cavity; it often radiates into the thighs, and this may be regarded as due to infection of the deeper glands; it is to be looked upon as a strong contraindication to operation.

The symptom which usually first attracts the patient's attention is intermittent uterine haemorrhage, and since the age incidence of the disease corresponds very nearly with that of the menopause, many patients regard the intermittent haemorrhages as being associated with the establishment of the climacteric, and for that reason do not seek advice until the symptoms of a persistent, copious, offensive vaginal discharge and severe pelvic pain are superadded, thus it happens that too frequently, when a patient submits to examination for the first time, the disease is found to have progressed beyond the reach of surgical measures.

Selection of Cases.

When considering the question of radium therapy, cases should be classified into three groups as follows:

1. *Operable Cases.*—The procedure invariably adopted at the London Radium Institute when a case of early operable carcinoma of the uterus presents itself for examination is strongly to urge immediate operation, followed, when the patient has recovered, by a course of prophylactic irradiation. It is not justifiable to advocate radium treatment in lieu of surgical measures, and for that reason no patient is taken for treatment unless she has positively declined to submit to operation.

2. *Border-line Cases.*—This term is used in reference to that class of case in which the extent of the disease and the amount of infiltration and degree of fixity of the uterus are of such a character that the surgeon is unable to declare positively that the condition is operable; and here it is that radium is often of the greatest use, as by its means much of the existing ulceration is healed, the inflammatory infiltration reduced, and the haemorrhage arrested, so that the removal of the uterus can be more satisfactorily accomplished.

3. *Inoperable Cases.*—In these conditions radium will frequently, almost invariably, produce a degree of symptomatic improvement which is unobtainable by any other methods. Haemorrhage is arrested, discharge diminished, ulceration healed, pain ameliorated, and the progress of the disease checked, sometimes almost completely arrested, the patient's general health being improved in every way.

METHODS OF TREATMENT.

Each case must be judged on its merits, and the procedure varied according to the condition present.

1. Endocervical Type.

When dealing with cases of the endocervical type, before much breaking down of the substance of the cervix is apparent, vigorous treatment should be adopted. A tube of 100 to 150 mg. activity, screened with 1 mm. of silver, should be introduced into the cervical canal for twenty-four hours, and this may advantageously be supplemented

by the insertion of tiny emanation tubes of about 25 or 30 mg. activity, screened with 0.3 mm. of platinum, into the nodular infiltration of the cervical walls. Three or four such tubes may be used, according to the amount of infiltration present, and should be allowed to remain in position for periods of twelve hours. A definite reaction ensues, and in favourable cases the resultant fibrosis causes shrinking and hardening of the cervical tissue, compressing the invading acini, and inducing disintegration of the contained cells.

It is advisable, at the same time, to supplement this local treatment by radiation of the whole body of the uterus, and the pelvic cavity generally, and for this purpose powerful applicators, screened with 2 mm. of lead, should be applied externally immediately above the pubes and in both iliac fossae, an exposure of twenty-four hours' duration being given. This radiation serves to arrest or retard the lymphatic permeation and general spread of the disease by direct extension from the cervix to the immediately surrounding parts.

2. Flattened Ulcerated Type.

Where the disease is of a superficial ulcerative character better results are obtained by placing the radium applicators in direct contact with the diseased portions of the cervix; it is in these cases that the use of emanation applicators is to be commended, as it is possible with them to concentrate the activity to a very great degree, and to make the applicator of a size and shape exactly fitted to the area treated.

The tubes may be kept in contact by careful packing with gauze, or still better by the use of dental modelling compound. A mould of the diseased cervix is made, and withdrawn, screened emanation tubes are then embedded in it at those parts which will come into contact with the diseased surfaces, and the mould reinserted. The exposure to be given varies with the strength of the tube and the screening employed, though, as a general rule, with screening of 2 mm. of lead, or its equivalent in some other heavy metal, an exposure of twenty-four hours' duration should suffice.

The same procedure with regard to radiation of the pelvic cavity as indicated in the preceding type should be adopted.

3. The Proliferative Fungating Type.

Here it is advisable, before undertaking treatment, to remove as much of the growth as possible by excision or curetting, and then to treat the remains of the cervical stump. This should be accomplished by the insertion of a 100 mg. tube, screened with 1 mm. of silver, into the cervical canal for twenty-four hours, and the use of tiny platinum screened emanation tubes inserted into any remaining outgrowths that may be present. Here, too, the general radiation of the body of the uterus and pelvic cavity should invariably be adopted.

All patients should afterwards be examined at frequent intervals, and the exposures repeated as and when necessary, though it is advisable not to repeat the treatment at intervals of less than five or six weeks. The vaginal mucosa appears to be much more susceptible than the uterine to radium irradiation, and for this reason it is advisable as far as possible to protect the non-infected vaginal mucous membrane by packing, or the interposition of lead and rubber sheeting. Special attention should be paid to the recto-vaginal septum, as unless this protection be given definite proctitis is sometimes produced in very susceptible subjects. The inflammatory reaction resulting from the treatment described is rarely great, but some degree of vaginitis usually appears about a week or ten days after the exposure, and on this account patients should receive a vaginal douche regularly night and morning for four or five weeks after each exposure, in order to prevent the possible occurrence of adhesive vaginitis.

The amount of symptomatic benefit which the majority of patients experience after the treatment is very striking. Haemorrhage is usually arrested more or less completely within a fortnight of the exposure, the discharge is also greatly diminished, the surrounding infiltration lessened, and the pressure symptoms, such as obstructive constipation, and difficulty or frequency of micturition, much ameliorated. In many cases the pain too is greatly relieved, though when due to pressure of enlarged glands on

nerves of the sacral plexus it is not nearly so frequently benefited.

Ultimate Prognosis.

Many instances are on record amongst the case sheets of the Radium Institute in which patients who have come for treatment at a time when the disease was manifestly inoperable and very extensive, have lived for three, four, or five years from the date of their first treatment, and for the greater part of that period have been free, or almost free, from the more distressing symptoms of their complaint. In some cases the improvement, both local and general, has been so great as to induce the hope that the disease had been completely arrested and the patient apparently cured, but unfortunately sooner or later symptoms have appeared indicative of the infection of parts beyond the effective range of radium, and the disease has slowly progressed to a fatal termination.

Recurrence after Hysterectomy.

Patients suffering from recurrence after hysterectomy often do exceedingly well, more especially if treated within a short time of the appearance of the recurrence. The technique adopted is governed almost entirely by its position and shape. If nodular, and situate at the vaginal vault or on the recto-vaginal septum, the actual insertion of an emanation tube, screened with 1 mm. of silver, for twenty-four hours will often bring about a cure. If recurrence is not very frequent, and is situate on the anterior vaginal wall the proximity of the urethra renders the insertion of a tube into the mass a somewhat hazardous procedure, as it might be followed by the production of a fistula, and for this reason the treatment has to be carried out by means of a leaden screened applicator applied in contact with the vaginal surface of the nodule, supplemented by a smaller silver-screened tube applied within the urethra for two or three hours on four or five successive days. In this way fibrosis of the nodule with encapsulation of the enclosed cells is often obtained, and the risk of a vesico-vaginal fistula obviated.

CARCINOMA OF THE BODY OF THE UTERUS.

This condition is much rarer than carcinoma of the cervix, and comparatively few cases have occurred in the practice of the Radium Institute; the total number has not exceeded 2 per cent. of all the cases of uterine cancer treated. In etiology it differs from that of carcinoma of the cervix in two chief particulars—it is more prone to occur after the establishment of the menopause, and is most generally met with in nulliparae.

Carcinoma of the body of the uterus originates in the cells lining the uterine glands, which proliferate, invade, and destroy the submucous and muscular tissues, and at a late stage of the disease may even perforate the peritoneal covering and infect the abdominal cavity. The onset is very insidious, and diagnosis frequently presents considerable difficulty; but the occurrence of slight persistent uterine haemorrhages, with a more or less uniform enlargement of the body of the uterus in an elderly woman, is always strongly suggestive of malignant disease of the body. The exact diagnosis can, however, often only be established by dilating the cervical canal and removing a portion of the uterine mucosa with a curette for microscopical examination.

Hysterectomy for cancer of the body of the uterus gives more encouraging results than in cancer of the cervix. Dissemination does not take place so rapidly, and is rarely very extensive; fixation of the uterus is a very late feature, and its removal is usually easy; for these reasons the prompt performance of a complete hysterectomy should be urged upon all patients directly the presence of the disease has been clearly established. If, however, the patient positively refuses operation, or has not sought advice until a time when the condition is so far advanced as to be inoperable, then radium treatment should be resorted to.

The routine treatment consists of the introduction of a tube of 150 or 200 mg., screened with 1 mm. of silver, into the uterine cavity, the cervical canal having been, previously dilated to a degree sufficient to permit of the passage of a tube with ease. The invasion of the uterine walls by the carcinomatous cells renders them extremely friable, and unless great care is taken in introducing the tube, perforation of the wall may quite easily be produced.

The tube should be maintained in position by light gauze packing, and an exposure of twenty-four hours' duration given, the treatment being repeated after an interval of at least two months.

It is advisable in these cases also to give a general external irradiation to the whole pelvic cavity, with powerful applicators screened with 2 mm. of lead applied above the fundus of the uterus and in both iliac fossae.

Recurrences after hysterectomy for carcinoma of the body of the uterus are extremely susceptible to radium therapy, and their disappearance under appropriate dosage may be confidently anticipated.

Prophylactic Irradiation.

Though all workers are in agreement in saying that this procedure is often of great value, great diversity of opinion prevails as to the best method to be adopted.

There are three periods at which prophylactic irradiation may be administered—namely: (1) five or six weeks before the operation; (2) two or three days before the operation; (3) three or four months after the operation.

(1) *Radiation some five or six weeks before the operation* is of particular use in "border line" cases with much peri uterine infiltration of a doubtful character. If properly carried out radiation will often reduce the amount of infiltration very considerably, circumscribing its limits, so rendering them more definitely appreciable, and thus enabling the actual extent of the infection to be more easily estimated. On the other hand, the reduction of the inflammatory infiltration is associated with a certain degree of fibrosis, and this, whilst limiting the spread of the disease, at the same time renders the removal of the uterus a little more difficult, and so lengthens the operation. It is unwise to allow a period exceeding six weeks to elapse between the preliminary irradiation and the operation, for if this time limit be passed the fibrosis becomes very pronounced, and of an almost scirrhotic character.

(2) *Prophylactic Irradiation immediately before the operation.*—This is of great service in cases of the fungating type. As a preliminary to the main operation as much of the cauliflower growth as possible should be removed by curetting or excision, and a tube of not less than 150 mg. activity, screened with 1 mm. of silver, introduced into the cervical canal two or three days before the operation. An exposure of twenty four hours' duration should be given. The irradiation obtained in this fashion will suffice to exert a lethal effect on any disseminated cells in the immediately surrounding tissues or lymphatics, but there will not be time for the development of fibrotic changes, which would serve to impede the performance of the major operation. As most of the irradiated tissue will be removed by the surgical procedure, only small isolated foci of the disease will remain, and these the radiation will probably have affected so powerfully as to produce their ultimate degeneration.

(3) *Irradiation Three or Four Months after the Operation.*—This should be done as a routine procedure after all cases of Wertheim's hysterectomy for malignant disease, but considerable caution must be observed in its performance. The elaborate and extensive dissection which is associated with Wertheim's operation appears seriously to impair the functions of the trophic nerves of the pelvis, and it is some time before they return to the normal. Too heavy a dose given at too early a date may result in an excessive reaction, with the production of vesico vaginal or recto vaginal fistulae. For these reasons, therefore, it is advisable to limit the intravaginal treatment very considerably, not to treat the case until at least three months have elapsed, and then to use a tube of not more than 50 to 70 mg. activity, screened with 2 mm. of lead and rubber, an exposure not exceeding twenty-four hours' duration being given, preferably in two or three periods of twelve or eight hours each. In this way any intense local reaction is avoided, and the possibilities of fistulous formation abolished. A powerful external irradiation may, however, be given with safety, applicators containing 200 or 300 mg., screened with 2 mm. of lead, being applied externally above the pubes and in both iliac fossae, so as thoroughly to irradiate the whole area. The total exposure in this situation may be of from twenty to thirty hours' duration.

Reaction.

The reaction following on treatment carried out in the manner above indicated is not, as a rule, great or severe. There is a considerable difference in the resisting power of the vaginal and of the uterine tissues; the former are much more susceptible; for this reason it is inadvisable to use silver screening if the apparatus is likely to be in contact with the vaginal mucosa for a period of twenty-four hours, as it is possible that, if the tissues have been infiltrated by carcinomatous cells, considerable destruction, perhaps leading to perforation, may occur; lead screening of at least 2 mm. thickness, with a rubber sheath of 3 mm., should therefore be used whenever the exposure is mainly vaginal in character.

If, on the other hand, the tube is to be completely embedded in the cervical canal, this contingency does not arise, and a screening of 1 mm. of silver only may be employed with impunity.

Stiffness.

As a general rule patients suffer little pain or discomfort after the exposure. In most subjects some slight degree of congestive vaginitis appears in about a week or ten days, and for this reason patients are advised to douche freely night and morning for four or five weeks after the treatment is finished. If this precaution be not observed some degree of adhesive vaginitis may ensue, and the resulting adhesions may have to be forcibly broken down at a later date, causing the patient considerable pain and annoyance.

In extremely susceptible subjects a slight transient proctitis has been noted, but this is very infrequent, and when it does occur it is always of a mild degree, and speedily yields to routine treatment.

In patients who have received repeated exposures at intervals of two or three months for periods of one, two, three, or more years much fibrosis is induced in the vaginal wall, and the associated contraction narrows the canal very greatly, its diameter being reduced to that of a lead pencil, or even less.

In inoperable cases occurring in women who have not passed the menopause external irradiation applied with the object of retarding the general extension of the disease usually suppresses the ovarian functions, leading to amenorrhoea or the premature induction of the climacteric.

In untreated inoperable cases the formation of vesico-vaginal or recto-vaginal fistulae is an almost invariable phenomenon in the later stages of the disease; radium treatment properly administered serves rather to retard the appearance of these fistulae than to hasten their development. An excessive prophylactic dose administered too soon after the performance of Wertheim's hysterectomy may, however, induce a reaction of such degree that much breaking down of the recto vaginal and vesico-vaginal walls may be induced, and fistulae established; it is for this reason that the precautions previously alluded to when speaking of post-operative prophylactic irradiation should be strictly observed.

General Treatment.

Douching after radium treatment should be carried out as a matter of routine, and is best performed by means of the ordinary douche can with a soft rubber nozzle; the use of a ball enema syringe should be strictly interdicted. Glycothymoline—one part in twenty of warm water—is soothing and cleansing; lysol, tincture of iodine, and sanitas are also of great value when there is much offensive vaginal discharge; in some cases a weak boracic lotion or solution of potassium permanganate will suffice.

In cases of long standing, where there is pronounced infection of the parametric tissues and the pelvic glands, pain is generally a constant and distressing feature, and it is often difficult to find a means of combating this symptom. Aspirin, phenacetin, pyramidon, and other analgesic synthetic compounds should be freely tried before resorting to the use of opiates, but in many cases a cachet containing 4 grains each of aspirin, phenacetin, and pulv. ipecac. co., administered in a glass of hot milk at bedtime, gives great and immediate relief, and ensures the patient a comfortable night's rest.

As an adjunct to radium treatment, injections of colloidal selenium often prove of considerable use, as they serve to diminish the pain and tenderness, cleanse the ulcerated

surfaces, and cause a decrease in the amount of discharge. The procedure usually adopted is to give a dose of 5 c.cm. intramuscularly every fourth day until six such injections have been given. A further series of six at seven-day intervals is then administered, and a period of one week permitted to elapse, during which the patient receives the radium treatment. The majority of patients tolerate these injections very well, but in a small percentage of cases a definite systemic reaction is observed, patients complaining of pain at the site of injection, with sickness, headache, and a slight rise of temperature; if these symptoms are at all pronounced they must be regarded as a contraindication to the continuance of the treatment.

THE TREATMENT OF ACUTE PYOGENIC INFECTION OF THE KNEE-JOINT.

BY

A. H. SOUTHAM, M.A., M.Ch.Oxon., F.R.C.S.Eng.,
RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

Acute pyogenic infection of the knee-joint may arise as the result of a wound of the joint, by extension of inflammation from a neighbouring focus, or in conditions such as septicaemia and pyaemia where the organisms gain access to the joint from the blood stream.

The treatment recommended in the older textbooks was by making vertical incisions on either side of the patella and inserting drainage tubes into the joint. This was often followed by disastrous results, the infection tracked along the fascial planes up into the thigh and down the calf, where, later, secondary abscesses had to be incised, whilst the patient's general condition steadily deteriorated and amputation had finally to be performed as a life-saving measure.

It is not going too far to say that the presence of a drainage tube in the knee-joint almost inevitably ends in disaster. It acts as an open drain for the entrance of secondary organisms from without, and as a foreign body in the joint which serves to keep the inflammatory process active. Further, from a study of the anatomy of the knee-joint, it will be apparent that attempts to drain the joint must be inefficient.

The synovial membrane lining the knee-joint has, like the peritoneum, considerable power for overcoming septic infection when placed under suitable conditions. But it must be remembered that the virulence of organisms is much greater when they are contained, under pressure, in a closed cavity such as the acutely inflamed and swollen knee-joint. For the successful treatment of acute arthritis, therefore, it is necessary to place the synovial membrane under the most favourable conditions, and to lower the intra-articular tension and keep it so reduced without the use of drainage tubes. In mild types of infection this can sometimes be accomplished by aspiration or by incision and lavage, followed by suture of the joint, but in acute pyogenic infection this often fails, the joint fills up again and again, and it becomes obvious from the patient's general condition that something radical must be done.

During the war the treatment of acute suppurative arthritis of the knee furnished one of the most difficult problems of surgery. In the early days it was said¹ that surgeons were in potent to prevent the loss of life or limb in these cases. Later, with improved methods and greater knowledge, better results were obtained, though, in many cases, it was impossible to overcome the infection, and amputation had to be resorted to.

Willems, the Belgian surgeon, suggested treatment² of these cases by active movements on the part of the patient to provide free drainage after incision of the joint. But it is difficult to persuade patients to move an acutely inflamed joint, and I have had little success with this procedure. It is, I think, open to question whether it is advisable to start immediate movement of a joint infected by streptococci in a patient who is already in an acutely toxic condition. As a result of experience gained in the war I have adopted the treatment here described in cases of acute pyogenic infection of the knee-joint, arising from general causes, with satisfactory results. The patients have been left with a useful limb and a movable joint. The number of cases is so limited that I would not presume to draw definite conclusions, yet the method seems worthy of

further trial; it is simple, and the after-treatment and dressings are reduced to a minimum; it has, in my hands, given more satisfactory results than can be obtained by other methods of treatment.

In 7 cases it was successful, the patients having left hospital with movement in the joint which was steadily improving. The last case, one of acute osteomyelitis of the tibia and pyaemic infection of the knee-joint, proved fatal from generalized pyaemic abscesses and pericarditis. *Post-mortem* examination of the knee-joint, two weeks after the operation, showed the joint structures to be healthy, and no pus was present in the joint, the acute condition having completely subsided.

Method of Procedure.

Operation should be immediately carried out when pathological examination of the fluid withdrawn from the joint shows that pus cells and pyogenic organisms are present.

Under general anaesthesia the knee-joint is opened by two lateral incisions, on either side of the patella. These extend from the head of the tibia to the upper limit of the subcrural pouch. A tourniquet may be used, or the bleeding points, which are numerous, may be caught in artery forceps; these forceps can be removed later, no ligatures being necessary.

The joint is then thoroughly irrigated with hot saline solution, by means of a Higginson's syringe. Every corner of the joint is explored with the nozzle of the syringe and the knee is flexed and extended to ensure thorough lavage. The irrigation should be continued for ten minutes. The synovial cavity is then dried with lint swabs soaked in ether and held in artery forceps. When this has been completed a small quantity of bipp is applied systematically to the articular surfaces and synovial membrane lining the joint. No sutures are used, the lateral incisions being left open for drainage.

About a dozen turns of broad gauze are then wrapped round the joint, plenty of wool and a firm bandage being applied over this. A strapping extension is fixed to the leg and the limb placed in a Thomas splint, with the knee slightly flexed. The patient is then returned to bed and a light weight applied to the extension.

The temperature usually falls about the third day and the patient's general condition rapidly improves. The dressing is not changed till the fourteenth day, when a fresh one is applied, a little bipp being at the same time rubbed over the lateral incisions. The acute symptoms have usually completely subsided by this time; the splint is now removed and the patient encouraged to move the joint. Massage accompanied by active and passive movements is carried out, and the patient should start walking, when the conditions permit, as early as possible. The dressing is changed about every seven days or as required.

The lateral incisions remain healthy and clean throughout, though it is usually several weeks before they are healed. Probably if secondary suture was adopted this stage might be considerably shortened.

CASE I.

C. D., a miner aged 21 years, was admitted to the Manchester Royal Infirmary on November 3rd, 1920. He stated that whilst working in the mine on October 27th he knocked his right knee against a sharp stone; the knee swelled up and he had been treating it at home. He was found to have a dirty ragged wound on the inner side of the knee, which opened into the joint, from which pus could be expressed. Bacteriological examination showed that streptococci were present. The temperature was 103° F. and the pulse 153.

The knee was treated on the lines described. The temperature fell to normal on the fourth day. When the wounds were dressed on the fourteenth day a small abscess was found in the calf; this was incised. The temperature remained normal throughout, and he was discharged from hospital on January 15th, 1921. The knee could then be flexed to a right angle, the joint was normal in size, and the wounds nearly healed. I have seen the man constantly since; he walks well and has a good range of movement in the knee-joint.

CASE II.

P. A., a butcher, aged 32 years, was admitted to the Royal Infirmary on September 27th, 1920, with a compound comminuted fracture of the right tibia and fibula, the result of a street accident. The wounds became badly infected, and a street accident. The wounds became badly infected, and several operations were performed on the leg. His progress was satisfactory till January 8th, when he suddenly had a rigor and the temperature reached 104° F. The rigors continued,

and his knee was then found to be swollen and acutely tender. Pathological examination of the joint fluid showed that pus cells and streptococci were present. The patient was continually asking for the leg to be amputated.

On January 12th it was decided to give the treatment above described a trial. This was carried out, and his condition rapidly improved, the temperature becoming normal on January 16th, and remaining so till his discharge. Several sequestra were subsequently removed from the site of the fracture. The Thomas splint was retained longer than usual owing to the condition of the fracture. He was discharged from hospital on February 24th. The patient now walks with a stick, and can flex his knee to a right angle.

CASE III.

A. R., a boy aged 11 years, was admitted to the Royal Infirmary on January 29th, 1920, with a dirty wound over the left knee joint, the result of a fall some days earlier. The wound did not appear to communicate with the joint, and he was sent home on February 2nd.

He was readmitted to hospital on February 16th. The knee was painful and swollen, and his temperature was 103.6 F. A ray examination showed no bony injury. The joint was aspirated on several occasions, and pus cells and streptococci were found present. As the joint repeatedly filled up and his temperature reached 104 F. the procedure described was adopted. The temperature dropped slowly and his condition rapidly improved. He was discharged on March 24th, the wounds being healed. The knee joint could be flexed about 45 degrees at that time. I have not seen the boy since that date.

CASE IV.

E. J., a boy aged 15 years, was admitted to the Royal Infirmary on February 3rd, 1921, suffering from acute osteomyelitis of the right tibia. Operation was carried out for this condition the same day, when the medullary cavity of the tibia was freely opened.

His progress continued satisfactory till March 1st, when the right knee-joint was found to be painful and swollen. Aspiration of the joint showed pus cells and streptococci to be present. The joint was therefore opened, washed out, and bipp applied, the limb being placed in a Thomas splint. The right elbow-joint also became involved and was treated on similar lines, lateral incisions being made either side of the olecranon.

A streptococcal vaccine was prepared from the pus by Dr. G. E. Lovelady, and injections given at regular intervals. This additional treatment contributed in no small degree to the successful result of the case. His subsequent progress was satisfactory, both joints quickly cleared up, but the wound of the tibia continued discharging pus. He is still receiving hospital treatment for this condition, and massage to the affected joints, which are slowly improving.

CONCLUSIONS.

1. The insertion of drainage tubes into the knee joint is not only unnecessary, but harmful in acute arthritis. If thorough irrigation with saline is carried out at an early stage, the synovial membrane lining the joint can safely overcome the septic infection aided by the application of bipp.

2. The joint cavity must be left open after the irrigation, otherwise the pus will reaccumulate under pressure, and, burrowing through the capsule, spread in the fascial planes.

3. Extension must be applied to the limb during the early stages to separate the articular surfaces and prevent erosion of the cartilages at the site of pressure.

4. Mobilization and massage must be instituted as soon as the stage of active inflammation has subsided, usually within fourteen days.

THE RESULTS OF NINETY-EIGHT CASES OF NERVE SUTURE.

BY

PAUL G. DANE, M.D. MELB.

In the *Medical Journal of Australia*, July 26th, 1919, I reported the results of my observations, extending over two years, on 63 cases of nerve suture, comprising 23 cases of suture of ulnar nerve, 14 of median, 12 of musculo-spiral, 13 of sciatic, and one case of musculo-cutaneous nerve of arm.

This number has been amplified since by the addition of other cases, and the original cases have been revised, so

that 93 cases of nerve suture are now presented, arranged in six series as follows:

1. Ulnar series	35 cases
2. Median series	20 "
3. Musculo-spiral series	15 "
4. Sciatic series	22 "
5. Musculo-cutaneous	1 "
6. Brachial plexus	5 "
	93 "

These cases are entirely unselected—they are taken seriatim from the card records of the Massage Department, No. 5 Australian General Hospital, Melbourne, and all are the result of gunshot wounds, and have been under observation for from twelve to thirty six months.

The results of operative treatment on these various groups will now be given, and following that a more detailed study of them will be touched upon. On deciding as to recovery I have taken the amount of motor recovery as the standard, it being much more important from a practical standpoint, and much more easy to determine accurately and quickly than sensory return; but as a rule sensory recovery was more complete and earlier than return of motor power.

The groups of cases are divided into four classes: Perfect results; Good; Fair; and Bad results. Under the column "Perfect" are grouped cases that have gone on to full motor and sensory recovery, even though the muscular power be feeble, as it is in a great many cases; under "Good" are found cases where there has been a recovery of muscles subserving gross movements, such as the long flexors in the forearm or the gastrocnemius or tibialis anticus in the leg, but where the muscles subserving finer movements, such as the intrinsic muscles of the hand, have not recovered. In my former paper I also included under this group cases that had a probability of further recovery, but it is hardly necessary to do this now, as the cases have been under observation so much longer. In the group labelled "Fair" are cases that have recovered to a more limited extent, and under "Bad" are cases that have not recovered any function.

Table showing Results in 93 Cases of Nerve Suture.

Nerve	Perfect.	Good	Fair.	Bad.	Total.
Ulnar	8	12	3	12	35
Median	5	4	5	6	20
Musculo-spiral	5	3	3	4	15
Sciatic	6	4	2	10	22
Musculo-cutaneous	0	1	0	0	1
Brachial plexus	1	1	2	1	5
Total	25	25	15	33	93
Per cent.	25.5	25.5	15.3	33.6	

By this table it is seen that 25.5 per cent. of the cases have gone on to perfect recovery, whereas 49 per cent. (the last two groups) are practically failures, but if we add together the first two columns as constituting good results we get 51 per cent. of good results as against 49 per cent. of bad results. However, I do not think that we can regard the results purely in this manner, as each individual case must be considered by itself; for instance, in the "Perfect" group of 25 cases only 11 cases regained full motor power—by that I mean regained a perfectly useful limb of the same functional capacity as before the wound; in the majority of cases many of the muscles that regain movement remain weak and atrophic.

The explanation of this fact involves many factors, such as concomitant injury to blood vessels, other nerve trunks, sepsis, and improper pre-operative and post-operative treatment—probably more to this last factor than anything else.

A few of these points are now indicated:

Ulnar Nerve Series.—Sixteen cases had also an injury to the median nerve, and one of these had in addition the musculo-spiral severed. Three of these had also the main artery ligatured.

Median Nerve Series.—Nine of these had the ulnar nerve injured, and one had in addition the musculo-spiral nerve severed; one case had both main arterial trunks ligatured.

Sciatic Nerve Series.—Ten of these were suture of external popliteal and the remainder were cases in which the whole sciatic had been severed. Of the former four gained a perfect result, and of the latter only two gained a perfect result.

Throughout the whole six series of 98 cases the only ones which had had any proper pre-operative or post-operative treatment by means of splints were a few of the musculo-spiral cases. In the great majority of cases it was not until patients came to our department that any postural treatment was adopted, and in many cases months elapsed between the wound and operation, and between the latter and admission to our department. The results of these six series of cases, aggregating 98 in all, do not agree with some of the glowing reports found in the literature. Professor Tinel in his book estimated that 85 per cent. of his cases had recovered or would recover. He of course acknowledges that all were under the best circumstances for recovery, whatever he means by that. Even taking the most liberal estimate of my cases we find that 51 per cent. represents the standard of recovery, and I feel sure that this figure greatly exceeds the real truth, especially if one regards recovery from the point of functional usefulness apart from mere academic recovery of muscle movement. I have erred on the liberal side in estimating recovery, and do not think that many of the cases (if any) in column "Good" will progress any further.

The results on the whole, then, are in some measure disappointing, considering the tremendous amount of regenerative power that the axis cylinders possess, probably more than any other tissues in the body; and yet the results are encouraging when one considers the many unfavourable factors militating against success in almost every case. Some of these factors have been mentioned above and need not be here reconsidered. The question of the lapse of time between receipt of injury and suture of nerve is very hard to evaluate. Some cases that were operated upon a few hours after being wounded did badly, whereas others which were not operated upon for months did well. Of the operative technique I cannot speak, as cases were done by many different surgeons, but I feel sure that it was good, as the majority were operated upon by surgeons whose ability is well known.

A big factor associated, as I have before stated, with practically every case has been the neglect of pre-operative and post-operative postural treatment by means of splints, etc. This neglect, I feel sure, has been responsible for most of the failures, especially with regard to the delicate intrinsic muscles of the hand. It is not to be expected that these muscles will recover so easily as the other larger muscles. Being situated more distally they are at a marked disadvantage from the point of view, first, of time required for processes to grow into them; secondly, the small size of the nerve trunk as it spreads peripherally renders the march of the new processes more difficult, and these small muscles are pulled out of position very easily by the contracture of antagonistic groups, and this with such delicate organs must greatly injure them.

With regard to post-operative treatment, I have not been much impressed with electrical methods, and in future I shall not employ them at all, or only to a very limited extent. It is impossible to know exactly what one is doing in many cases, and probably more harm than good results from violent shocks to sick muscle engines. Scheft showed in 1851, and Professor Langley confirmed his results (*Journal of Physiology*, July, 1916), that a denervated muscle is in a state of fibrillation. It seems to me that, such being the case, it is the height of absurdity to send comparatively violent electrical stimuli into a muscle in a condition like this. There is one thing above all that it requires, and that is rest—complete rest—and this can only be done by the application of appropriate splints, so as to control all joints over which the muscle acts, thus placing it in a condition of maximum relaxation. This is difficult to obtain fully in many cases, but it is the end to be aimed at, and ingenuity and experience can enable one to design splints, etc., to do this.

Hartman and Blaky, in an extensive research on the subject reported in the *Journal of the American Medical Association*, March 22nd, 1920, performed a series of experiments on rabbits, denervating the muscles of the hind legs, and then applying the recognized forms of treatment. They came to the conclusion that neither massage nor

galvanism had the slightest effect in preventing atrophy of muscles—the only positive conclusion that they came to was that the more perfect the coaptation of the divided nerves the more perfect was the result. They did not try the effect of splinting or postural treatment at all; in fact, they used passive movements daily, which to my mind rather vitiates their results, as, unless those movements are done very carefully, stretching of the sick muscle results and does harm, as W. C. Mackenzie has shown in his work on the paralyses following acute anterior poliomyelitis.

I am convinced that we have as a profession not yet grasped the overwhelming importance of rest—perfect rest—and gradual re-education to muscles that have been injured by denervation from whatever cause. In Australia we should have wakened up to this problem much sooner, as it has been preached to us for the past ten years. It must be emphasized that a denervated muscle is a sick muscle (sick unto death almost), and that we must apply to it the cardinal principle that runs all through our treatment of almost every pathological condition. This applies much more forcibly to such small muscles as the intrinsic muscles of the hand and the muscles of the face, more especially as these are always placed at a great disadvantage by the stretching of the antagonistic groups.

As regards recovery of sensation, my experience has been that this is practically never perfect, but in a great many cases some recovery of sensation returns, and this of itself is of great advantage to the individual, protecting him from burns and other injuries, and also indirectly leading to an increase of nutritional activity.

FIVE CASES OF RAT-BITE FEVER:

TWO CASES TREATED SUCCESSFULLY BY
NOVARSENOBILLON.

BY

F. W. BURTON-FANNING, M.D. CAMB., F.R.C.P.,

HONORARY PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL.

JUDGING from my experience, I am inclined to think that this remarkable disease is not so rare as is generally supposed. It has been well recognized in Japan since 1899, and some 40 cases have been recorded there. But it was not until 1910 that Sir T. J. Horder¹ published an account of three cases of rat-bite fever, stating that they were "instances of a disease hitherto undescribed, at least in this country." Since then single cases have been recorded by Dr. G. S. Middleton,² by Dr. R. W. Cruickshank,³ by Dr. J. O'Carroll,⁴ by Professor R. Tanner Hewlett and Dr. G. H. Rodman,⁵ by Dr. F. Nicholson,⁶ and by Dr. J. H. Nixon.⁷ Dr. A. G. Atkinson⁸ had one case under his own observation, and collected the particulars of 5 other cases, which he published for the first time, together with an excellent account of what is known about this disease.

Since 1897 I have seen five patients suffering from rat-bite fever, all of whom came from different parts of Norfolk. In addition, I have been told of a few other cases, some of which at least were probably instances of the same disease.

Three of my patients were in the Norfolk and Norwich Hospital, one was seen with Dr. G. Calthrop in the Wells Cottage Hospital, and the fifth was seen in consultation with Dr. W. Royden, of Fleggburgh. The cardinal features of the disease were present in all my cases, and are so characteristic that if the existence of such a malady is known its diagnosis is easy. There are also a number of less constant symptoms; these are set out by Dr. Atkinson, and I propose only to refer to some of them and to give briefly the notes of three of my cases. The mortality of rat-bite fever in Japan is stated to be 10 per cent.

The fifteen published cases in Great Britain and my own five cases all eventually recovered. It has been noted as one of the features of the malady, as seen in this country, that there is a tendency to its spontaneous subsidence, but its course may be a very long one and the patients are usually gravely ill. In different cases the duration has varied between a few months and as many years. Until recently it was agreed that no treatment was of any avail. The periodic attacks of fever have led to the trial of large doses of quinine, but this and a number of other drugs—

CASE I.—Novarsenobillon 0.45 gram was injected on November 25th.

including atoxyl—have been found useless. Now, however, we have information on the organism which causes the disease, and the last two patients had the benefit of a rational method of treatment which promises to be a cure.

Many different micro-organisms had been found in the past by some observers, and their presence refuted by others. Horder's cases were thoroughly investigated, but with negative results. From two of my patients the blood, and fluid from puncture of inflamed skin in one, have been examined by Dr. G. P. C. Claridge, but he found no organism, and there was no growth on culture media. Other observers have also agreed that there was nothing to be found in the blood or elsewhere.

I am indebted to Dr. Atkinson for having my attention called to a publication by Mr. A. G. R. Foulerton,⁹ describing *Spirochaeta morsus muris*. This organism has been found by Japanese investigators "in the blood of one, out of forty-three apparently healthy house rats examined. Inoculation of a white mouse with the blood of this rat was followed by an infection identical with that produced by inoculation with material from human cases." The negative results obtained by ordinary examination and by culture of the patients' blood are explained, for the demonstration of the spirochaete by direct examination is stated to be difficult. But if white mice are inoculated with the blood, or with exudation from the skin, or with liquid from the affected glands of a human patient suffering from rat-bite fever, the spirochaete can be demonstrated in the mouse's blood. Mr. Foulerton kindly undertook to make some inoculation experiments with the blood of Case III. Six guinea-pigs were inoculated with blood drawn during two bouts of fever, four of the animals have remained quite well, and in none of them have any spirochaetes been detected. Mr. Foulerton writes: "But the clinical evidence leaves no doubt whatever as to the nature of the case, and it appears that others have found the experimental confirmation, by inoculation with patient's blood, somewhat uncertain of result."

Before this spirochaete had been identified as the cause of rat-bite fever its treatment with salvarsan had been advocated by S. Hata.¹⁰ He used salvarsan in eight cases. Five were immediately cured, a sixth case was benefited, and the remaining two cases improved temporarily, but relapsed later. In regard, however, to these last two cases, the author explains that they did not receive a large enough dose. In Case I of mine an intravenous injection of novarsenobillon 0.45 gram was given by Dr. Claridge. As will be seen from the chart an immediate effect was produced, and for the next five weeks the patient had no recurrence of the febrile attacks. Moreover, all the local inflammatory manifestations at once began to clear up, and his general condition to improve markedly. So he returned home to complete his convalescence. Five weeks later it appeared, however, that he was not quite cured. There occurred a rise of temperature to 101.4° and a transient erythema on the limbs. Dr. G. C. Gaynor, under whose care he was at home, gave him a second intravenous injection of novarsenobillon 0.6 gram, and the temperature remained normal for the next seven weeks, while he continued to regain weight and strength and was able to resume work. Two more similar doses were given at intervals of two and three weeks, as the temperature again rose on single occasions to 100°, with reappearance of the rash. Three months after his first dose, which was followed by subsequent injections at irregular intervals, the patient appears finally cured and has regained twenty-two pounds of weight.

In Case III the first injection of novarsenobillon was followed by a similar abrupt cessation of fever. Three

more doses were given at regular intervals of a week, but from the time of the first injection he made an uninterrupted recovery as regards every feature of his illness.

If a conclusion may be come to from the experience of these two cases, I would say that a single dose of novarsenobillon puts a stop to the recurring attacks of high fever, and reduces all the inflammatory affections of lymphatics and skin. But, as in the case of *Spirochaeta pallida*, the injection must be repeated at regular intervals of a week to complete the cure.

I will give briefly the notes of three of the patients:

CASE I.

I. H. B., aged 54, was admitted into the Norfolk and Norwich Hospital, under my colleague Dr. A. J. Cleveland, who was kind enough to transfer him to me for the purpose of this communication. He had never been ill previously. On October 3rd, 1920, while rat catching, he was bitten on the left index finger by a ferret which had killed and partly eaten several rats. There were four small punctures on the finger which quickly healed, and never showed at all after the first few days. On October 15th he began to feel ill, and the left axillary glands enlarged. A few days later he was seen by Dr. Gaynor, who noted lymphangitis and lymphadenitis of the left arm, with areas of inflamed skin in other parts, and attacks of fever every few days. On October 25th, on admission to hospital, the patient was obviously very ill; he had a muddy complexion, and was heavy and prostrate. On examination the striking feature was lymphangitis. This could not be traced directly from the bitten finger, but was most marked over both shoulders. Coursing from the tops of each shoulder, over their anterior aspects to the axillae, were three or four parallel red lines. These could be seen and felt to be of about the thickness of the stem of a clinical thermometer. The glands in the right axilla were less enlarged than those in the left axilla, but the lymphangitis was equally marked on the two sides, and less obtrusive affection of the vessels was seen in both arms. Another phenomenon was the occurrence of circular patches of erythema on the forehead, the face, the chest, the upper abdomen, and the forearms. The larger of these were about an inch in diameter; they were red in colour, with a yellowish inner ring. Some were so prominent and swollen as to suggest the presence of pus. With each febrile attack these inflammatory affections of the lymphatics and of the skin would become aggravated and fresh lesions would appear. My patient had a little diarrhoea for a few days, and during each attack of fever he complained also of much soreness and dryness of the throat, where some congestion was apparent.

For the first three weeks of the illness he had epididymitis of moderate degree on the left side, which gave him some pain during its existence, but which subsided readily while the other symptoms were at their height. This is a complication which I have not found recorded by others, but it is interesting to read in Foulerton's paper that on *post mortem* examination of a patient in Japan there was found a single spirochaete in the testicle, while numbers were found in the kidneys and suprarenal glands. The striking characteristic of rat bite fever is indicated in the accompanying chart. With almost the punctuality of malaria, every few days the temperature rose sharply, and there was an exacerbation of all symptoms and signs. The fever persisted for from a few hours to a couple of days, and then the temperature became lower and remained so for a certain number of days. The afebrile intervals lasted about three days, and there was a tendency for these to lengthen as the illness went on. In other cases these intervals have extended to a week, but periodicity has been equally marked. This patient's treatment by injections of novarsenobillon has been already referred to.

My first case of rat-bite fever occurred in 1897. Its true nature was not recognized at the time, it was diagnosed as ague and was referred to by Professor G. H. F. Nuttall¹¹ as the last case of indigenous ague in England. I am now, however, satisfied, from looking up the excellent

CASE II.

notes of the house-physician, Dr. E. S. Verdon, that in reality it was a case of rat-bite fever in a man who had once been subject to malaria.

CASE II.

W. A., aged 49, was admitted under my care into the Norfolk and Norwich Hospital on December 11th, 1897. He had always lived in Acle, which stands in the centre of a district known for its rivers, broads and marshes, and where *Anopheles maculipennis* is still constantly found. At the age of 10 he had ague, but no mention is made in the notes of recurrence. Nine weeks before coming under my care he had been bitten by a rat in the palm below the right wrist. A local abscess formed, and there was lymphangitis up the arm. An incision had been made, but the skin remained red and indurated. Lymphangitis of the right arm and forearm was the conspicuous condition, but he also had patches of erythema on the other arm. He had paroxysms of fever, shivering and sweating at intervals of from two to four days, along with which it is recorded that the inflammation in the arms increased. Dyspeptic symptoms with vomiting occurred during the whole illness. It was in the notes that quinine in doses of 5 grains three times a day averted the attacks of fever, the last of which occurred a few weeks after the bite. Many examinations of his blood were made by Dr. S. H. Long, who at length found a few malarial plasmodia. This finding was confirmed by Professor Nuttall, who saw the slide, which is still in Dr. Long's possession.

In this case there is the history of a rat bite followed after an incubation period by lymphangitis and widespread

surface of the body, of the face, and of the limbs was covered with an extensive papular rash. This was darkish red in colour and with each attack of fever the papules enlarged and fresh ones appeared. The spleen was just palpable and remained slightly enlarged during the illness. On the palmar surface of the right thumb was a sore as large as a florin; this was covered by a yellow slough and surrounded by red skin. There was marked lymphangitis from the thumb up the forearm and the axillary glands on the right side were enlarged and painful.

A blood count showed 11,100 white cells and no eosinophilia. The attacks of fever are represented in the accompanying chart. As these came on the patient complained of severe headache, he felt cold, then followed profuse sweating and occasional vomiting. On one night he was delirious with the fever.

On the evening of the day following his first injection of novarsenobillon the temperature fell, and there was no further recurrence of the attacks of fever, which had previously appeared with more or less regularity every forty-eight hours. Moreover, from this time the rash and the lymphangitis began to fade rapidly and the spleen was no longer palpable. He quickly regained the appearance and feeling of health, and his complete recovery was uninterrupted. I believe that this result was due to his receiving three further doses of novarsenobillon at intervals of a week after his first injection, and without waiting to see if any relapse took place.

In my other two cases the illness was of considerable

CASE III.

patches of erythema. The paroxysms of fever were not quite punctual in their recurrence and were not controlled by quinine. But the notes quote the patient's statement that they resembled the attacks of ague from which he had definitely suffered thirty-nine years previously, and plasmodia were identified by Nuttall and Long. The incidence of rat-bite fever in an old malarial subject, who still harboured the organism of the latter malady, is most remarkable, because the resemblance of the two diseases has been always referred to by writers on rat-bite fever. The temperature chart from the hospital case-book is appended.

CASE III.

S. H., aged 38, was admitted into the Norfolk and Norwich Hospital on March 14th, 1921, under the care of Mr. C. Noon, on account of a septic sore on the thumb with attacks of high fever. I am indebted to Mr. Noon and to his house-surgeon, Mr. P. Murphy, for the following notes and for opportunity to watch the case. The patient was bitten by a rat on February 15th and the small wound on the right thumb healed rapidly under local treatment. About twelve days later there were pain and tenderness at the site of the bite, which increased during the next few days and then extended up the forearm to the axilla. On March 3rd the thumb was incised by his doctor, but no pus was found. Headache, sleeplessness, and slight sore throat, with increasing feverishness, were complained of, and he was sent to the hospital. There he presented the aspect of acute illness, with flushed face and injected conjunctivae. The

severity and was marked by the same type of intermittent fever, extending in one patient over three months and in the other over six months. Two and three weeks elapsed between the bite of the rat and the onset of symptoms. In both patients the wound had healed in the interval, and there was no suppuration. One of the patients had much lymphangitis and lymphadenitis, but the other had only an eruption of boils on the skin. In one of Atkinson's cases the illness was followed by a series of boils.

Without recounting my cases at greater length, I would say that the points of rat-bite fever are as follows: The illness is caused by the bite of a rat, or, as in one of my cases and in one of Atkinson's, by the bite of a ferret, or, as in another of his, by the bite of a kitten—all these animals having just bitten the body of a rat.

There is an incubation period, whose duration in my five cases was from 12 to 21 days, which corresponds with that observed by Atkinson. But the incubation period may extend to two months, as in the cases of Hata and of Hewlett and Rodman. During this period the wound may or may not have healed, and the onset of illness may be associated with fresh inflammation of the wound or of the scar.

Fever of a characteristic type has been the cardinal feature of all cases in this country, though it should be

mentioned that an afebrile form of the disease is described by Japanese writers. There are periodic sharp rises of temperature, which may be accompanied by a rigor. The intervals of normal temperature last three or more days, and the attacks come with some punctuality. With each attack the local inflammations are increased, and there are usually such general symptoms as great malaise, prostration, pains in the limbs, vomiting, diarrhoea, and soreness of the throat.

Swelling of the tongue and definite swellings in different muscles characterized two of Atkinson's cases. The virus of the disease appears particularly to affect the lymphatic system. The constant presence of intense lymphangitis is noted by Japanese writers, and this was the striking feature in four of my cases. It was present in half the cases collected by Atkinson. Enlargement of lymphatic glands has been more common in English cases, though in one of Horder's cases this was absent. Suppuration is often thought to be threatening, but this does not occur except rarely in the wound.

A form of erythema was present in two-thirds of Atkinson's cases and in four of my five cases. Of Horder's three cases it was absent in one, where the only local affection was firm oedema of the bitten arm. In one of my patients the inflamed patches were suggestive of erythema nodosum, but they were more raised, and the only colour effect was the presence of a concentric yellowish ring within the border of the circular red patch.

An Italian case of rat-bite fever, after two years' illness developed retro-ocular cellulitis and exophthalmos. Albuminuria with dropsy has been recorded in several cases; one of my patients had oedema of the feet towards the end of his illness, but there was no albumin in the urine. The occurrence of epididymitis in one of my patients has been mentioned, while in another there was slight but palpable enlargement of the spleen.

Leucocytosis is present as a rule, and increases with each attack of fever. But O'Carroll's case had marked anaemia and a white cell count of 7,200. In this case and in an Italian case eosinophilia was present, though in others its absence is noteworthy. Dr. Claridge's examination of the blood of my patient, I. H. B., gave 23,350 leucocytes with the following differential count: Polymorphs 91.7 per cent., transitionals 1.6 per cent., lymphocytes 5.8 per cent., eosinophils 0.9 per cent.

Rat-bite fever is a serious illness, as testified to by a medical man who himself suffered from it in 1896. He was seen by several eminent doctors, and thought then to have some form of blood-poisoning. Dr. G. Master's case is now included in Dr. Atkinson's account of rat-bite fever, and he writes to me:

"I was away from work for seven months and did not feel fit for eighteen months after the start of my illness. The wasting was extreme; I could make my two hands meet round my waist, and at one time I could not turn myself in bed. Treatment did not seem to help in any way."

It now appears that rat-bite fever can be added to the list of diseases for which the cause and the efficient remedy have been found.

THE TREATMENT OF CUTANEOUS ANTHRAX.

BY

W. H. OGILVIE, M.A., M.Ch., F.R.C.S.,

AND

A. W. HALL.

[From the Surgical Department, Guy's Hospital.]

AN editorial article in the BRITISH MEDICAL JOURNAL of February 5th, 1921, on the question of anthrax in shaving brushes was concerned mainly with the source of the infected supplies and the methods of dealing with them, but there was a short discussion on means of treatment, in which it was stated that excision of the pustule is no longer recommended. In response to an inquiry the Editor kindly referred us to Circular 172 issued by the

Ministry of Health, January 28th, 1921, from which the following paragraph is quoted:

"Treatment of Persons Infected."

"In general, the best treatment for a case of anthrax is physiological rest of the part affected, combined with intravenous injection of anti-anthrax serum—60 to 80 c.cm. on the first day and 60 c.cm. on the day following, if there has been no reaction (shown by a rise of temperature) and the general condition has not improved. Excision is unnecessary. Subcutaneous injection into the abdominal wall of 30 c.cm. has apparently been successful in many cases, repeated, if necessary, on successive days. Difficulty is always met with in estimating the efficacy of different methods of treatment of a malady such as anthrax, which is capable of undergoing spontaneous cure."

Inspector of
Forms of treat-
the erysipela-
nclasion:

Treatment.	Cases.	Deaths.	Mortality per cent.
Serum only	200	8	4.0
Excision only	377	41	11.1
Excision and serum ...	171	25	14.6
No special treatment ...	29	14	48.3
Total	830	91	11.4"

At Guy's Hospital, where a few cases of anthrax are admitted every year, and where the possibility of infection is always present in the minds of those in charge of the surgery owing to the special character of the industries of the borough, the practice for some time past has been to combine excision with serum treatment. It is therefore interesting to compare our figures with those quoted above. We have taken the years 1909 to 1919 because it was only in the year 1910 that serum began to be used regularly. Records for 1918 are unfortunately incomplete. Since 1910 the majority of cases have been treated both by excision and serum, but it is only since 1916 that the serum has been given in doses as large as those recommended in the above circular. In going through the reports all those cases have been omitted where adequate details confirming the diagnosis were absent, or those in which anthrax bacilli were not discovered, though on clinical signs they have been classified as anthrax.

Treatment.	Cases.	Deaths.	Mortality per cent.
Serum only	4	1	25.0
Excision only	6	1	16.6
Excision and serum ...	37	3	8.1
Treatment not specified ...	1	1	—
Total	48	6	12.5

The number of cases in this series is obviously far too small to allow conclusions to be drawn from them with any convincing degree of certainty. The gradation of falsehoods into three classes, of which the superlative is "statistics," is a familiar one in political discussion; but it applies with even more force to statistics in medicine or surgery, for the sources of error are innumerable. Successes are nearly all published, very often before they have stood the test of time; failures are as commonly buried in oblivion. Very few series are large enough to exclude the element of chance. But, apart from the factor of the individual and the allowances that must be made for enthusiasm, many other sources of error come in. One is accuracy of diagnosis. Were all cases admitted to Guy's Hospital as anthrax on clinical evidence and not confirmed by discovery of the bacillus to be included, the mortality of the series would be very materially reduced.

This factor of accuracy in diagnosis is especially important in all statistics bearing on the mortality of the surgical treatment of exophthalmic goitre. Another factor is the severity of the type of case which is admitted to any institution. If the death rate from fractures of the base of the skull at different hospitals be examined, it will be found to range from about,

CRYPTOGENETIC PNEUMOCOCCAL SEPTICAEMIA.

50 per cent. in some places to 10 per cent. in others. This discrepancy is merely due to the fact that the first hospital is in the centre of an industrial district where severe accidents are common, the second in a scattered neighbourhood with poor facilities for transport, so that most severe head injuries die before reaching hospital. In fracture of the base it is the severity of the injury and not the line of treatment adopted which is the chief factor in determining the result. For this reason the comparison of statistics published by different surgeons during the war is valueless unless the exact conditions are known. The mortality in gunshot wounds of the abdomen, for instance, might be expected to be small at a base hospital, much greater at a casualty clearing station, and still greater at an advanced centre, merely because distance automatically sorted out the severe cases.

If we examine critically the figures quoted from the circular of the Ministry of Health, it is difficult to agree with the conclusion that excision *plus* serum, is very fact that the mortality after excision alone, greater than that for either serum alone or excision alone, shows that other factors are at work. Were excision a harmful factor (as it might be, owing to disturbance of the protective barrier set up by the tissues), the mortality of the cases treated by excision alone should be greater than that of the untreated cases. But, leaving this argument on one side, it is absolutely certain that, were excision harmful, the cases treated by excision *plus* serum. It is worse than those treated by excision *plus* serum. It is unthinkable that a harmful factor should be either a by itself than when combined with a beneficial factor. If, then, excision is not harmful, it may be either a valuable or a neutral factor in treatment. The facts that stand out from the report are, first, that over 70 per cent. of the 800 cases have been treated by excision, which seems to point to a fairly general belief in the efficacy of this procedure; and, secondly, that excision by itself has reduced a death rate of 48.3 per cent. to one of 11.1 per cent. without the use of serum in addition. It seems pretty certain that the mortality given for the cases in which both methods were employed involves other questions in addition to that of the treatment adopted. We suggest that the cases treated by serum only would probably include all very slight cases, and all doubtful pustules in leather workers which resembled anthrax lesions but were not proved to be so, or did not seem severe enough to justify excision. In such cases it would be only right, in view of the danger, to give a prophylactic dose of serum. Late cases of genuine anthrax in which a natural cure was being effected would probably also be treated with serum only. On the other hand, extensive lesions of a fulminating type would nearly all come into the class treated by both methods.

It is probable that the series from Guy's Hospital, though small, gives a much fairer picture, and that the death rate when both methods are combined is notably lower than when either is used alone. In the early stages of anthrax the bacilli are limited to the pustule and its immediate neighbourhood. Excision by itself will assure a cure in about 90 per cent. of cases in a disease having a natural mortality of something like 50 per cent., while a natural mortality of something like 50 per cent., while serum at best cannot be relied upon to avoid a fatal issue in all cases. In view of the danger of anthrax and the local nature of the infection in the early stages, it therefore appears to us to be the wiser course to combine the two methods, which are both known to be good and which cannot be mutually antagonistic, and thus to give the patient every chance. Little or no importance can be attached to the circumstances be attached to the resulting scar. We consider, then, that the combination of excision and serum treatment as used at Guy's Hospital is probably the most rational and the safest course in all cases of cutaneous anthrax which have not reached the stage of a septicaemia.

The Journal of the American Medical Association announces that Brigadier-General Charles E. Sawyer, personal physician to President Harding, has been assigned a suite of rooms in the State, War, and Navy Building, formerly occupied as headquarters of the Army, from which he will direct the establishment of a department for the arrangement of better hospital facilities for disabled soldiers and sailors.

CRYPTOGENETIC PNEUMOCOCCAL SEPTICAEMIA.

BY
SIR JOHN LUMSDEN, K.B.E., M.D.,
PHYSICIAN TO MERCER'S HOSPITAL, DUBLIN.

CRYPTOGENETIC SEPTICAEMIAS are of particular interest to the physician, and, as a search of the literature on the subject shows few cases recorded of pneumococcal septicaemia without any evidence of a focal lesion or portal of entry, the following brief notes of a case recently under my care is, I think, of sufficient interest to record. That a blood infection occurs in acute pneumonia in a large percentage of cases, and that the pneumococcus can be cultured from the blood in many cases has been demonstrated in an extensive series of investigations. It has been stated by one observer that blood cultures give positive results in 50 per cent. of fatal cases; others have suggested invasion of the blood by pneumococcus to be a constant condition. Pneumococcaemia, however, without distinct localizations, has, Osler states, been reported by Wright, Stokes, Pearce, Flexner, Hektoen, and others. The following case would, therefore, seem to be of the cryptogenetic variety.

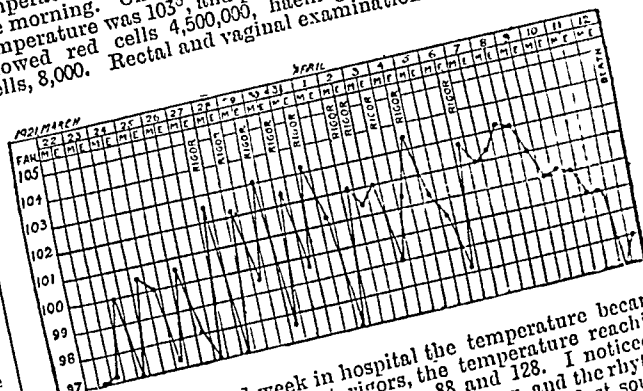

Mrs. S., aged 48, came to see me about March 8th, 1921. Her symptoms were of an indefinite character. For some weeks she had been feeling unwell, had been losing energy and some weight, appetite was poor, and she suffered from restless nights, shivering fits, occasional diarrhoea, and persistent polyuria. The temperature was normal and the pulse small and of low tension. A hasty examination of chest and abdomen failed to elicit any definite abnormality. She had no cough or any symptoms referable to her chest. She complained of lumbar pain radiating down the back of the thighs, and also some nausea. There was a history of slight discharge from the left ear, lasting a few days, some short time before, but it apparently cleared up, and at present no otitis media was evident. I examined the urine next day, specific gravity 1016, somewhat turbid, no sugar, a trace of albumin. As her family were becoming increasingly anxious on account of her lack of energy, progressive weakness, and shivering attacks, I was asked to admit her to Mercer's Hospital on March 22nd, 1921.

Condition on Admission.

General aspect: Face yellowish, cheeks flushed, eyes bright. Tongue perfectly clean, gums and throat healthy. Although thin, no marked emaciation. Pulse 100, regular. Blood pressure: systolic 90 mm. of mercury; diastolic 65 mm. of mercury. Temperature normal. Abdomen slightly distended, some relative rigidity below liver, and marked tenderness in both loins. Neither kidney was to be felt, but lower pole of spleen palpable. Reflexes normal. Urine: specific gravity 1020, acid, no sugar, slight amount of albumin; microscopically, some pus and epithelial cells, no casts, a number of mobile organisms, probably *B. coli*.

After-History.

During the following week her condition remained unchanged. She appeared apathetic, had no desire for food, had some nausea, was slightly constipated, and sleep was restless. Her temperature ran up to 101° at night, but returned to normal in the morning. On March 29th she had a distinct rigor. The temperature was 103°, and pulse rate 124. Blood examination showed red cells 4,500,000, haemoglobin 85 per cent., white cells, 8,000. Rectal and vaginal examination were negative.

During the second week in hospital the temperature became remittent, she had recurrent rigors, the temperature reaching 103°, and the pulse ranged between 88 and 128. I noticed a slight roughening of the first sound at the apex, and the rhythm became of a gallop type due to reduplication of the first sound. I thought, or possibly pericarditis. Tenderness and pain continued in the loins, and this was the chief complaint from the patient. There was no cough nor any abnormal lung sounds, although at the end of the second week some rhonchi and rales appeared, clearly due to a congestion or oedema. Petechiae appeared on the left breast, arms, gums, and the inside of the cheeks. She had fairly good sleep with the aid of bromidia.

Although the results of the first blood culture showed a bacteraemia it was not until the second examination that our pathologist, Dr. Pollock, satisfied himself that there was a pneumococcaemia. During the last week of the patient's illness she became wildly delirious, the sphincters became relaxed, and a slight systolic murmur was audible. She passed into a "typhoid state," and died at the end of the third week in the hospital, the temperature falling gradually to normal and blood pressure remaining persistently low.

Pathological Notes.

The following notes on the examination of the blood and on the post-mortem findings are by Dr. Pollock:

"As is my usual practice in blood culture, I withdrew 5 c.cm. of blood from a vein at the bend of the left elbow by means of a serum syringe, discharging the whole blood direct into a flask containing 50 c.cm. nutrient broth. I have found this method preferable to direct plating, as in the latter only a comparatively small amount of blood can be employed, and if the degree of infection be slight failure to cultivate may result. Unfortunately, the first flask became contaminated, and the second attempt was made a day or two subsequently. In this a practically pure culture was obtained of a Gram-positive coccus in pairs and chains, these latter being, in some instances, of such length as to suggest streptococci. Subsequent plate cultivation, however, reduced the chains, when present, to the short, straight diplococcus pairs characteristic of pneumococci; the vast majority of organisms, however, being diplococcal in arrangement and, in my opinion, of characteristic morphology. The numerous organisms present in the sections made subsequently from the thrombi present in the right auricle, *post mortem*, were seen in pairs, characteristically lancet-shaped, and were, in my opinion, characteristic pneumococci. The tendency of this organism in rich liquid media to approximate to a streptococcal type is, I think, noteworthy, being particularly noticeable during the somewhat recent severe epidemics of septic pneumonia."

The results of the *post-mortem* examination were as follows:

Thorax.—Pleura normal, no fluid in cavity.

Lungs.—Some slight emphysema present; oedema of both bases, no pneumococcal consolidation whatever.

Pericardium.—Distended with a clear yellow fluid (about 6 oz.); subpericardial petechiae, most marked over right auricle.

Heart.—Myocardium showed marked fatty infiltration, endocardium some relative mitral incompetence. Both aspects of tricuspid valve were covered with immense adherent vegetations. Growing from this evidently diseased valve up into the cavity of the right auricle, and almost entirely filling it, was a great *ante mortem* thrombus of a peculiar greenish tint. Biliary vegetations were also present upon the endocardium lining the right auricle.

Abdomen.—Liver, early "nutmeg" condition. Spleen: large, soft, pulpy, with petechial haemorrhages. Kidneys: Both showed an early chronic nephritis, more marked in the right. No suppurative condition. Other viscera apparently normal, and general condition of body good.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HERPES AND VARICELLA.

The interest at present shown in the relation between herpes and varicella leads me to send notes of a recent well marked case.

A woman, aged 53 years, was taken ill on April 8th, 1921, with pain low down on the right side of the chest and a feeling of general illness. When seen on the afternoon of April 11th a patch of herpetic vesicles was present; it developed, and ultimately a severe rash occupied the fifth and sixth right dorsal root areas. At first no eruption was to be seen elsewhere, but on April 14th there were two dozen macules, papules, and vesicles scattered over the trunk, shoulders, and buttocks. Three days later a vesicular eruption was present over the whole body, including the face; more than 100 vesicles were counted. The whole cleared away gradually, but severe pain persisted in the area of the "herpetic" rash.

George E. Elkington, M.B.Lond., F.R.C.S.

Newport Shropshire.

A CASE OF MYOCLONIC EPIDEMIC ENCEPHALITIS.

This case reported below occurred during the recent small outbreak of epidemic encephalitis in the city of Bristol, and was the only one that could definitely be classified as of the myoclonic type. The remainder of the cases seen, numbering between 20 and 30, were of the common cranial nerve palsy, lethargic type.

G. L., age 132, began to suffer from acute abdominal pain, without vomiting, on September 16th, 1920; next day he had diplopia, twitchings, and spasmodic movements of the body and limbs, and the pain was worse.

He was admitted to the Bristol General Hospital on September 19th as an "acute abdomen." The temperature was 102, the pulse 103, and the respirations 32. The tongue was coated. The eyes were prominent and blood-shot; the pupils were equal and reacted normally; there was marked nystagmus and left external strabismus. Speech was blurred with a tendency to stammer; he had never stammered before. There was no facial weakness. Spasmodic movements of arms and abdomen were frequent; all the abdominal muscles were involved and the movements were at times rhythmic and 20 to 30 to the minute. There was true abdominal rigidity; the knee jerks were very active.

The spasms ceased on September 20th. The patient, who was somewhat delirious, complained of abdominal pain. The leucocyte count was 13,600. The cerebro-spinal fluid was sterile; the number of cells was not increased, and there was a slight excess of globulin.

On September 23rd he was still boisterous and delirious; the right pupil was larger than the left, and there was facial paralysis on the right side and incontinence of urine. On September 25th he was much better, the temperature was normal, and he was quite rational; the right side of the face was still weak. On September 27th the temperature rose to 99.5 and he relapsed into delirium; no fresh paralysis developed. He died in coma on September 28th.

Post-mortem Examination.

There was some congestion, oedema and softening of the brain, and microscopical sections stained by methylene blue and eosin showed the following changes: In the cerebral cortex there were a few small haemorrhages into the pia mater, and a few of the nerve cells showed neuronophagia. The invading cells were basophil and considerably larger than the small round cells seen infiltrating the mid-brain areas.

In the mid-brain, at the level of the inferior geniculate body, general round-celled infiltration and perivascular infiltration was very dense, notably at the point of exit of the optic nerve. Some of the nerve cells were densely crowded with pigment granules. At the level of the nucleus of the third nerve and superior corpora quadrigemina, round-celled infiltration was present in moderate degree; perivascular infiltration was dense in parts, and some of the blood vessels were thrombosed. In sections through the red nucleus perivascular infiltration was fairly marked, but there was much less round cell infiltration. The nerve cells generally appeared degenerate.

In the pons at the middle of the fourth ventricle the same lesions were present in less degree. Several vessels were thrombosed, and neuronophagia was present. The upper half of the olivary nucleus in the medulla oblongata showed very little abnormality, and in sections of the spinal cord no macroscopic or microscopic lesions were noticed.

Compared with sections from other cases of epidemic encephalitis (cranial nerve palsy type) those described here show no lesion or distribution of lesions, at present recognizable by the means employed, that accounts for the variation in symptomatology. I am indebted to Drs. J. Odery Symes and Cecil Clarke for permission to publish these notes.

E. J. BRADLEY, M.D., B.Ch.Cantab.,
Late Senior R.M.O. Bristol General Hospital.

THE ACTION OF QUININE ON PREGNANT AND NON-PREGNANT UTERUS IN THE TROPICS.

In tropical countries some medical practitioners advise pregnant women to give up prophylactic doses of quinine as soon as pregnancy begins. The result is in many cases that chronic malaria causes severe anaemia and abortions; should the mother go to full term the children are badly nourished and have to be artificially fed owing to the poverty of the mother's milk, and unless both are removed from tropical regions there is great danger of the loss of their lives.

As with some women 5 grains of quinine cause contractions of the pregnant uterus and sometimes haemorrhage, I advise that the 5-grain prophylactic dose be taken in two doses of 2½ grains morning and evening, and in my thirty-two years' experience in Central Africa (11th deg. S. lat.) I have never seen a case where this has done any harm, and in nearly every case the 5 grains has kept the

women free from active malaria until the confinement. Then as the vital powers of resisting disease are much lowered by the excessive fatigue of child-bearing, it is necessary to give 10 grains (in very small doses) a day for five or six days, as very often, if not given, a severe attack of malaria will delay recovery with these doses.

I have never found quinine cause abortion. On the other hand, I have treated cases of abortion in native women (who do not take quinine), in which the frequent abortions were undoubtedly caused by chronic malaria, for when given the above prophylactic doses they were able to go to term and give birth to healthy living children.

With regard to the effect of quinine on the non-pregnant uterus, undoubtedly in a small percentage of cases it causes excessive and too frequent periods. Years ago I found that when 5-grain doses of quinine caused deafness or noises in the ears it was a sign that a smaller dose (3 grains) was sufficient as a prophylactic, and the majority of women under 120 lb. weight will, I think, find this smaller dose will keep them free from active malarial manifestations.

Recently I have treated this menorrhagia also as a sign that only smaller doses of quinine need be taken, and if the 5-grain prophylactic dose is necessary it should be taken in 2½-grain doses twice a day; the few cases treated, however, are not sufficient to lead me to any definite conclusions, and I would value greatly the experience of others in treating this very trying complaint.

Reports of Societies.

THE END-RESULTS OF PLASTIC VAGINAL OPERATIONS FOR GENITAL PROLAPSE.

THE first British Congress of Obstetrics and Gynaecology was held at Birmingham on June 3rd and 4th, when the following societies were represented: the Obstetrical and Gynaecological Section, Royal Society of Medicine; the Edinburgh Obstetrical Society; the North of England Obstetrical and Gynaecological Society; the Glasgow Obstetrical Society; and the Midland Obstetrical and Gynaecological Society.

The opening session in the morning of June 3rd was presided over by Professor H. BRIGGS, President of the Obstetrical and Gynaecological Section of the Royal Society of Medicine. Mr. CHRISTOPHER MARTIN, chairman of the Midland Obstetrical and Gynaecological Society, welcomed the Congress to Birmingham, and expressed the hope, which was echoed by various speakers throughout the day, that this Congress would now become an annual affair, and the chief and authoritative mouthpiece of British gynaecology.

The morning session was devoted to a discussion upon the operative treatment of genital prolapse, opened by Dr. W. E. FOTHERGILL and Dr. F. H. LACEY, of Manchester. The title of their paper was "The End-Results of Plastic Vaginal Operations for Genital Prolapse."

Dr. W. E. FOTHERGILL said that the discussion had originated at a meeting of the North of England Society held at Liverpool in December, 1918. Professor H. Briggs had described the treatment of a case of procidentia, in a patient aged 18, by a vaginal operation combined with ventrofixation, but advocated a modification of Gilliam's operation. Dr. W. F. Shaw deprecated abdominal operations for prolapse, preferring the vaginal methods used in Manchester. Other members urged that the end-results of these measures should be ascertained and published and a collective investigation by the society was suggested. At subsequent meetings this project was developed and the scope of the inquiry came in question. It was proposed to exclude all except cases of complete prolapse, but this was not thought feasible. The term "genital prolapse" had a fairly definite connotation all over the world; and medical men constantly used the word "prolapse" as including both so-called vagino-uterine prolapse and so-called utero-vaginal prolapse. In view of these considerations, it was decided at a Council meeting of the North of England Society in December, 1919, that the inquiry should include "cases of (1) cystocele, (2) rectocele, (3) prolapsus uteri, and (4) elongated cervix protruding from

the vulva"—namely, in two words, cases of "genital prolapse." At an ordinary meeting of the society in Liverpool in October, 1920, Dr. F. H. Lacey gave a preliminary report on traced cases operated on at St. Mary's Hospital, Manchester, during the years 1914-15-16. Subsequently it was arranged to defer the further consideration of the subject to this meeting.

Dr. Fothergill briefly indicated the steps by which he was led to his present technique, starting with his work in Edinburgh under Sir A. R. Simpson and David Berry Hart, who used at that time anterior and posterior colporrhaphies of moderate size, amputation of the cervix, and repair of the perineum. These were done as separate operations, and in some cases all four were used for one patient. Chromic catgut was the suture material, and the immediate results were good. On coming to Manchester in 1895 he found that, owing to the initiative of Professor A. Donald, surgical treatment of genital prolapse was already highly efficient; anterior colporrhaphy incisions were larger than those done in Edinburgh, and the whole thickness of the vaginal wall was removed. Donald had also combined the operation of posterior colporrhaphy with perineorrhaphy in a single operation done from above downwards.

Dr. Fothergill was gradually convinced by clinical experience that the uterus, vagina, and bladder were mainly kept in position by the lateral combinations of unstriated muscle and connective tissue known as the parametrium and the paracolpos, and this was demonstrated by him to the Royal Society of Medicine in 1907. The practical application was that anterior colporrhaphy could be improved by carrying the incision well up and out on either side of the cervix, fully exposing the paracolpos, so that closure of the wound must bring together in front of the cervix structures formerly at its sides. This he demonstrated to the Edinburgh Obstetrical Society in 1908. Subsequently he found that by carrying the incision round behind the cervix instead of in front of it, anterior colporrhaphy and amputation of the cervix could be conveniently combined in one single operation. When the wound was closed the cervical stump passed upwards and backwards so far that the uterus was left in a position of anteversion, thus dispensing with the need of excessive narrowing of the vagina. An improved technique and modifications were afterwards described in the BRITISH MEDICAL JOURNAL (April 12th, 1913); the *American Journal of Surgery* (May, 1915); and in the *Journal of Obstetrics and Gynaecology of the British Empire* (March and May, 1915). Dr. Lacey had traced as far as possible the after-histories of the cases treated by Dr. Fothergill at St. Mary's in 1914-15-16, so that since these operations were done periods varying from four and a half to seven and a half years had elapsed; no cases treated by mere perineal repair were included. One hundred and fifty-six patients replied to Dr. Lacey's letter of inquiry; of these, 150 stated without qualification that they were cured, while 6 did not. Of these 6, No. 1 had had three children since the operation, and the womb has gone down again; No. 2 said the "womb was not as it should be," but on examination no prolapse nor other abnormality was found; No. 3 had chronic bronchitis and asthma, and the operation was therefore a failure from the start; in No. 4 the uterus was in good position, but there was some vaginal prolapse; No. 5, a case of rectocele only, had an instrumental labour and was torn badly, and there was a slight recurrence of rectocele; and in No. 6 nothing was found on examination, but she said she still had pain at times. This gave 97½ per cent. of cures. As to the ages of the patients, about one-third had passed the menopause.

In 124 cases combined amputation of the cervix with anterior colporrhaphy was done, while in the remainder the cervix was retained. Thirty-two were examples of elongated cervix with inversion of the vaginal walls from above downwards. It would be unreasonable to expect that the new pelvic floor should always stand the test of labour; the original pelvic floor did not always do so. From this point of view it was of interest to note that 21 of the women under 40 and 3 of those over 40 had since borne children, and 2 others were now pregnant; and, of these 26, 23 had had the cervix removed by the combined operation. To the 24 patients 30 children had been born; 23 labours were natural and 7 instrumental, but in no

case was labour obstructed. Four patients had had two labours each with no recurrence of prolapse; 17 one labour each, with no recurrence, and one was badly torn with a slight recurrence of rectocele. Another had one labour and said that the womb fell slightly when she was tired. Another had three labours, and in this case there was recurrence, requiring another operation. Thus prolapse sufficient to cause inconvenience had only returned in one out of 24 cases. The speaker was therefore of opinion that the addition to these vaginal operations of any abdominal intervention was unnecessary and undesirable, increasing the risk and discomfort to which the patient was exposed. He especially deprecated the use of abdominal measures not in addition to but instead of vaginal surgery.

Dr. F. H. LACEY said that the patients were mostly working women who had to return to work in cotton mills and other laborious work very soon after operation. He had written to 750 patients and received 521 replies, and 455 (87 per cent.) replied to the question, "Did the womb keep up well now?" with the answer "Yes." Of those who said "No" he had examined 29: 17 of these had some prolapse or other discoverable abnormality; one only had proclitidia, and she was aged 75 and had chronic bronchitis. Another had chronic bronchitis and asthma, while another had had to return to the cotton mill immediately after operation. Two others had had labours within one year after; 2 had elongated cervixes, and the remaining 10 had other conditions which had nothing to do with the previous operation—for instance, cystitis and senile vaginitis. The remaining 12 did not feel right, but they showed no anatomical abnormality.

The following table shows the relation of age to success and the percentage of successful cases grouped in decades:

Under 20 (1 case)	100 per cent.
21 to 30 (75 cases)	87 "
31 to 40 (200 cases)	89 "
41 to 50 (108 cases)	95 "
51 to 60 (47 cases)	83 "
61 to 70 (21 cases)	87 "
75 (1 case)	100 "

Taking those of reproductive age, he found that 330 successful cases had 67 children after the operation; 19 improved cases had 6 children; and 33 failures had 16 children. For the 67 children forceps were used in 32 per cent. of cases; for the 6 children forceps were used in 80 per cent. of cases; and for the 16 children forceps were used in 62 per cent. of cases; so that both failures and improved cases showed a higher ratio of labours, and these labours amongst the improved and failures showed a higher ratio of instrumental deliveries. This was what would be expected, and it was obvious that a colporrhaphy or any other operation could scarcely be expected to stand the strain of parturition better than the normal and natural pelvic floor. Dr. Lacey had only seen one death after vaginal operation, and that from pulmonary embolism. He considered abdominal operations unnecessary in the vast majority of cases, but admitted that rarely the abdominal route might be necessary in addition—for instance, in cases of congenital prolapse, or where certain complications existed, such as adhesion in a retroverted uterus. In St. Mary's Hospital no prolonged preparation of the patient was used; only one vaginal douche was given before coming on the table; the vagina was then cleansed with cresol, followed by perchloride, iodine being applied externally. No vaginal douching was used after operation, the parts simply being kept as dry and clean as possible.

Dr. A. DONALD, as a further introduction to the discussion, gave a short account of the history and early technique of colporrhaphy in Manchester. He believed that the operation had been more frequently done in that city than in any other city in this country, and as the oldest member of the present staff of St. Mary's Hospital he was able to speak of the earlier days of the operation. When he was a resident during the years 1834-87 it seemed to him that operative treatment on lines similar to those employed in the radical cure of hernia might be successful, although there was little encouragement in the literature of the subject. It was said that failure always resulted, and the standard textbook indicated that three methods of treatment might be tried: (1) Pessaries in mild cases; (2) a plastic operation on the vagina and perineum to enable the patient to wear a ring pessary in medium cases; and (3) an operation which was meant to

cause a union of the anterior to the posterior vaginal wall in advanced cases. In 1833, as surgeon to the hospital, he put his theory into practice, and in that year operated on six cases, in three of which comparatively full notes of the operation were taken.

The technique then employed was, with certain modifications, similar to his present methods. The cervix was amputated in cases where it was hypertrophied. The vaginal mucous membrane was divided transversely where it was inserted into the cervix in front, and stripped up off the cervix. The cervix was then divided into two lips, anterior and posterior, and a wedge was excised from each lip, care being taken to preserve a strip of the mucous membrane of the cervical canal of each lip, which was brought into apposition with the corresponding vaginal mucous membrane. On the anterior vaginal wall a diamond-shaped flap was dissected off, the whole thickness of the vaginal mucous membrane being removed. The raw surface was then brought together with a continuous catgut suture in the deep tissues, and this was covered in and buried when the lateral edges of the cut mucous membrane were stitched in the middle line. On the posterior wall a triangle was mapped out, with the apex close to the cervix and the base at the vaginal outlet. The sides of the triangle diverged, so that at the base they reached the middle of the labium minus of each side. The posterior colporrhaphy was done in stages from above downwards, the triangular flap being separated from its apex for about an inch, and then the sides brought together before the incisions were carried lower down. The deeper tissues were brought together by a continuous catgut suture, which was buried by the stitches uniting the mucous membrane. The healing was not so good in these days, because the catgut was not so reliable and came away early, and in most of the cases there was still a tendency to prolapse; but as a rule they satisfied the condition laid down in the textbooks, and enabled a ring to be retained.

In 1891 he operated on two cases of very bad proclitidia. In both the vagina was completely everted and a large ulcerated mass protruded from the vagina which could not be reduced until after the patient had been in bed for two weeks in one case and for three weeks in the other. In both these cases the operation was completely successful and the prolapse did not return. These cases finally established his belief in colporrhaphy as a curative operation. The number of colporrhaphy operations at St. Mary's Hospital had been used, and the late Dr. Walls, Dr. Dr. Fletcher Shaw had all given faith in the operation as a curative measure.

Dr. HERBERT SPENCER was fairly satisfied with vaginal operations and agreed that the abdominal method was unnecessary. He thought that in some cases of severe proclitidia no operation would be certain to cure, but that sometimes the best method might be the removal of the uterus *per vaginam* and packing of the tissues with gauze. He had performed colporrhaphy in 1887. He did not use catgut as he considered it might cause sepsis and tetanus, but instead used buried silk or silkworm-gut passed with a sewing needle.

Dr. T. G. STEVENS considered that, prior to 1913, London was far behind the Manchester school in the treatment of prolapse. He was convinced that the method described by Dr. Fothergill and Professor Donald was the best, that any case of proclitidia, however bad, could be cured by it, and that if failure occurred it was due to the patient getting up too soon or, more rarely, to a subsequent labour. He considered the operation could not be properly done unless catgut was used. There must in every such operation be some risk of sepsis, for the field was not an aseptic one. He preferred raw to chloricized catgut, as in the latter the surface was likely to be hardened and organisms remained intact in the middle, giving rise to sepsis and secondary haemorrhage. For moderate cases of prolapse as extensive an operation was necessary as in the severe cases, and the more severe the proclitidia the easier was the operation. He considered that abdominal operations played no part in the treatment of prolapse, but in a small percentage of cases—for instance, persistent retroflexion, leading to sacral pain—he had had resort to a Gilliam operation. This, however, had nothing to do with the treatment of prolapse.

Dr. A. E. GILES complimented Dr. Lacey upon the amount of work he had carried out in tracing the after-

OPERATIVE TREATMENT OF GENITAL PROLAPSE.

[THE BRITISH
MEDICAL JOURNAL]

histories of such a large number of cases. He considered that anatomical cure was the only real criterion of success in the operative treatment of genital prolapse. It was not enough to trust to the patient's report that she felt well; examination might reveal a certain degree of recurrence. He had found the vaginal plastic operation satisfactory in about 96 per cent. of cases. He did not find it necessary to amputate the cervix; if the uterus were put into proper position the hyperplasia of the cervix, which was due to the procidentia, tended to disappear. He protested against the wholesale amputation of the cervix except in hyperplasia of the vaginal portion in nulliparae, and claimed that as good results could be obtained by ventrofixation by proper methods, combined in certain cases with the vaginal operation.

Dr. J. E. GEMMELL (Liverpool) favoured the combined abdominal and vaginal methods, and described a method of ventrofixation used by him in which the utero-vesical pouch was obliterated. He had operated upon 480 cases at the Women's Hospital, and had traced the end-results in 192. The answers in all cases were satisfactory. He had done colporrhaphy alone in 40, interposition in 27, and a vaginal plastic operation combined with ventrofixation by his own method in 125. In advanced age he preferred interposition when the uterus was atrophied and there was complete prolapse of the vaginal walls. Especially in young women of child-bearing age he favoured the combined method—the vaginal operation combined with ventrofixation—as there was need of less removal of vaginal tissue, there were better results in parturition, and by his method a new fibro-muscular support was formed for the uterus inside the abdomen.

Dr. WALTER SWAYNE (Bristol) considered that details of technique mattered little; the important thing was that certain anatomical requirements should be fulfilled. Abdominal operation was incorrect anatomically; the damaged pelvic floor must be reconstructed on anatomical principles. He used buried catgut and did no abdominal operation unless there was some such condition present as retroflexion, or diseased ovaries or tubes. Where extensive plastic operations were carried out on women of child-bearing age they should be warned that subsequent labour might destroy the effects of a successful operation.

Dr. C. D. LOCHRANE (Derby) said that the ideal operation for prolapse should meet four requirements: (1) It should restore the parts to normal or as near that as possible; (2) it should be applicable to all ages; (3) it should not interfere with future pregnancy or labour; and (4) it should be the simplest, least dangerous, and least expensive possible. He had come to the conclusion that the vagino-plastic operation gave the best results, and he had during the last six years given up all other types of operation. He emphasized the importance of a careful preliminary examination to determine the sites of injury. He liked to get cases into a hospital three days before operation for vaginal cleansing. A light vaginal pack, soaked in 1 in 1,000 flavine, in saline, was left in overnight, on the night before operation. On the table the vagina, vulva, and perineum were swabbed with flavine (1 in 1,000) and picric acid (2 per cent.) in methylated spirit. He considered a good anterior colporrhaphy of the type described by Fothergill the most essential point. In cases with marked cystocoele the bladder should be separated and pushed up before closing the wound. He had found a light application of bipp to the wound in these cases useful in preventing cellulitis. He used no buried sutures, but secured a broad approximation of the levatores ani with figure 8 silkworm-gut sutures, then closing the wound from above downwards in the usual way with the shortest catgut sutures inserted deeply, and including in their deeper parts the already approximated borders of the levatores ani. The silkworm-gut was removed on the fifteenth day.

Professor H. BRIGGS thought it was possible to become obsessed with particular methods. It was only important to work along anatomical lines. He used catgut in all cases and thought that Dr. Stevens's secondary haemorrhage might be due to excessive trauma. He protested against elaborate descriptions of special methods and against a tendency to make exaggerated statements.

Dr. WALTER GRIFFITH thought that abdominal operation might be necessary in certain conditions, as where a retroflexed uterus was complicated by adhesions or by prolapsed inflamed ovaries.

Dr. R. H. PARANORE (Rugby) was surprised that there was no reference to myorrhaphy of the levator ani during the discussion. Was that now considered of little value? He considered that if its edges were brought together the union did not persist, and if it did that would be an abnormal condition.

Professor GAMMELTOFT (Copenhagen) did not consider abdominal operation necessary. He used catgut, and carried out a myorrhaphy of the levator ani in perineorrhaphy.

Dr. J. S. FAIRBAIRN said it was sometimes difficult to judge of the amount of narrowing of the vagina that would follow plastic operations. He only removed the cervix in cases where there was extreme elongation, chiefly owing to the danger of secondary haemorrhage. The position of the uterus varied widely within normal limits, and he considered a symptomatic cure far more important than an anatomical one.

Mr. FURNEAUX JORDAN had for many years done a combined operation, but gradually had come to rely entirely upon the method described by Fothergill. He found he got better results and patients were more comfortable when the cervix was amputated. He believed a plastic operation to be sufficient.

Dr. MILES PHILLIPS thought that no one set procedure would cure every case. Plastic operation alone cured a large percentage of his cases, but in about 4 or 5 per cent., chiefly women over 60 with atrophy of the uterus, he removed the uterus from the vagina, and in addition did an extensive plastic operation, excising a large portion of the pouch of Douglas and stitching the broad ligaments underneath the bladder. He considered abdominal operation unnecessary in prolapse, but a few cases returned with retroversion, and if such failure to get the uterus into an anteverted position could be anticipated, it might be better to do an abdominal operation and complete the cure at the same time.

Dr. T. W. EDEN thought that no set procedure suited every case. He had found the method of vaginal hysterectomy described by Dr. Miles Phillips useful in some cases. Also in congenital prolapse in young women where ligaments and supports were lax and the round ligaments poorly developed it was useful to duplicate the utero-sacral ligaments, obliterating the pouch of Douglas, anteverting the uterus, and at the same time shortening the round ligaments which were lax and long. He emphasized the importance of anteverting the uterus, and considered that if left retroverted recurrence was almost bound to take place.

Dr. W. H. C. NEWNHAM had almost entirely given up the abdominal method and got uniformly satisfactory results by plastic procedures.

Dr. FOTHERGILL, in reply, said that he had very little trouble with secondary haemorrhage, and when it occurred it could be easily checked by packing. Cases complicated by cancer, fibroids, or prolapsed ovaries were not being talked of; the discussion was on genital prolapse. Of course, he operated on such cases by the abdomen. He did not do the interposition operation. Deaths had followed it, and one should not risk killing patients in order to cure prolapse. He did not like vaginal hysterectomy in prolapse, and in his experience some of the worst cases of prolapse had occurred after the uterus was removed. Congenital prolapse might cause difficulty, but in his hands they had been cured by plastic methods.

Dr. DONALD agreed that secondary haemorrhage was one of the drawbacks. He did not pack for it, as the packing stretched the parts too much and spoiled the operation. He considered a symptomatic cure more important than anatomical. The addition of an abdominal operation to a plastic greatly increased the risk, especially in old women, and vaginal hysterectomy often resulted in ultimately increasing the prolapse. He did not trouble about getting the uterus into a position of anteversion.

The afternoon session was devoted to the demonstration of specimens and to short communications. Dr. CLIFFORD WHITE exhibited two specimens showing an unusual condition of sutures after Caesarean section. Dr. EWEN MACLEAY demonstrated a specimen showing a degree of absorption of silk sutures after Caesarean section; hysterectomy had to be done for fibroid five months afterwards, and several silk sutures were found unabsorbed, while microscopically distinct phagocytosis was seen in the uterine wall around

the suture area. The demonstration of these three specimens led to a brisk discussion of the relative merits of silk and catgut in Caesarean section, in which Drs. HERBERT SPENCER, EARDLEY HOLLAND, MILES PHILLIPS, and COMYNS BREKLEY took part.

Dr. EVEN MACLEAN demonstrated another specimen showing combined fibromyoma and carcinoma of the uterus. He referred to the rarity of the combination, only 0.4 per cent. in 500 cases in which he had removed the uterus for fibroid. Dr. HERBERT SPENCER and Dr. EMMETT both considered that Dr. Maclean's figures showed an unusually low cancer incidence in the fibroid-containing uterus, and the former thought it might have something to do with the district in which Dr. Maclean practised. He had found 6 out of 200 had unrecognized cancer of the uterus, and there were many more cases in which it was recognized.

Dr. HAROLD CHAPPEL showed a specimen illustrating "full time ovarian pregnancy." The foetus had been retained three and a half months after full time; no ovarian tissue had yet been demonstrated in the wall of the sac, but the tube was stretched over it and the ovary of that side was not found. Several speakers discussed the probability of its being a tubo-ovarian pregnancy, and eventually it was decided to have the matter brought up again at the Royal Society of Medicine after completion of the pathological examination.

Dr. G. L. STRACHAN (Cardiff) showed a specimen of an early ovum which he thought to be of not more than twelve to fourteen days development. In an oblique section through the cephalic extremity the neural matter could be seen just beginning to be differentiated into grey and white.

Dr. F. J. BROWSE (Edinburgh) read a communication entitled "Some points in the pathology of syphilis of the newborn, based upon a study of 35 cases." The author pointed out the necessity, before arriving at a *post-mortem* diagnosis of syphilis, of taking into account all the available evidence—that derived from the clinical history of the parents, the Wassermann test, the placenta, and a complete naked-eye and microscopic examination of the foetus and its internal organs, especially the lungs, liver, spleen, thyroid, thymus, and pancreas. Lantern slides were shown illustrating the histological changes in these organs. The unreliability of naked-eye appearances was discussed, and it was pointed out that the only evidence obtainable of the presence of syphilis might be the histological changes in the organs. The paper was discussed by Dr. EARDLEY HOLLAND, Dr. SWAYNE, and Dr. STRACHAN.

Mr. GORDON LUCKER read a paper entitled "Notes on 250 cases of ectopic gestation." Dr. LAPHORSE SMITH, Dr. PERSLOW, Dr. EARDLEY HOLLAND, Dr. GILES, Dr. WILLIAMSON, and Mr. CARLTON OLDFIELD taking part in the subsequent discussion.

Dr. WALTER SWAYNE (Bristol) then read a paper on a case of chorion-epithelioma in a nullipara; there had been three months' amenorrhoea, followed by irregular haemorrhages; the patient was aged 50, unmarried, and a virgin. The primary growth was in the uterus, with secondary growths in the mesentery and lymph glands.

Dr. STEVENS led the discussion that followed, and doubt was expressed by several speakers as to whether the case was really one of chorion-epithelioma, the microscopic section on view showing no evidence of the presence of syncytium.

In the evening an enjoyable dinner was held, the chair being occupied by Mr. CHRISTOPHER MARTIN. The toast list included, in addition to "The King," "The Visiting Societies," proposed by the CHAIRMAN and responded to by Dr. MILES PHILLIPS, and "The Midland Obstetrical Society," proposed by Professor H. BRIGGS and responded to by Sir EDWARD MALINS. The morning of Saturday, June 4th, was spent in witnessing operations at the different hospitals of the city, and arrangements were made for golf and excursions in the afternoon.

Thus has come and gone the first British Congress of Obstetrics and Gynaecology—one that was voted by all who were present to have been a great success from both the scientific and the social points of view. This was largely due to the excellence of the arrangements made and the hospitality shown by the Midland Obstetrical and Gynaecological Society, the secretary of which, Mr. Beckwith Whitehouse, upon whose shoulders most of the work naturally fell, is to be heartily congratulated.

PATHOLOGICAL CHANGES IN BREAST EPITHELIUM.

At a meeting of the West London Medico-Chirurgical Society held at the West London Hospital on June 3rd, with the President, Dr. F. J. MCCANN, in the chair, a paper was read by Sir G. LENTHAL CHEATLE on some pathological changes in the epithelium of the breast. He said that he would confine his remarks to two main points: (1) to indicate the surgical importance of the ampullae of the breast ducts; and (2) to draw attention to three separate conditions in the breast, all of which had been described to him as "parenchymatous mastitis" by different observers, but of which, in his opinion, only one could be thus justly described.

1. Whole sections of two breasts were shown; in one the ampullae of two ducts contained papillomatous tumours, while in the other one duct ampulla contained an even larger papillomatous tumour. All the ampullae containing the tumours were distended by the growths. Whole sections of a third breast were next shown in which the ampullae of two ducts were distended by cancer. The cancer was undergoing colloid degeneration at the time of excision of the breast. It was pointed out that these sections demonstrated simple growths in one case and malignant in the remaining two, all occurring in the ampullae of the ducts. Sections were then shown of mammary ducts ending in the nipple surface. There was nothing to guard against the entrance of irritating agents except the contraction of the dense musculature surrounding the ducts. Irritating agents might collect in the ampullae and there act undisturbed upon the epithelium lining the duct dilatations.

2. Sir Lenthal Cheate first dealt with only one of the three conditions he had mentioned which in his opinion justly deserved the term "parenchymatous mastitis." A longitudinal section of an affected duct was shown which exhibited in its surface a localized patch of swollen epithelium. Among the epithelial cells were lymphocytes, a few polymuclear leucocytes, and also newly divided connective tissue cells. There was no ulceration in this duct. Another duct from another breast was also shown in longitudinal section. It contained a patch in which the same process seen in the previous section was occurring, but it had been more intense in character and the surface of the duct had been ulcerated. This condition must be parenchymatous mastitis. It occurred in breasts in which some chronic disturbances were in progress, such as in advanced cancer. In many cases the ducts only were affected, but in some the ducts and a few of the acini with which they communicated were also affected. It could not be very uncommon to find all the acini involved and some of their ducts sharing in the inflammatory changes. His next point was the condition he was anxious to remove from the nomenclature of parenchymatous mastitis, and he showed many sections of breasts which demonstrated his point. He preferred to call it a "diffuse benign neoplastic state." In many cases the ducts only might be affected; in other parts both the ducts and acini were undergoing a similar change. The changes were these: there was a proliferation of epithelium lining the ducts and perhaps some of the acini in connexion with them. The cells which resulted from this proliferation appeared as desquamated cells and collected in great numbers and distended the ducts. This neoplastic change the lecturer considered a common cause of cysts in the breast. There was practically no inflammatory change seen in this condition. Where in some cases collections of lymphocytes could be demonstrated these collections were so far apart and small that it appeared impossible to conceive that they could be causing the neoplastic change. These changes he regarded as secondary. Papillomata were not present in this condition. The third condition described to him as being a form of parenchymatous mastitis he regarded as a state of cancer. Sections were shown in which the ducts, distended with epithelial cells, were being ulcerated by infiltration into surrounding parts by these cells. The subjects from whom were prepared some of the specimens shown of this type of breast had died of cancer.

The President congratulated the lecturer on the excellent series of whole breast sections he had shown. He emphasized the close connexion that existed between papillomatous changes and cancer, referring particularly to these conditions in the uterus.

REVIEWS.

Mr. McADAM ECCLES recalled that the late Mr. Keetley, the founder of the society, had many years ago expressed the belief that cancer of the breast was always due to infection through the ducts. Mr. Eccles was certain there was a close connexion between papillomata and infection. This was well seen in the case of the bladder. He regarded also many of the cysts of the epididymis as of infective origin. In doubtful breast conditions in women over 50 he thought it safer to advise complete removal of the organ, but not necessarily of the muscles and lymphatic tracts.

Dr. RICKARD LLOYD referred to cases in his practice in which cancer had been proved in patients presenting scanty evidence of the true condition on clinical grounds. He also mentioned cases in which life had been prolonged many years after operation at an early stage for cancer.

Dr. KNYVETT GORDON spoke as a pathologist of the difficulty in many cases in deciding what the true condition was from an examination of only a small portion of the breast. The whole breast section was undoubtedly the best method, but was often impossible. He thought that when intra-acinar proliferation was marked the whole breast should be removed, and where the basement membrane was ruptured the muscles and lymphatic tracts could be removed as well. He did not agree that duct apillomata were necessarily benign.

SURGERY OF NASAL DEFORMITIES.

At a meeting of the Medico-Chirurgical Society of Edinburgh on June 1st, Sir JAMES B. HODSDON presiding, Dr. DOUGLAS GUTHRIE read a paper on the surgery of nasal deformities. He emphasized the importance of immediate replacement of the injured and deformed parts, and of not forgetting the possibility of septal deflection. Of the common types of deformity, he took first that of lateral deformity or twisted nose; with this there usually was also some deflection of the septum, with partial or complete blockage of the nostrils. The treatment was a submucous resection of the septum, with division of sunken bridge or saddle nose, produced by violence, by an extensive resection of this type of deformity by syphilitic disease. Cases of successful treatment of this type of deformity by cartilage graft were described. The graft was obtained from the seventh costal cartilage, and the advantages of such a graft were that it was a natural tissue, that it could be readily shaped to fill the gap, and that it persisted unchanged. The results were least satisfactory in syphilitic disease. The third type was that of nostril deformity, of which three examples were given—one a deflection of the lower end of the septum, one a stenosed nostril produced by redundant tissue of the graft of a previous plastic operation, and the other a case of alar collapse.

Mr. D. M. GREIG advocated the use of paraffin in preference to a graft operation in cases of sunken bridge where the condition was congenital and without scarring; the operation was easy to perform, could be carried out in the out-patient room, and had given him excellent results. Dr. GUTHRIE, in reply, said that his only experience of the paraffin had been in removing it where it had failed; it wandered into distant tissues, even into the eyelids, where it gave much trouble.

Treatment of Fractures of the Upper Extremity.

Mr. J. W. DOWDEN discussed the principles of the treatment of fractures of the upper limbs. The classical use of splints and prolonged fixation of the parts might give a good result, but much time was wasted. Lucas-Championnière had revolutionized the older treatment by his advocacy of early massage and passive movement. The speaker carried the new doctrine a step further, and advocated early active movement. The principles of his treatment in fractures of the upper extremity were as follows: A sling supported the forearm, the angle at the elbow was altered several times a day, and the range was steadily and painlessly increased. Active movements of all joints and muscles were frequently carried out during the day, increasing the range steadily, and following on the heels of pain. Pain was absolutely the indicator of how far active movement might be carried out by the method was so simple that it could be carried out by young children as well as by adults. Cases of fracture of

the clavicle, of the scapula, humerus, elbow, forearm, and wrist were described, and the injuries, with the functional and anatomical results, were illustrated by x-ray photographs. Certain regions offered special difficulties, notably the elbow and wrist, but even there the results were superior to those of the conventional methods. He had used the method also in severe compound fractures due to war injuries, where its superiority was equally marked; he had not had a case of non-union in compound fracture of the humerus treated in this way.

Mr. C. W. CATHCART said that the results given by this method were well founded, and were an advance in the treatment of fractures; they broke through the dictum that a good functional result could not be obtained without a good anatomical result. But he was doubtful if the method could be applied to fractures of the lower extremity. Mr. D. M. GREIG expressed general agreement, but said that in fracture of the olecranon and in fracture of the humerus in babies it was not suitable. Mr. PIRIE WATSON said he had adopted the method in surgical out-patient work, modifying it by the use of splints for the first few days. Dr. C. SOMERVILLE reported a case of fracture of the ulna in a chauffeur treated by this method, where the man was using the arm again at his work fourteen days after the injury.

Keratoderma Blennorrhagica.

Dr. DAVID LEES reported two cases of this rare condition, showing casts and photographs of the skin lesions. The lesions, horny heaped-up growths on the skin, with parchment-like areas between, were commonest on the soles of the feet, but occurred also on the legs, scrotum, back and abdomen. Forty-seven cases in all had been recorded. The condition was a manifestation of gonococcal toxæmia, and also urethritis; only once had gonococci been present, and also urethritis. His first case was a man aged 22, who had unusually extensive skin lesions, with negative Wassermann and positive gonococcal tests. His treatment was as follows: Local application of a solution of arsenic and ipecacuanha in rectified spirit; large doses of gonococcal vaccine (twenty thousand million); and liminary desensitization; and injections of novarsenobillon. The condition was cured in six weeks and had not recurred. In the second case, a woman aged 63, with the characteristic lesions on the soles and legs, bacteriological and serological proof of gonococcal infection was lacking, and the Wassermann test was also negative. A similar course of treatment was given, and again the horny growths had entirely disappeared. In three months they relapsed, but again cleared up after a second course of novarsenobillon.

Reviews.

DEFICIENCY DISEASE.

McCARRISON'S *Studies in Deficiency Disease*¹ is a notable book. It is one which demands careful study and full consideration by all medical men. It comes at the right time when our knowledge of the vitamins is crystallizing, and when the new idea that disease is not necessarily due to the activity of a positive agent, but to the absence of indispensable ingredients of diet, is sinking in. As of indispensable ingredients, most attention is directed to those was to be expected, most attention is directed to those conditions caused by absence of the antineuritic vitamin, for it was in relation to that material that the author made his name by his published researches. But quite an adequate account is given of the effects due to the withholding of other vitamins, including the disease pellagra, which in all probability is not quite on all-fours with the other ailments, now labelled as Deficiency Diseases.

"Vitamins are as the spark which ignites the fuel mixture of a petrol-driven engine liberating its energy. The spark is of no use without the fuel, nor the fuel without the spark—may more, the efficacy of the spark is dependent in great measure on the composition of the fuel mixture."

These illuminating sentences (p. 210) really put the whole problem in a nutshell. Absence of food leads to

¹ *Studies in Deficiency Disease*. By Robert McCarrison, M.D., D.Sc., Hon. LL.D., Belfast. London: Henry Frowde, and Hodder and Stoughton. 1921. (Sup. roy. 8vo, pp. 286; 82 figures. 30s. net.)

starvation; absence of the vitamins renders the food useless, and so also leads to inanition. Inanition or starvation is the essence of all deficiency diseases; the malnutrition so produced renders the tissues an easy prey to infectious agents, so that conditions due secondarily to the latter may cause further symptoms to be superimposed on those due to failure of the food supply. It was first by Dr. McCarrison's work on the effect of avitaminosis, in which he examined the various organs and tissues of the body, that he proved this thesis up to the hilt. The abundant histological features of the effects in these tissues will convince the observer of the similarity in the two cases, starvation and avitaminosis. The remarkable effect on the adrenal body, which hypertrophies, is a case in point. Endocrine insufficiency in other organs is another most important factor, and gastro-intestinal disturbances are pre-eminent. It is no doubt true that the absence of individual vitamins will produce different effects, and it is useful to be able to speak of the vitamins A, B, and C as being antiscorbutic, antineuritic, and antiscorbutic respectively; but underlying all, starvation is at the root of the matter.

A preliminary cursory perusal of the book makes one think the matter is presented in rather a muddled way. Chapters are given which deal more especially with rickets, scurvy, etc. (each, by the way, provided with a useful summary at the end), but, speaking generally, there is no hard-and-fast line drawn between them. When, however, the book is studied carefully, one sees that there is sanity in the author's method. No hard-and-fast line can be drawn because no such line exists; a vitamin cannot be studied individually without consideration of the activities of its fellows. Take, for example, vitamin B so often spoken of as antineuritic, because neuritis is so prominent a symptom in beri-beri, where that vitamin is absent; neuritis is prominent, but it is not the only symptom; other symptoms and other effects are the result of general malnutrition.

The author does not simply describe the effect of his numerous and painstaking experiments on animal—(rats, guinea-pigs, monkeys, birds, etc.), the special value of his work lies in their direct and immediate application to man. His commendation of Hindhede's views in one of the earlier pages makes one think that Dr. McCarrison must be a vegetarian or has leanings in that direction. He certainly recognizes how animals are dependent on the plant world for their vitamin supply, but any suspicion of pure vegetarianism is at once dispelled when one reads the closing chapters, which deal more particularly with the practical applications of his work to human dieting. There we have profound and intimate knowledge of the human wants to be supplied, not only with adequate, but with properly balanced rations.

Before the discovery of the vitamins attention was in the main directed by dieticians to the quantity of the food supplied. The quantity is important, and enough must be given to supply the body with repairing materials and to form the source of the energy dissipated. The quantity of petrol in the tank puts a limit to the work a motor car can perform. But quantity is not the end-all; the sparking apparatus must be in order too. The quantity of vitamin necessary in a diet is infinitely small; its presence is indispensable, and comes under the head of quality rather than quantity. The whole attitude of dieticians accustomed in the past to speak in terms of calories, and little else, has altered. There are proteins and proteins, fats and fats, and so forth, and not the least important—perhaps the most important—qualitative factor is the presence of these accessory food materials about which we chemically know next to nothing.

It is customary, in dealing with the subject of diet, to suppose that in a mixed diet such as the well-to-do have at their command the risk of deficiency disease is minimal, for an item lacking in one article of food will be made up for in another. This probably is the fact, and so pity for the poor follows, because they have, *nolens volens*, to take a restricted diet both in amount and kind. At the same time it is not the poor only who suffer. Infantile scurvy, latent or declared, is an ever-present danger, and is as common in the children of the rich as of the poor, probably more common, so widespread is ignorance of the principles of dieting, and so great the affection of the public for fractionated, treated, widely advertised and expensive substitutes for natural foods. Without going into many details of cases where ill-balanced nutriment upsets health

one cannot refrain from alluding to the case of the unfortunate boy fully described on page 238 et seq. He was in a good social position, had happy and hygienic surroundings, and a dietary "varied enough and liberal enough," but yet did not thrive. On examining his food it was found that the variations had been rung on just the wrong things. His recovery when fed on a diet of the right sort was remarkable. The case which follows this—that of a lady—is equally instructive, but space forbids a fuller description. Those who read this review must obtain the book and inwardly digest it.

A moot point still unsettled is the part that diet plays in the etiology of rickets, and the condition of bad teeth so closely allied to it. No! Paton and his colleagues have seen reason to doubt whether vitamin deficiency is at the root of this malady, and their recently published results were too late to be noticed in the present book. One anticipates that a second edition will soon be called for, and then we shall look forward to what Dr. McCarrison has to say on this disputed question. Until then we must be content with congratulating the author on his first edition and with recommending our readers to study it for themselves.

W. D. HALLIBURTON.

VACCINE AND SERUM TREATMENT.

OF SERGEANT, RIBADEAU-DUMAS AND BARONNET'S *Traité de pathologie médicale et de thérapeutique appliquée*, which is to consist of 32 volumes, the tenth volume to appear is that numbered xxx, on bacteriotherapy, vaccinotherapy and ferrotherapy, with, as its second part, occupying 200 pages, an account of remedies in common use arranged according to their therapeutic action and not in alphabetical order, by H. Carron.

The first, and by far the most interesting, part deals with the modern methods of treatment derived from the science of bacteriology. It is written by Dr. Pierre Pruvost, who points out in the introduction that serums and vaccines exert both specific and non-specific effects, the latter being connected with changes in the colloidal equilibrium of the body fluids and the blood changes preceding shock and anaphylactic phenomena described by Vidal and his co-workers as the haemoclastic crisis. For practical purposes the various methods employed are divided into three categories: the first contains those forms of treatment which have a well-established position, such as antidiaphtherial, antitetanic, antityphoid, and antimeningococcal serums; the second a large number of vaccines and serums which, though often useful, are not constantly effective; and the third group consisting of those which, while of high scientific interest, have not yet been adopted in practice. In the section on bacterial therapy, or the use of living and harmless bacteria, with the object of exerting an antagonistic action on pathogenic organisms, the treatment with lactic acid bacilli is fully described, and reference is briefly made to pyocyanase.

The various vaccines are described in detail, with clear directions as to the contraindications to their use; the section on antityphoid inoculation occupies twenty pages, and deals with both its prophylactic and curative applications. The protection conveyed is regarded as lasting on an average for a period not exceeding two to three years, and the curative effect, of which quite a moderate estimate is made, is stated to be more satisfactory in early life.

The section on serum therapy deals first with saline injections, then gives an account of anaphylaxis and serum reactions, and finally supplies a detailed description of the various serums, those on antidiaphtherial and antimeningococcal serum being particularly full. In the special chapter on non-specific serum treatment the administration of horse serum in haemophilia receives full attention, and the difficult subject of injections of proteins is discussed. A well-illustrated chapter on blood transfusion and some general conclusions complete Dr. Pruvost's valuable and up-to-date contribution.

²*Traité de pathologie médicale et de thérapeutique appliquée*. Publié sous la direction de Emile Sergent, L. Ribadeau-Dumas et L. Baronnet. Tome xxx, Thérapeutique; tome ii, Bactériothérapie, vaccinothérapie, sérothérapie, formulaire de thérapeutique. Par Pierre Pruvost et H. Carron. Paris: A. Maloine et Fils. 1921. (Dern. 8vo, pp 523; 35 figures. 23 francs.)

AN AMERICAN TEXTBOOK OF GYNAECOLOGY.

ANY textbook of gynaecology which appears with the imprimatur of Dr. John G. Clark obtains thereby a good send-off, and is certain to receive more than passing attention from those to whom Dr. Clark's name stands for all that is soundest in American gynaecology. Dr. BROOK M. ANSPACH is, therefore, not only upon having such a book, but also upon his having made the book worthy of its sponsor. Founding on an accurate, full, and lucid description of the anatomy and physiology of the reproductive organs in woman, the author follows the usual procedure of discussing the causes in general of pelvic disease and the methods of investigating it. The examination of the urinary system is particularly fully dealt with, and includes catheterization of the ureters, pyelography, and the estimation of the renal function. In his description of the diseases and abnormalities of the different organs Dr. Anspach follows the topographical classification, and while we may regret the sacrifice of strict scientific perspective which this arrangement entails we cannot but admit that on the whole it makes the subject simpler to the student or practitioner who has not given special study to the subject; together they form the public for whom the book is designed. An attempt to redeem the sacrifice is made by devoting separate chapters to the special peculiarities of certain forms of infection, notably gonorrhoea, tuberculosis, and syphilis.

The last sections of the book are occupied with the description of therapeutic measures, operative and medicinal. Special sections of considerable value are devoted to the discussion of radium and x-ray therapy, and to the use of vaccines in gynaecology. The book is sumptuously illustrated by 526 figures, most of which are well designed and likely to prove helpful. At the end of each section is a short but carefully selected bibliography of the more important papers on the subject, culled from both the more classic sources and the most recent work. Dr. Clark in his introduction makes particular reference to this, and we agree that the author has exhibited great discrimination in his choice of references.

The general impression that the book has made upon us is that, without being encyclopaedic, it is full and complete, accurate, lucid, practical, and throughout written with the restraint that is the hall-mark of a well-balanced judgement. We congratulate Dr. Anspach accordingly. Not for a long time have we seen an American textbook so well calculated to become popular with students on this side of the Atlantic as well as in the land of its birth.

A YEOMANRY MEDICAL OFFICER.

THE titanic struggle on the Western Front to a large extent overshadowed the campaigns elsewhere, at any rate in popular interest, and this probably applies to the medical service equally with other branches. Captain TEICHMAN, by publishing his *Diary of a Yeomanry M.O.*,⁴ has rendered a distinct service to the medical records of the war, and his daily record of the doings of a regimental medical officer cannot fail to interest many whose experience was largely confined to the trenches of France. So rarely, except in the last phase, did open fighting occur in France, that the account of the Egyptian and Sinai episodes seems to refer rather to war as understood before 1914, when troops moved in the open, cavalry patrols were constantly engaged, and the enemy showed an enterprise, and yet a regard for the common usages of warfare, which was far removed from the ruthless bitterness of the Germans as exhibited in France.

Captain Teichman does not profess to give any critical description of the operations in the various fields, but in homely fashion jots down the doings of his own regiment, the Worcester Yeomanry, adding such explanations of the general movements as a regimental officer could get to know. He is modest about his own deeds, but it is possible to read between the lines and to recognize that he must have been a most excellent regimental M.O., not sparing himself in work, nor thinking of personal risk. That he was twice wounded is sufficient proof of this,

apart from the decorations which indicate what others thought of his work. It is impossible to estimate what it means to a regiment to have a medical officer who is always "up" with them, and the R.A.M.C., with many fine achievements to be proud of, may regard as its finest the fact that there was a constant flow of such men, who by their cheery optimism as well as their medical and surgical skill did so much to sustain the spirits of all ranks. The value of a medical service depends as much on this as on its technical abilities. Regimental work was often a matter of personal self-sacrifice to a keen professional man, for his opportunities for more than elementary first aid or hasty symptomatic treatment were scanty, and it was only the recognition of the opportunities for the wider scope of service that reconciled the doctor to his very limited professional field.

Of special interest is the description of the difficulties of arranging transport for the wounded, and how they were overcome. Dhoolies, traverses, sand carts, and mule and camel litters were all employed, and the Ford ambulances were of great use in Sinai. Little reference is made, however, to the bugbear of all work in France—the ever-present sepsis,—and it would seem that this was a problem of comparatively small importance. Tropical diseases, particularly malaria, gave rise to much more anxiety. It is tempting to follow the author over the various fronts, and to quote some of the incidents he records. The despatching of a venomous snake by D.R.L.S. to the A.D.M.S., who desired specimens for the preparation of antivenene, is a case in point, and the urgent "stop" wire from that officer, who was probably inundated with infuriated and highly venomous reptiles, recalls instances which occurred elsewhere of an order producing embarrassing results.

Until he was drafted to Italy, just before the end, Captain Teichman was fortunate, probably exceptionally so, in returning to his own unit each time after he was a casualty, and therefore the *Diary* is a regimental as well as a personal record; it will be perused by the Yeomanry with as much interest as by its medical readers, who should be numerous.

NOTES ON BOOKS.

PROFESSOR ARTHUR THOMSON'S well known *Outlines of Zoology*⁵ has now reached a seventh edition. It has undergone revision in order to bring it up to date, and by some additions the number of illustrations has been raised to 437. The book is perhaps of more use to the student of general zoology than to the medical student, since it contains much that is not required by the latter; yet every intelligent student will find interest in such subjects as geographical doctrine of descent, which make the dry bones of morphology of more living interest. Moreover, it is just these very subjects in which Professor Thomson is a past master of the art of exposition. The new edition, which is the seventh, contains a bibliography of the more important textbooks and books on natural history, together with a number of representative test questions for students, which will be of considerable value to the "home student."

*The Canadian Mother's Book*⁶ is a sensible little book written in simple—and sometimes rather ecstatic—language, for the expectant and nursing mother; it is issued by the Child Welfare Division of the Canadian Department of Health. It emphasizes, more than most books of this nature do, the fact that practically every mother, if properly instructed, ought to be able to nurse her baby. "We are all responsible," it says, "for the folly of artificial feeding."

Colonel G. T. BIRDWOOD'S *Clinical Methods for Students in Tropical Medicine*,⁷ of which the third edition has recently been published, is a book which does not waste a word, but in a very practical and pointed manner carries out what it sets out to do. In the new edition Colonel Harvey has rewritten the chapter on the Wassermann

³ *Gynecology*. By Brooke M. Anspach. University of Pennsylvania Press. London: J. B. Lippincott. 1921. 42s. net.

⁵ *Gynecology*. By John G. Clark. 1920. pp. 775; 526

⁵ *Outlines of Zoology*. By A. J. Thomson, M.A., LL.D. Seventh edition, revised. Edinburgh, Glasgow, and London: H. K. Lewis, and Hodder and Stoughton, 1921. (Cr 8vo, pp. 840; 437 illustrations. 12s. 6d. net.)

⁶ *The Canadian Mother's Book*. Ottawa: The Deputy Minister, Department of Health, 1921.

⁷ *Clinical Methods for Students in Tropical Medicine*. By G. T. Birdwood, M.A., M.D., D.P.H., Lieut.-Colonel I.M.S.; with foreword by Sir J. Roberts, Kt., C.I.E. Calcutta and Simla: Thacker, Spink, and Co.; London: W. Thacker and Co. 1920. (Fcap. 8vo, pp. 221. Rs. 7.8.)

reaction, and Major Megan has written a chapter on the examination of faeces. Colonel Birdwood has contributed new chapters on the recent treatment of leprosy, the management of hookworm disease, and the identification of poisonous snakes. The book is very usefully interleaved, but the index might well have been improved. It is, however, certainly a volume which every student of tropical medicine should possess.

In *The Octocentenary of Reading Abbey* Dr. JAMIESON B. HURRY* has given an interesting sketch of the Noble and Royal Monastery of Reading, founded on June 18th, 1121, by Henry I, who was buried there after his death, on December 1st, 1135, from "a surfeit of lamprey," to which he appears to have been both partial and sensitive, for as this fish always made him dyspeptic it had been banned by his physicians. In 1164 Thomas à Becket dedicated the abbey church to the worship of God, and twenty-one years later Heraclius, Patriarch of Jerusalem, knelt here before Henry II and unsuccessfully implored him to save Jerusalem from capture by Saladin. It was in Reading that, about 1240, the unknown monk composed "Summe is icoming in," one of the earliest examples of English secular music. King Henry VIII dissolved the abbey, and in 1539 the last abbot, Hugh Cook, Earlsgodown, after a sham trial for treason, was executed before the gateway of his own stately abbey. Reading is, indeed, fortunate in its historian who has produced this attractively written and finely illustrated volume.

**The Octocentenary of Reading Abbey (1121-1921)*. By Jamieson B. Hurry, M.A., M.D. London: Elliot Stock, 1921 (Imp. 8vo, pp 101; 10 plates. 10s. 6d. net)

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on May 10th, twenty-one cases were considered, and £303 voted. The following is a summary of the cases relieved:

Daughter, aged 73, of M.R.C.S. Eng. who died in 1921. Owing to a limited income and having to help towards the expenses of a bed-ridden brother in a nursing home, applicant has asked the Fund to help her to supplement her £10 annuity of £50 and the £1 she was paid for making fancy lace and putting little water colour sketches. Since the war she has had to pawn family things and pay a heavy rate of interest. Her sister applied to the Fund and the Committee made her a grant of £10. Voted £10.

Widow, aged 25, of M.R.C.S. who died of typhus while working on a Red Cross train in 1920. Applicant managed to escape from Russia with her little son and arrived in England without means and is at present being supported by friends. She is very anxious to be self-supporting and to this end has applied to the Fund for help and to advise in placing her son in a school. Voted £10.

Widow, aged 55, of L.P.S. who was acting as surgeon on board when torpedoed and all were lost. Applicant receives a pension from the War Risk Association of £5 6s 8d a month. Rent 11s a week. Her youngest son, who is in the merchant service, is now out of work, and applicant finds it difficult to support two on her small pension. Voted £10 in two instalments.

Widow, aged 29, of L.R.C.S.I. and L.R.C.P. Edin. who died in 1918. Her sole income consists of £2 annuity derived from life insurance. Applicant asks for help to supplement this annuity as her rent is £10, and her board costs 15s. per week. Voted £13 in twelve instalments and also a special grant of 4s.

Widow, aged 55, of L.S.A. who died in 1921. Owing to illness applicant's late husband was helped by the Fund. His widow asks for help as she has no settled income. She receives from friends about £25 per annum, and 7s. 6d. a week by letting rooms, her rent is 17s. 6d. a week. Voted £10 in two instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

MESSRS. BAILLIÈRE, TINDALL AND COX'S current catalogue gives a list of recently published new books and new editions, with descriptive notes. For the convenience of those who wish to order direct from the publishers the weight of each book is given and the postal rates.

The thirty-fifth annual meeting of the American Orthopaedic Association was held at Boston, Mass., from June 2nd to 6th. In addition to many contributions made by the leading American orthopaedic surgeons were papers on "The manipulation of stiff joints" and on "Surgical aspects of milk-borne tuberculosis," by Sir Robert Jones, and another on "Peripheral nerve injuries," by Mr. Harry Platt. Sir Robert Jones also gave clinical and operative demonstrations.

THE VOLUNTARY HOSPITALS COMMITTEE.

We gave last week, at p. 870, a preliminary account of the report of the Voluntary Hospitals Committee, together with a summary of those recommendations which, if adopted, would require legislative or executive action. The Committee was appointed by the Minister of Health on January 25th, 1921, with Viscount Cave as chairman, "to consider the present financial position of voluntary hospitals and to make recommendations as to any action which should be taken to assist them." In an interim report, described in our issue of March 26th, p. 463, the Committee urged that contributions to voluntary hospitals might reasonably be made out of the available surplus funds of approved societies.

The final report, published on June 9th, is discussed elsewhere in a leading article. We propose to give here a more detailed account of certain matters of general interest, quoting from those sections which specially concern the medical profession.

In order to expedite its report, the Committee limited the evidence to witnesses representing groups of hospitals, or hospitals which might be taken as typical of a number of similar institutions in various parts of the country. Some of the Scottish evidence was heard on behalf of his colleagues by Lord Linlithgow in Edinburgh, and some of it by the Committee in London; the Irish hospitals were not included in the reference. The oral evidence was supplemented by a questionnaire issued to all hospitals outside the London area. The Committee also took evidence from representatives of the Royal Colleges of Physicians and Surgeons, the British Medical Association, the British Hospitals Association and its committees, King Edward's Hospital Fund for London, and from the superintendents of three Poor Law infirmaries.

The Present Financial Position.

In the area covered by King Edward's Fund there are 117 voluntary hospitals of different kinds, including cottage hospitals; in the rest of England and Wales there are 728 hospitals, including general, special and cottage hospitals; in Scotland there are 107 hospitals; making a total for Great Britain of 952. The number of beds available in these institutions at the end of 1920 was approximately 12,797 in London, 31,265 in the rest of England and Wales, and 8,132 in Scotland—a total of 52,194. Besides these there are Poor Law infirmaries with some 92,000 beds, and a number of convalescent homes.

The financial position is gravest in the London area; in the provinces the conditions, though in some cases serious, are in general more satisfactory; while in the Scottish hospitals the outlook is more hopeful still. Reviewing the financial position as a whole the Committee comes to the following conclusion:

"While in certain areas and at particular hospitals the governing bodies have been able to encounter the difficulties caused by the war without permanent injury to the institutions under their care, the position of a large number of hospitals is such as to make it improbable that they can be continued on a voluntary basis unless prompt and vigorous measures are taken to re-establish the position of 1914. The receipts have not fallen off—indeed, they have increased; but the cost of provisions, drugs, dressings, fuel, and labour has grown to such an extent that it far more than counterbalances the increase of income. . . . Under these conditions we estimate that unless some remedy is found there will be deficiencies in the present year in respect of the hospitals in the whole of Great Britain, including London, amounting to not less than £1,000,000, and this without any provision being made for the necessary extensions and improvements. The position thus disclosed appears to us to involve danger to the whole of the existing hospital system."

The Committee's Proposals.

The Committee passes, therefore, to consider the steps that should be taken to meet this serious contingency, and a reasoned statement is given of the losses which might be incurred if the voluntary system came to an end. Convinced that this system is worth saving, any proposals for continuous rate-aid or State-aid are ruled out.

*Cand 1335 To be obtained from any bookseller or direct from H. M. Stationery Office. Price 4d. net

Nevertheless, if the hospitals are to be saved from immediate disaster and restored to the position of security they occupied before the war, it is held that some assistance must forthwith be given from public funds. This, however, should be temporary only, and on the understanding that it is not to be continued beyond a limited period—say two years. Neither should any grant be made except to a hospital which can show that it is doing its best to re-establish its finances, and that it has a fair prospect of so doing before the end of the period of probation.

In regard to the machinery for administering the proposed grant, the Committee recommends the setting up of a central body for Great Britain whose first and principal duty would be to dispense the temporary grants.

"This central body should be formed on the lines of the University Grants Committee, and might bear the name of the 'Hospitals Commission.' It should be appointed by the Minister of Health and should consist of not more than twelve members, of whom the chairman and three others should be selected by the Minister of Health and one by the Secretary for Scotland, and of the remainder one should be nominated by each of the following bodies, namely: The Joint Committee of the Red Cross Society and the Order of St. John of Jerusalem; King Edward's Hospital Fund for London; the British Hospitals Association; the Royal College of Physicians; the Royal College of Surgeons; the British Medical Association; and the Scottish Committee of the British Medical Association. Service on the Hospitals Commission should be voluntary, but it should be advised by a technical expert and will require a small clerical staff. Its expenses should be borne on the votes for the Ministry of Health."

In order to deal with local questions of finance and policy it is recommended that the Commission should have the assistance of committees with local knowledge and influence set up in each area; to these all applications to share in the grant should in the first instance be made. King Edward's Fund would perform this function for London; elsewhere the normal unit should be the county or county borough.

The Committee is impressed with the view, put before it by many witnesses, that the present lack of organization and co-operation among the voluntary hospitals not only detracts from their efficiency, but is the cause of much avoidable expenditure. Subject to certain exceptions in the case of teaching and special hospitals, the Committee sees no reason why arrangements should not be made both for defining the and promoting co-operation among them:

"If there were some body, such as a Voluntary Hospitals Committee, with authority to organize and grade the hospitals in a district and to act as a clearing house for patients requiring accommodation, a considerable saving might be effected."

Voluntary Hospitals Committees, being independent of the hospitals and able (by their control of grants or funds) to bring pressure upon hospitals

"would be in a position to collect information, to advise as to accounts and expenditure, to marshal appeals for funds, to act as a clearing house for patients, to promote the grading and the co-operation of the hospitals in their area, and to deal with the other matters referred to in the later paragraphs of this report."

Poor Law Infirmaries.

On the relations of the voluntary hospitals with the Poor Law infirmaries the Committee makes the following observations:

"We have been impressed with the volume and quality of the work carried out by the able infirmary officers whom we have seen, and it seems unfortunate that the abundant and varied clinical material in these institutions should be hardly used at all in the training of medical students. Further, we are informed that during the winter months there are, on an average, over 20,000 vacant beds for sick persons in Poor Law institutions, and that during the summer months the number increases to over 30,000; and it is very desirable that these vacant beds, many of which are suitable for general use, should, if possible, be used for reducing the long waiting lists at the voluntary hospitals. In a few instances the voluntary and Poor Law hospitals do to some extent work together. At Paddington arrangements have been made by which members of the staff of St. Mary's Hospital act as part-time officers of the Paddington Infirmary, and the laboratory work required by the infirmary is done at the hospital. At Lambeth the infirmary is visited by members of the staff of Guy's, and patients are sometimes transferred from one institution to the other. At Dudley Road, Birmingham, the guardians have expressed their willingness to allow students from the university to visit the wards. At

Wolverhampton it is proposed that the hospital should take over one of the pavilions of the infirmary (which is not required for Poor Law patients) and use it as an annexe to the hospital. But such instances are rare. It appears to us that it should be possible to make arrangements under which the staff and apparatus of voluntary hospitals should (so far as possible) be available for the treatment of infirmary patients, while the students at the hospital should be allowed to visit the infirmary wards, and the vacant beds at the infirmary should be at the disposal (on proper terms as to payment) of the hospital patients awaiting admission. Such arrangements could best be negotiated through the Voluntary Hospitals Committees when formed, or in London through the King's Fund; and, if statutory authority is required, it should be given."

Suggestions for Economy.

The Committee next suggests various steps which could be taken voluntarily by hospital managers to improve the financial position of the hospitals under their charge.

"With regard to the general expenditure in the hospitals, it has not been possible for us in the time at our disposal to make systematic inquiry. But the striking differences in expenditure between hospitals of like size and character appear to indicate that there is room in some cases for greater economy."

A series of paragraphs deal in turn with reduction of expenditure, uniform accounts, co-operative buying, removal of less serious cases to auxiliary hospitals, systematization of appeals for donations, collections from wage earners and contributions by employers, other contributory schemes—for example, those known as the Oxford and Sussex schemes—payments by patients, and the institution of staff funds.

Oxford and Sussex Schemes.

"The system of weekly contributions has been carried further by the Radcliffe Infirmary and County Hospital at Oxford, which affords an admirable instance both of the benefits of this system and of the advantages of hospital co-ordination. The Radcliffe, which is the only large hospital in the northern part of Oxfordshire and is connected with the medical school of the University, appears to perform the functions both of a 'secondary health centre' and of a 'teaching hospital' as defined in the interim Report of the Consultative Council on the Future Provision of Medical and Allied Services. It takes all the active cases for the Poor Law infirmaries in its district, and has succeeded in linking up with its work the primary and cottage hospitals and (to some extent) the district nursing service within its radius. And it has recently organized a scheme for obtaining weekly contributions, not only from workmen, but from the whole wage-earning population of the towns and villages in its area—and with conspicuous success. . . . We were informed that, although the scheme was only established in September last, there are already 35,000 supporters paying 2d. per week. . . . We are informed that the counties of Wilts and Hants are organizing schemes of a similar kind."

Voluntary insurance, called a Provident Scheme and Add . . . has been . . . Hove, and . . . Sussex . . . J. Gordon . . . Preston, and was described . . . Hospital. The scheme is confined to persons whose income does not exceed £250 per annum for a single member, £400 per annum for a man and wife without children or a widow with one child, and £500 per annum for a married couple with a family. The subscription for an unmarried person or a widow or widower without children is £1 per annum; married people without children or a widow or widower with one child pay a joint subscription of £1 10s. per annum, and married people with a child or children under 16 or a widow or widower with children under 16 pay a family subscription of £2 per annum. In the case of persons employed at works or factories, the amount is collected as far as possible by weekly deductions from wages. Members are entitled to free consultation and treatment at any of the co-operating hospitals, or, in the case of members unable to leave their beds, at their homes, but subject in the case of country members to payment of half the usual mileage rate from Brighton. The treatment includes ordinary dental treatment, laboratory and x-ray examinations, massage and electrical treatment when required. Urgent cases are admitted to hospital at once and others in their turn, but a member has no precedence over more urgent cases. Of the proceeds of the scheme one-fortieth is reserved for the cost of laboratory work, one-fortieth for x-ray work, one-fortieth for secretarial work, thirty-five-fortieths are divided among the co-operating hospitals on a basis determined according to an estimate of work done, and the remaining two-fortieths are retained until the end of the year and are then distributed among those hospitals which have had the heaviest calls made upon them. Of the sums paid to the hospitals 25 per cent. is placed in a fund which is at the disposal of their medical staff. The scheme is not yet fully established; but Dr. Dill estimates that if 100,000 members can be obtained, the financial problem of the co-operating hospitals will disappear. The main objection taken to the scheme is that it implies a contract on the part of the hospitals to provide such institutional treatment as subscribers may require; and if a large number of

contributors are secured it may be impracticable to provide the necessary beds without largely increasing the hospital accommodation or excluding non-contributors. But the scheme is interesting and well worth careful consideration, and we understand that its adoption in London and elsewhere is being considered."

Payments by Patients.

In regard to payments by patients—a plan already adopted, in one form or another, at a number of voluntary hospitals—the Committee sees no reason why this practice should not be generally followed, provided care is taken that the poor are not excluded from benefits primarily intended for them.

"We were informed that the increase of the weekly collections at Newcastle has not materially interfered with voluntary payments by patients; but this experience may not be general, and it is obvious that if any system of insurance (such as the Sussex scheme) were generally adopted, this source of income would become less productive."

"As to paying wards—that is to say, private wards where patients are received on the terms of paying the whole cost of maintenance and treatment—we doubt whether hospitals can look for any substantial increase of income by the establishment of such wards. Nor is it desirable that they should do so, since wards of this character occupy considerable space, and the experience of other countries goes to show that a hospital which makes a profit on paying patients is tempted to extend its paying wards to the detriment of the poorer patients. But there may be instances in which vacant space may usefully be filled in this way."

Insured Persons.

The suggestion that the cost of maintenance and treatment of insured persons in a voluntary hospital should fall upon the insurance funds appeared to the Committee to rest upon a misconception of the purpose and effect of the Insurance Acts. Medical benefit as defined in the Acts clearly does not include the more advanced treatment normally given in a hospital or the maintenance of an insured person as an in-patient. But while holding that the approved societies are thus not under any obligation to provide the whole cost of maintenance and treatment of their members in hospital, the Committee feels strongly that they do owe the hospitals a large measure of support, and the hope is expressed that the generous example of the National Deposit Friendly Society, in allocating one-third of its available surplus for hospital and nursing services, will be widely followed.

Payments by Public Authorities.

Coming to proposals for aiding the hospitals which would require legislative or executive action, the Committee deals first with the payments now being made by public authorities for services rendered. These fall under the following heads: (1) Pensioners; (2) tuberculous patients; (3) venereal disease; (4) maternity and child welfare; (5) school medical services.

"It has been suggested to us that these payments should be increased in amount. So far as our inquiries have proceeded, we think that the payments made, except in the case of school medical services, are generally reasonable; but there may be exceptions in certain districts. As the cost of treating these cases differs in different localities, we think it best that any negotiations as to the increase in the amount of existing payments should be left to be undertaken by the hospitals or the Voluntary Hospitals Committees when formed; and we therefore make no recommendation as to those payments."

"A considerable volume of evidence was given in support of a proposal that grants should be made for the training of nurses, who not only receive wages, but at many hospitals are boarded. This proposal was supported by half of the British Medical Association, who pointed out that nurses trained in the hospitals are regularly absorbed by the education authorities or by the general nursing service of the country. We think that grants for this purpose might be considered by the bodies having charge of the funds applicable for technical education."

A further point was made to the Committee by Mr. Bishop Harman in his evidence on behalf of the British Medical Association. He suggested, in effect, that the clinical notes of hospital patients should be collated, that there should be returns from every hospital, and that these should be collected and form part of the data for medical research; what the State is doing, so far as venereal disease is concerned, could and should be done generally. This suggestion is submitted by the Committee for the consideration of the Ministry of Health, and forms one of the recommendations.

Medical Staff Funds.

In connexion with the grants by public authorities the Committee refers to the practice which obtains in some hospitals of carrying a proportion (from 10 per cent. to 20 per cent.) of these grants to a staff fund which is placed at the absolute disposal of the honorary staff.

"In some of these hospitals, as at St. Bartholomew's, at the Royal Infirmary, Manchester, and at the Radcliffe Infirmary, Oxford, the fund has hitherto been applied by the staff to such purposes as the purchase of expensive apparatus or books, and the support of young practitioners taking up special branches of work; but in other cases the fund has been divided among the staff. The practice is supported by the British Medical Association on the ground that patients sent by a public authority are in the position of paying patients and that in the fees paid for such patients the medical practitioner is entitled to share. On the other hand, the honorary staffs of some hospitals are unwilling to share in such a fund; and two distinguished physicians expressed the view that if the medical staffs came to be subsidized to any substantial extent "the bottom would drop out of the voluntary system." It should be remembered also that, although the services of the staff are honorary, they obtain a valuable return in the form of medical and surgical experience and the enhanced reputation which accrues to a member of the visiting staff of a great hospital. If the system of carrying a percentage to a staff fund is confined to cases where the full cost of maintenance and treatment is paid by or on behalf of the patient, not much objection can (we think) be taken to it; but any extension of the practice beyond those limits appears to us to endanger the future of the voluntary hospitals."

Further recommendations are that the contributions by employers to hospital funds should be allowed as deductions from profits for income tax purposes; that hospitals be authorized to claim repayment of income tax when payment of a legacy is delayed for more than a year; and that legacy and succession duty on testamentary gifts be remitted.

Temporary Grants.

The question is then asked whether the new sources of income now being opened and the relief recommended in previous paragraphs will enable the voluntary hospitals to attain a stable financial position.

"We think they will; but the process must take some little time, and unless some temporary financial help is provided without delay from public funds some of them are likely to collapse. After most carefully considering the amount required, we recommend that Parliament be asked to sanction an immediate grant of £1,000,000 to be expended in assistance to such voluntary hospitals as are in need of it. The administration of the grant would be entrusted to the Hospitals Commission on the terms set forth above. This grant, if sanctioned by Parliament, should be looked upon, not as a windfall to be divided among all the hospitals or to be distributed equally over the different parts of the country, but as an ambulance fund to be applied at the discretion of the Commission to the relief of actual and pressing needs."

"It is probable that the grant suggested for 1921 will not of itself be sufficient to enable the hospitals to tide over the crisis, and that a further grant (possibly of less amount) will be required in 1922. But we think that it should be made clear that Parliament will not consider itself under any obligation, express or implied, to continue the grant beyond the latter year, and that the responsibility for maintaining any voluntary hospital after that time will rest wholly upon those who have the charge of the institution. We have every confidence that if the assistance recommended is given by the Exchequer it will be within the power of those having control of our hospitals, by means of economy in management and energy in interesting the public in their work, to maintain that voluntary system of which we are justly proud."

Lastly, the Committee recommends that the Hospitals Commission be authorized during a period of two years from this time to recommend grants for the extension or improvement of hospital accommodation.

"Any such grant to be subject to a contribution of not less amount being hereafter made from other sources, and no such grant to be recommended by the Commission except after consultation with the Voluntary Hospitals Committee of the area, and on that Committee being satisfied that full provision has been made for meeting any increase in yearly expenditure which may be consequent upon the extension or improvement. We estimate that a sum of £250,000 may be required for this purpose in the financial year 1921-22."

The report is signed by the Chairman and the other five members of the Committee—Lord Lintilhigo, Sir C. Hyde, Sir W. B. Peat, Mr. V. Hartshorn, and Mr. R. C. Norman. Besides Mr. Bishop Harman, Dr. H. G. Dain, Dr. J. R. Dreyer, Mr. W. McAdam Eccles, and Mr. A. E. Morison gave evidence on behalf of the British Medical Association.

British Medical Journal.

SATURDAY, JUNE 18TH, 1921.

THE VOLUNTARY HOSPITALS
COMMITTEE.

THE Committee on Voluntary Hospitals, appointed by the Minister of Health last January, under the presidency of Viscount Cave, to consider the present financial position of the hospitals in Great Britain and "to make recommendations as to any action which should be taken to assist them," is to be congratulated upon the expedition with which it has performed the work of the inquiry committed to it. Speed has not entailed a loss of efficiency, for a better balanced report of a Government Committee it would be hard to find. There is evidence of a very thorough inquiry, and a complete grasp of the complex problem involved. Moreover, the recommendations made are of such a character as we feel assured will commend them to every section of national opinion, even though they involve public expenditure—a serious matter in these days of high taxation.

The report shows what a great work is done by the voluntary hospitals, and at what a singularly low cost. The contrast drawn between this economy of private effort in hospital management and the cost of State or municipal effort is most striking. To acknowledge the truth of this is not to disparage State effort; the difference is now known to arise from the very nature of things. People of every status in life—poor folk, workpeople, business men, people of leisure, and physicians and surgeons alike—will do for a voluntary concern what they would not dream of doing, and, indeed, what they could not be advised to do, for a State or municipal concern. This willingness to work freely for a voluntary institution is due to the fact that there is a sense of possession of a share in it, which cannot be felt for a huge State machine; and it is particularly true of a hospital, which makes a strong appeal to the best instincts of all who have any bowels of compassion. We have read no more striking commentary on the different feelings entertained for voluntary and State hospitals than the citation (on page 10 of the report) from the evidence of Sir Anthony Bowlby, who said "There is the active sympathy and co-operation of the whole of the populace of this country with hospitals and hospital treatment. The subscribers, and their friends, are in constant touch with the hospitals; ladies visit them; there are ladies' committees and visiting committees; all sorts of opportunities to help poor patients, whether it be as regards clothing, instruments, or convalescent homes. All that, of course, is entirely lacking in the hospitals on the Continent, where there is no such help at all. There is no inter-communication; the hospitals are practically closed places, into which nobody goes except the people who are authorized." Such a commentary as this coincides with the opinion of those acquainted with the most strenuous efforts to sufficient to warrant the most purely British and retain a system which is so purely British and rooted in the very genius of our people.

From the standpoint of economy, or from that of sentiment, in whichever way the problem be viewed, from the extreme of hard shell matter of fact to the other extreme of human sympathy, the voluntary

hospital system is easily first. As a system it may be called illogical, much less defensible on that ground than a complete and unified State provision; but even in its failure in logic it is logical, for it conforms to human nature—at least to British human nature. Faults there are in the system; these are frankly owned to in the report. Voluntary effort in its beginnings was sporadic. It burst out here and there with intense energy. Pity is moved, and expression is given thereto in the practical fashion of the good Samaritan. It chanced that pity is aroused on the road to Jericho, and there the effort is made, without reference to the road to Damascus. The time has come when sporadic and unequal efforts must be stabilized and correlated, and the recommendation of the Committee that there should be closer working between the hospitals is well timed, and will receive the support of the medical profession. The experience of such methods gained in London, through the action of King Edward's Hospital Fund, proves that there need be no drag on the wheels of progress or wet blanket on the flame of enthusiasm.

The first recommendation of the Committee is that there should be a central Hospitals Commission for Great Britain, formed on the lines of the University Grants Committee. This is in accordance with the plan advocated by the Representative Body of the British Medical Association. The first duty of this central Hospitals Commission would be the administration of the temporary grants recommended, but it would be available for other purposes. The constitution suggested for it would give suitable representation of the medical profession, but we should need to be assured that a like representation would be secured for the profession on the local or county committees. The Branches and Divisions of the British Medical Association would be able and willing to help these local committees, for they have the means of finding the most capable practitioners for the work, as was shown by the methods adopted to man the Local Medical War Committees.

On the several items of the financial recommendations the most pertinent comment is that most, if not all, the suggested reliefs are debts owing to the hospitals. During the war the Government departments responsible for sending sick and wounded into the voluntary hospitals proved most hard-fisted paymasters. They sublet their work to the hospitals on terms that left the London hospitals alone with a loss of over half a million sterling! The National Insurance scheme would have been a hopeless failure medically and financially had it not been for the voluntary hospitals; without these the weight of sickness benefit alone would have crushed it.

In an interim report published last March the Committee recommended as a pressing matter that the schemes to be approved for the distribution of the surplus disclosed at the quinquennial valuation of approved societies under the National Insurance Acts should provide for the application of a substantial part of that surplus in making contributions towards the cost of the maintenance of members of the societies in hospitals. So far as we are aware no society, with the honourable exception of the National Deposit Friendly Society, has at present acted upon this recommendation. The insurance companies have saved money in workmen's compensation, and made profits, on the work of the hospitals, but have not moved one finger to ease the heavy burdens of the hospitals. Municipal authorities have turned to the hospitals for help and got it. Education authorities have used the hospital machinery at inequitable rates. The voluntary hospitals have sown good seed in the

training of a succession of nurses of the sick, and the nation and its services have reaped the increase but forgotten to return a tithe to the diligent producer. These are debts to the hospitals. They should be paid. And they can be paid without endangering that essential feature of the voluntary system—free and independent management.

On the matter of relief to the hospitals on rates, income tax, death duties, and the like, we need not comment, save to remark that a wise liberality with regard to these claims has in other countries attracted money to voluntary effort, to the great saving in national expenditure. The Committee has examined the contribution schemes for hospital support: the workshop contributory schemes in industrial areas, and the Oxford and Sussex schemes come under favourable review. Some of these are well established, and may be expected to develop still greater utility; others, such as the modified Sussex scheme which is under consideration for London, are planned so as to be an insurance for hospital benefit, and raise far-reaching issues. So far, these schemes are in their infancy; the response of the people is yet to be seen.

The service of the medical staffs to the voluntary hospitals is commented upon in more than one part of the report; its value, its assiduity, and free character, are recognized, and the report contains what is, we believe, the first lay commentary on the "Medical Staff Fund Scheme"—the scheme of the British Medical Association for carrying a proportion of the grants for State and municipal patients to a staff fund which is placed at the absolute disposal of the honorary medical and surgical staff. The Committee's opinion is that "if the system of carrying a percentage of a staff fund is confined to cases where the full cost of maintenance and treatment is paid by or on behalf of the patient, not much objection can (we think) be taken to it; but any extension of the practice beyond those limits appears to us to endanger the future of the voluntary hospitals."

Of Poor Law infirmaries the Committee says that while it has been impressed with the volume and quality of the work carried out by infirmary officers, it is unfortunate that the abundant and varied clinical material in these institutions should hardly be used at all in the training of medical students. The estimates that during the winter months there are, on an average, over 20,000 vacant beds, and during the summer months over 30,000, are accepted, and the opinion is expressed that many of the vacant beds are suitable for general use and should be used for reducing the long waiting lists of the voluntary hospitals. The Committee goes on to suggest that one of the duties of a local Voluntary Hospital Committee should be to make arrangements under which the staff and apparatus of voluntary hospitals should be available for the treatment of infirmary patients, that students should be allowed to visit the infirmary wards, and that vacant beds at the infirmary should be at the disposal, on proper terms as to payment, of hospital patients awaiting admission.

We have summarized the report elsewhere in our columns this week. Nevertheless we would urge members of the profession to read the report in its entirety. It can be obtained through any bookseller for 4d. It is worth reading.

Finally, we would suggest to the powers that be, Parliament and the Cabinet, that what they would do they should do quickly: there is salvage to be made. The proposed temporary grant is not a dole but the payment of an overdue debt. Paid now, it will free the voluntary hospitals from a debt that is dragging

them down like a millstone about the neck and threatens to drown them. Freed from that, they, their executives, supporters and well-wishers will regain a buoyancy which will draw into their wake a new generation of supporters.

OPERATIONS FOR GENITAL PROLAPSE.

THE British Congress of Obstetrics and Gynaecology, held at Birmingham on June 3rd and 4th, a report of which is published in our present issue, was, from more than one point of view, an event of great importance to obstetricians and gynaecologists. The Congress was the first which embraced all the British obstetrical and gynaecological societies, and its success, viewed from every standpoint, was such that it is practically certain to be the first of an annual series.

The chief topic discussed—namely, "The end-results of plastic vaginal operations for genital prolapse"—is one of the greatest importance to all gynaecologists, as well as to the general practitioner who will sooner or later be called upon to advise patients with regard to operative treatment. It is therefore well to have an authoritative pronouncement from such a representative body of gynaecologists as those who took part in the discussion regarding the relative values of the vaginal and the abdominal methods of treatment. At the outset it may be said that a motion had been put down to the effect that "this meeting condemns the use of abdominal operations as unnecessary in the treatment of genital prolapse," but it was felt by a majority of the large assembly present that such a motion would, to a greater or less extent, interfere with freedom of debate, and consequently it was withdrawn before the discussion started. We cannot therefore record a definite pronouncement but only a general impression regarding the trend of opinion, and this will be referred to hereafter.

The three opening papers, by Dr. W. E. Fothergill, Dr. Lacey, and Professor Donald, were commendably brief and lucid. Professor Briggs of Liverpool was in the chair, and by his judicious enforcement of a rigid limit of ten minutes to the subsequent speeches it was possible to obtain within the short space of three hours a kaleidoscopic representation of the views of a large number of the leading gynaecologists of Great Britain. It is important to note, in the first place, that the results of the plastic operation given by Drs. Fothergill and Lacey pertained to cases operated upon during the years of war 1914-15-16, when it would naturally be expected that, owing to stress of work and to the fact that sometimes the actual operations had to be performed by relatively inexperienced surgeons, the after-results of operations would not be the best obtainable under more ideal conditions. In the second place, the patients were women of the working classes, employed in cotton mills or engaged in other laborious occupations, and therefore under the necessity of returning to work after the shortest possible period of convalescence. Taking these two facts into consideration, as well as the fact that no case was included which merely required perineorrhaphy, Dr. Fothergill's 97½ per cent. of cures and the 87 per cent. of cures in the cases followed up by Dr. Lacey speak for themselves. Furthermore, when Dr. Lacey's results are examined more closely the 87 per cent. of cures becomes in reality much higher. Thus out of the 521 replies received, 455, or 87 per cent., answered the question, "Does the womb keep up well now?" with an

emphatic "Yes." Of the remaining 66, 29 were examined, and if 2 cases of hypertrophic elongation of the cervix are excluded, in both of which amputation should have been carried out at the time of operation, only 5 cases remain in which any anatomical abnormality could be discovered. Assuming that the same proportion of anatomical cures would have been found in the whole 66 had they attended for examination, we seem justified in concluding that only in 11 cases, or about 3 per cent., was the operation a failure. A study of the causes of failure in the 3 per cent. shows that, owing to the presence of such conditions as chronic bronchitis, certainly no better results could have been obtained had ventrofixation been done in addition to the vaginal plastic operation, and it goes without saying that ventrofixation *without* reconstruction of the damaged pelvic floor by the vaginal method must have resulted in a much smaller proportion of cures, whether symptomatic or anatomical.

A consideration of the views of those who took part in the subsequent discussion shows very definitely the almost unanimous opinion to be that in a very large proportion of cases, say 97 or 98 per cent., operation by the vaginal route was sufficient, and intervention by the abdominal route unnecessary and undesirable, increasing the risk and discomfort to which the patient was exposed. In a few cases—especially those in which complications existed, such as adhesions in a retroverted uterus, and perhaps also in cases of congenital prolapse in nulliparae, where all the supporting structures are loose and ill nourished—better results could perhaps be obtained by combining the abdominal and vaginal operations. It is, however, evident that such complications as adhesions and diseased ovaries and tubes are not prolapse at all, and may not even be complications of it; even Dr. Fothergill and his most ardent supporters admit the necessity for abdominal operation with a view to dealing with such conditions.

Professor Donald described the stages by which the present perfected plastic vaginal operations were evolved from the crude methods in use in Edinburgh in the early eighties, when all that was aimed at was so to repair the damaged tissues as to enable the patient to retain a pessary—an evolution in which Professor Donald himself has played a main and distinguished part. This is a record of which British gynaecologists in general, and those of the Manchester school in particular, have good reason to be proud.

PROFESSIONAL SECRECY IN COURTS OF LAW.

In a case heard before Mr. Justice Horridge in the Divorce Court on June 9th the question of venereal disease arose, and counsel for the husband called Dr. John Elliott of Chester, who had treated the wife. Mr. Barrington Ward, K.C., raised the question whether Dr. Elliott was bound to give evidence. The judge asked whether any authority could be shown for counsel being heard merely on behalf of a witness. Mr. Ward replied in the negative, whereupon the judge declined to hear counsel. Dr. Elliott on entering the box asked the judge to exempt him from giving evidence with regard to venereal disease. Dr. Elliott said that he and other medical men had undertaken duties at the clinic on the distinct understanding that professional secrecy as to what happened there would be observed. The judge asked whether the witness could show any statute which upheld that contention. Dr. Elliott referred to Article II (2) of the Public Health Venereal Disease Regulations of the Ministry of Health, which provided that "all information obtained in regard to any person treated under a scheme approved in pursuance of this Article shall be regarded as confidential." The judge said the Ministry

had no power affecting the jurisdiction of the courts: doctors were subject to the orders of the court and must disclose what they knew. Dr. Elliott, while not contesting the ruling, observed that he was placed in a painful position. The Judge retorted: "I cannot see any painful position about it. You are bound to observe the regulations not to disclose voluntarily information you have obtained; but, so far as giving information which you are bound to give in assisting the administration of justice, it is your duty to give it." Dr. Elliott said: "We do not undertake not to disclose voluntarily, but not to disclose at all. It is one of the tenets of the medical profession that confidence must obtain between doctors and patients." The Judge: "But it is not an unfair obligation on doctors to assist in the administration of justice." Dr. Elliott said: "There is another point—that is, the effect of not keeping these proceedings secret." The Judge: "I have nothing to do with that." Dr. Elliott: "Very well, I have nothing further to say. I must bow to your ruling and give evidence." It would appear therefore that, unless Parliament interferes, the undertaking given by the Ministry of Health in the Public Health Venereal Disease Regulations, which have been approved by Parliament, has become of no effect. In the course of a letter on the subject Dr. J. S. Manson of Warrington writes: "The analogy between the doctor who knows, and the lawyer who knows, may be incomplete, yet it is sufficient to set up a certain feeling of injustice or inferiority in the medical profession as compared to the legal profession in the matter of professional secrets. This, however, is a minor point compared with the doctor's conception of his duty to his patient. The patient, anxious for his mental and physical welfare, unburdens his soul and submits his body to the examination of the doctor, and he is entitled, even as part of the treatment, that the information so obtained should be kept secret, and, except for the gravest of public reasons, such as the detection of serious crime or the spread of serious epidemic disease, the doctor should not be compelled to divulge. The decision of this conflict between the duty of a perplexed and conscientious doctor to his patient and his duty to the public should not be left in the hands of a single lawyer, however eminent, but should be referred to a small committee of the House of Lords, composed equally of eminent medical men and lawyers, for their decision. If some such scheme as this were adopted, it would soon be found that in actual practice much of the medical evidence now required in unimportant cases could be dispensed with, while the public welfare would be safeguarded by the necessary medical evidence in the serious and important cases."

ACQUIRED IMMUNITY AFTER EXPERIMENTAL MEASLES.

In a previous communication, noted in the BRITISH MEDICAL JOURNAL (April 2nd, p. 500), Blake and Trask, of the Hospital of the Rockefeller Institute for Medical Research showed that a condition closely resembling measles in man could be induced in monkeys by the intratracheal injection of filtered or unfiltered nasopharyngeal washings from human patients in the prodromal or early eruptive stage of measles. In order to determine whether experimental measles protects, as human measles does, against a second attack, a series of reinoculation experiments¹ have been carried out on monkeys which had recovered from experimental measles. Monkeys were injected intratracheally with material containing the virus of measles, and other monkeys were intravenously injected with whole blood withdrawn from a monkey on the third day of experimental measles. None of these re-injected monkeys showed any evidence of infection with the virus of measles, and, as they were with one exception injected with a strain different from that originally employed it seems to follow that the immunity conferred by experi-

¹ T. G. Blake, M.D., and J. D. Trask, jun., M.D., Journ. Exper. Med., Baltimore, 1921, xxxii, 621-625.

mental measles is, as in man, as efficient against a heterologous as against the homologous strain. Further, this would suggest the probability that all strains of the measles virus are of a homologous strain in as far as their property of stimulating immunity is concerned. As monkeys injected intravenously with the virus remained immune, it appears that the immunity is not solely, if at all, dependent upon a possible barrier offered by the respiratory mucous membrane of a monkey that has recovered from experimental measles.

CATARACT IN IRON WORKERS.

THE fact that cataract is peculiarly liable to develop in glass-workers is well known, and much information on the subject has been published from time to time in our columns. Evidence is now advanced that iron workers are also unduly liable to cataract. Three papers on the subject are published in the *British Journal of Ophthalmology* for May, 1921. Cridland, of Wolverhampton, deals with cataract in puddlers, among whom the cases are comparatively few. He points out that the number of puddlers is by no means large, and is likely to decrease in the future, as steel replaces puddled iron. His contribution adds a few details to the well-known paper which he published on this subject in 1915. St. Clair Roberts has collected notes on cases of cataract occurring in chain-makers at Dudley. In all he found a posterior polar and cortical opacity very similar to that described in glass-blowers. In describing the method of chainmaking by hand, he states that machines for making chains have not proved successful, and he tells us that it is a common belief among the workers that the sight should fail between the ages of 50 and 60. In uncomplicated cases there is no associated lesion of the fundus, and the results of operation are good. The most comprehensive of the three papers is that by Healy of Llanelli, who, having previously had experience of bottle-makers' cataract in Sunderland, has produced really valuable statistics of the number of cataract cases occurring in men of 35 years of age and over engaged in the tinplate industry at Llanelli. He also describes the nature of the work at length, and gives details of 209 cases. In his cases the posterior cortical type of opacity often existed in combination with cortical striae. His paper strongly confirms the supposition that it is the infra-red heat rays which are the important ones in the etiology of this condition, for in the tinplate mill the men are not exposed to ultra-violet rays. The atmosphere of the mills is dusty, and the men perspire freely; they are adverse to the wearing of protective goggles, but Healy believes that much might be done by suitable propaganda to overcome this prejudice. This series of papers offers weighty evidence in favour of the suggestion that cataract in iron-workers should be scheduled under the Workmen's Compensation Act, as well as glass-makers' cataract. The Glass-workers' Cataract Committee of the Royal Society has sent a deputation to Llanelli to inquire into Dr. Healy's cases, and there is reason to hope that the Home Office will shortly place these trades upon the schedule. These papers appear to us to be amongst the most important contributions to ophthalmology that have recently been published.

THE APOTHECARY POET.

ON October 29th, 1895, in celebration of the centenary of the birth of Keats, the late Sir William Osler read before the Johns Hopkins Historical Club one of his attractive biographical essays, that on *John Keats, the Apothecary Poet*, and it is appropriate that Sir George Newman, an honorary Freeman of the Apothecaries' Society, should now dedicate to the Master of that City Company a charming and critical study of *John Keats, Apothecary and*

Poet, on the centenary of his death. After his mother's death from tuberculosis, Keats, then 15 years old, was apprenticed for five years to a surgeon at Edmonton; but in 1814, more than a year before his time was up, he entered at Guy's Hospital, and in 1816 passed the examination for the Licence of the Apothecaries' Society with credit. After this he never attempted any further medical work, though on one or two occasions, when disheartened with the reception of his literary labours, he toyed with the idea of practice. What influence was exerted by medical training on the poet's mind is an interesting question; although his poems and letters do not reveal any obvious impress from the six years of professional study, it is difficult to believe that his sensitive and responsive mind was unaffected thereby. Thus, though a born lover of nature, he appears in his written remains as a trained and acute observer with a sense of thoroughness, a desire for system, knowledge, and philosophy, a wide sympathy with human suffering, and a fuller comprehension of the part played by health and disease in human affairs. The first of his printed poems, "The Imitation of Spenser," was written at the age of 17, and the last appeared in 1820—a period of eight years; nearly the whole of his output, however, was concentrated into a brilliant space of half that length. "Endymion" saw the light in 1818, and the immortal volume containing "Hyperion," "Lamia," "Isabella," "The Eve of St. Agnes," and the five famous Odes came out in July, 1820, when the author lay dying from tuberculosis, almost certainly contracted when nursing his brother, who had succumbed in 1818. As a boy his genius was awakened by Spenser's "Faerie Queen," and he became an inspired and imaginative interpreter of Nature for her own sake. In forsaking the apothecary's calling he adopted the yet nobler mission of repairing the sorrows and wounds of human lives by the healing power of beauty. Lastly, Keats was a philosopher—and, indeed, in one of his letters boldly describes himself as a philosopher first and a poet afterwards. Sir George Newman sums up Keats's philosophy as follows: "That beauty is truth; that such truth is power; that such power moulds the soul; and that the purpose of the soul is devotion to human service through personality."

THE FATE OF THE LYMPHOCYTES.

THE function and fate of the lymphocytes, which mainly enter the blood by the thoracic duct, are still unsettled. In dogs it has been estimated by P. Roux that the surprising number of 3,300,000 lymphocytes pass into the blood during the twenty-four hours, and that this exceeds the total ever present in the blood at one time. The interesting problem as to the fate of the lymphocytes has been investigated by Bunting and Huston,¹ of the University of Wisconsin. That the lymphocytes become transformed into other forms of leucocytes, as was once believed, is opposed to modern haematological teaching, and such an explanation of their disappearance need not be further considered. Bunting and Huston's experiments on rabbits showed that a billion or more lymphocytes enter the blood from the thoracic duct in the twenty-four hours, and that in six hours 443,000,000 lymphocytes disappear from the circulation. Stained films may present occasional disintegrating lymphocytes, but further experiments proved that there is not, in this way, the rapid destruction that would be necessary to explain the rate of their disappearance from the blood when their supply is cut off by ligation of the thoracic duct and splenectomy. The remaining possible explanation is that the lymphocytes leave the blood; there is not enough lymphocytic accumulation in the tissues to justify the view that they escape in

¹ John Keats, *Apothecary and Poet*, by Sir George Newman, K.C.B., the Society of Apothecaries of London, 1921. (Pp. 36, 1s.)

² C. H. Bunting and J. Huston, *Journ. Exper. Med.*, Baltimore, 1921, xxxiii, 593-620.

this direction, and there is not any evidence of their destruction in the tissues. Microscopic examination of the organs led to the conclusion that the majority of the lymphocytes enter the mucous membrane of the gastro-intestinal tract and pass through into the lumen; this lymphocytic migration takes place not only from the blood but from the lymphoid nodules and patches, which are seen in sections to be delivering lymphocytes to the intestine on one side and to the afferent lymphatics and so en route for the thoracic duct on the other side. We therefore appear to be brought to the conclusion that in normal conditions the lymphocyte largely fulfils its function upon the surface of the intestinal mucosa; what this function may be is unknown, but the immunity of the gastro-intestinal mucosa to the countless bacteria and their toxins within its lumen suggests the possibility that the lymphocyte may affix toxins.

BRIGHT'S LESS KNOWN CONTRIBUTIONS TO MEDICINE.

In an account of the observations other than those on renal disease made by Richard Bright, whose rare ability to observe was fortunately accompanied by admirable descriptive powers, Sir William Hale-White¹ remarks how much better it would have been if some modern authors had transcribed Bright's description of a disease instead of painting the picture themselves. A corresponding plan has often been advocated and adopted as regards sermons, and it is hard to believe that medical writers have not borrowed generously, though not quite verbatim, from such an authority as Bright. To this industrious observer, who sought out the secrets of morbid anatomy and avoided speculation, no trouble was too great to obtain an important necropsy, and for this purpose journeys into the country, in his day very tedious, were cheerfully undertaken. His original observations ranged over a wide field, and included the nervous system, the abdomen, heart-block, and the administration of oxygen. Thus he noted hemiopia in cerebral haemorrhage, described lateral sclerosis of the spinal cord in spastic paraplegia, discussed what was later known as Jacksonian epilepsy, and insisted on the association of chorea and rheumatism. In the Lumleian lectures on disorders of the brain delivered in 1837 he drew attention to the connexion between pericarditis and chorea; the lectures were never published, but, according to the late Sir Samuel Wilks, they contained the first description of a mitral murmur in chorea. Among his numerous contributions on abdominal disease, the most original is that on the occurrence of excessive fat in the faeces of patients with pancreatic carcinoma ulcerating into the duodenum; this was based on three cases, one in a woman aged 21 years only. In the first volume of the *Guy's Hospital Reports* he recorded three cases of acute yellow atrophy of the liver under the title of diffused inflammation of the organ, the present name being applied by Rokitsansky in 1842; Bright's account, though not the first, as a reference to Dr. Wickham Legg's classic *Bile, Jaundice, and Bilious Diseases* will show, forms an important landmark in the history of this rare and still rather mysterious disease. It is interesting to learn that Bright anticipated his colleague, Thomas Addison, in so far that he described a case of bronzing of the skin, in which the chief morbid change was disease of the adrenals, but apparently he did not associate the symptoms and the lesion, and so Addison's claim to the discovery of the disease (1855) remains unchallenged. Sir W. Hale-White, who has done so much to throw light on the etiology and clinical picture of simple chronic peritonitis, considers that the first description of this condition was probably that given by Bright. Of a joint work on *The Elements of the Practice of Medicine* one volume only appeared (1839), and this is generally regarded as mainly

the work of Addison; but however this may be, it is remarkable for containing a description², which Howard Kelly seventy years later said "could not be surpassed to-day," of the now common disease which was named appendicitis by the late R. H. Fitz of Boston, U.S.A., in 1886.

MEATLESS DIETS.

THE Vegetarian Society of Manchester has published a pamphlet on vegetarian athletics,¹ written by Mr. Henry Light, who is described as captain for twenty years of the Vegetarian Cycling and Athletic Club. We are glad to see that he is no extremist, but one who recognizes the value of moderation both in opinions and in their expression. He presents first a formidable list of eminent athletes who have given up a meat dietary, and if we can trust the statements about their food intake (and non-scientific people are apt to take but scant account of accuracy without any intention to deceive) there is good testimony as to the value of their present system. But this does not mean that they were strict vegetarians. We believe it is usual to dub their dietary "Vem" (vegetables, eggs, milk, including milk products, for example, cheese). There is no physiological reason why such a diet should be inefficient if taken in properly balanced proportions. Towards the close of the pamphlet the question, What constitutes overfeeding and underfeeding? is raised. To answer such a poser we should have to explain the whole of the principles of nutrition, and that is beyond the scope of this note. Suffice it to say that the amount must depend on the age, size, and activities of each individual. The main factor that causes variation in an average adult is the amount of work he does. The energy-supplying food (fat and carbohydrate) must be proportioned to this. The supply of the protein food which builds tissues and repairs waste is a much more constant figure unless actual growth is in progress. There is no reason why all this should not be supplied by the vegetable world. The usefulness of meat in a dietary depends on what Rubner called the specific dynamic action of protein, and of all proteins those of animal flesh are most efficacious in this direction. But if meat has a specific action, the vegetarians can claim (what they have omitted to do in Mr. Light's article) that plants have also a specific usefulness in supplying to animals those accessory factors known as vitamins, which are indispensable to health and even to life itself.

CHILDREN'S DREAMS.

DREAMS are a source of perennial interest. To the foolish they are omens of profound import. To the wise they are a subject of curiosity and provide room for thought and memory searching in an effort to discover what brought them about. Both wise and simple are influenced by them, for a happy morning waking dream means a fair start for the day, and a nightmare a gloomy breakfast. The dreams of our childhood were as real a matter as the facts of our daily experience, and the meaning of these in the physiology of the child mind, has been studied by Dr. Kimmins, and his results have now been published in a small volume.² His investigations were made upon London elementary school children. His method was to secure their narration individually by the younger children to skilled observers, and to arrange that all dreams of children over 8 years of age were recorded by the dreamers themselves in response to the request, "Write a true and full account of the last dream you can remember. State your age, and also say about how long ago you had the dream you have described." Some 6,000 records were obtained from children aged from 8 to 14 years. He notes that in spite of fear dreams, children in normal health delight in dreaming, and it is an evident pleasure to them

¹ The Vegetarian Society, Manchester. 3d.

to talk about and record their dreams. There is also a remarkable power of graphic description which exceeds their ability in ordinary essay writing and is so much in advance of their general standard of achievement that it would appear as though some fresh element had come into play. Dreams are far clearer and more vivid in the calm country than in the noise of London. Change of environment stimulates, and hard mental work increases the tendency to dreams; a stuffy bedroom diminishes their clearness. Persons of well-developed intelligence dream far more frequently than those of low culture. Dreams of motion, falling, flying, are rare under the age of 9 or 10 years; they then increase in frequency up to the age of 17 or 18. Regular institutional life tends to diminish this type of dream; the deaf scarcely ever experience it; febrile states accentuate the liability greatly. The fear dream is very common in quite young children; 25 per cent. were of this nature, and were chiefly of the dread of objectionable men; the fear of animals was more common amongst boys than girls. School activities appeared little in the dreams of children of any age. Air raids figured little, for the last of them occurred seven months before the investigation was made. Domestic occurrences and fairy dreams delight the girls, rarely the boys. The dream ghost has almost vanished. In dreams of adventure, common with boys, the dreamer is usually the hero or heroine. Amongst the blind and deaf dreams are lacking in variety; fear dreams are excessive—fear of animals particularly with the deaf, fear of fire with the blind; to the blind the air raid was a far greater terror than to the normal child, and the impression of it extended to a year after the last raid; for the deaf the raid had no terror. The dreams analysed afford no evidence that a child blind from birth ever sees as a dreamer, but abundant evidence that those who have recently become blind see clearly. It is suggested that a careful study of children's dreams may throw much light on the special interests and desires of the child at different ages, and (especially where dreams of unfulfilled wishes recur persistently) on those elements which are conspicuously lacking in the life of the child, and may seriously interfere with his natural development. Of these, the most obvious are dreams which indicate underfeeding and those which give evidence of stress and strain.

THE CENSUS.

THE Census, which was postponed from Sunday, April 24th, on account of industrial troubles, will be taken on Sunday next, June 19th. The schedule of inquiries contains several new features, the full intention of which cannot be gauged solely by the headings. The new Census paper is certainly more complicated than its predecessors, and many householders will find it troublesome to fill up. For the first time particulars of age are sought in years and months. The reason for this is that some people have filled in the space in round figures, such as twenty, thirty, and forty-five. The fresh demand is for precision. The question about divorce was not asked in previous censuses, but it is felt that statistics are important as touching the care of children, besides which the matter needs to be cleared up, for divorced persons have hitherto returned themselves haphazard as either single or married, and all the marriage figures are made unreliable to this extent. Another column is intended to bring out whether both parents are living, or whether either is dead, in order that accurate information may be obtained as to the number of orphans in the country. The section for details of birthplace and nationality contains alternative columns, the second requiring persons not born in the United Kingdom to state whether they are visitors or residents in this country, and of what nationality if born in a foreign country. Under the heading "Personal Occupation" a person in employment must make clear not only his occupation, but the kind of industry in which he is engaged; the name and address

of the employer are to be added, but they will not be published. In this way it will be ascertained that a carman, for example, is employed by a firm of woollen weavers, and is thus connected with the textile industry. The statistics of occupation will be of value from the standpoint of health by bringing out comparative knowledge of the working conditions of different portions of the community. The particulars as to the industries absorbing service will be more useful for economic purposes. In the alternative column persons out of work are to say so, and thus an aggregate total as to employment will be secured. "Place of Work" forms a new inquiry which has been suggested by the important problems of housing and transport. In the past the Census has shown how many persons dwell in different areas; in future it will show where they work. It is hoped thus to learn the daily tide of movement between people's homes and their places of work, its direction, range, and volume. It is believed that such knowledge will be of use in drawing conclusions as to where houses and continuation schools are most needed. Under the heading "Personal Occupation" information is sought in regard to the education of each child, whether part-time or whole-time. Another section, applying only to married men, widowers, or widows, gives a table for the number and ages of all living children and step-children under 16, whether already enumerated or not—that is to say, whether residing in the family or elsewhere. This is inserted with a view to ascertaining the amount of dependency upon various classes of men and women and various occupations or industries. Yet another provision will furnish an index to housing and therefore to health conditions: the enumerator is to note the number of living rooms occupied by each family. Householders in Wales and Monmouthshire will be asked how many persons in the family are able to speak both English and Welsh, or English only or Welsh only. For the present Census the number of districts is close upon 38,000 for England and Wales, or 2,000 more than at the last Census. In the official pamphlet of instructions an account is given of the process of Census-taking, and of the special machinery provided for punching cards, which, thus prepared, will be manipulated by sorting and counting machines for various purposes. The sorting machines are capable of distributing cards into ten receptacles at the rate of 15,000 to 20,000 an hour. Lastly, we may note that the object of the Census is thus defined: it is "to obtain reliable figures of the population of the country, showing how that population is made up, that is to say, of what sorts and conditions of people it is composed and how it is distributed through the local subdivisions."

COLONEL THOMAS SINCLAIR, C.B., Professor of Surgery in Queen's College, Belfast, is among the twenty-four members elected to the Senate of the Parliament of Northern Ireland; and Sir Thomas Joseph Stafford, Bt., C.B., F.R.C.S.I., Deputy Lieutenant and late Medical Commissioner, Local Government Board, Ireland, is elected to the Senate for the Southern Parliament.

REPRESENTATIVES of the Rockefeller Foundation are at present in this country to discuss the extension of the Foundation's activities in the investigation of tropical parasitic diseases. Hitherto the Foundation has been concerned chiefly with ankylostomiasis, but it is intended to take up other subjects, and the British Colonial Office has promised every facility. Meanwhile, Dr. Victor G. Heiser, one of the representatives, is proceeding at once to India with the view of studying the prevalence of ankylostomiasis there. The other representatives are Mr. George E. Vincent, President of the Foundation, and Dr. Wickliffe Rose, general director of the International Health Board.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Naval Medical Vote.

IN Committee of Supply on Naval Estimates, on June 8th, a resolution was reported for a sum not exceeding £720,500, to defray the expense of medical services, including the cost of medical establishments at home and abroad, which will fall due before the end of March, 1922.

Commander Bellairs said he understood that the representatives of the army and navy were meeting together under the presidency of the Lord President of the Council. He desired, if possible, that Admiralty representatives should meet representatives of the War Office to see whether they could not effect economy by amalgamating the medical arrangements of the army and navy. He found, in the case of Hong Kong, that the military hospital there had accommodation for 166 patients, and the maximum number accommodated was 64, showing a surplus accommodation of 102. The minimum number of patients accommodated was 20, which gave a surplus of 146. Similar figures were shown in connexion with the naval hospital, which had accommodation for 135 patients, while the maximum number accommodated was 97 and the minimum 55. The Yokohama Naval Hospital, also on that station, was closed all through the war and right up to 1920, and it had now been reopened. He urged a thoroughgoing inquiry to prevent overlapping between the two services. There was no difference between the body of a sailor and the body of a soldier so far as medicine was concerned. He believed that the House would be shocked if it were to investigate the number of medical men, say, on the China station, and the number of men whom they had to treat. There were also convalescent barracks at Hong Kong for the military.

Sir Godfrey Collins supported the appeal made by the previous speaker, drawing attention to the case of Malta, where the naval and military had separate establishments side by side. He thought that if the army and navy had combined hospital accommodation it would be to the advantage of the services and the taxpayers. He asked, further, why the Admiralty had refused to adopt the recommendation of the Select Committee on National Expenditure to present their accounts to the House of Commons in the modern method. The War Office had accepted that recommendation, and their accounts revealed the cost of patients in every hospital under the War Office, whereas it was impossible to find, from the Naval Estimates, whether the medical establishments of the latter department were efficiently managed.

Mr. Amery, in reply, said the suggestion for amalgamating naval and military hospital work at certain stations abroad was one that naturally at first sight would appeal to the House. He would certainly look into it, but members would realize that the conditions of naval and military service and discipline and many of the aspects of their organization were so different as to make it not altogether an easy thing to carry out this amalgamation. He imagined, however, that there might be some stations where a military hospital could provide for a certain limited number of naval patients, and *vice versa*. With regard to the particular case of Yokohama, he had not only asked for a close investigation as to the cost of that establishment but also as to the possibility of getting some military establishment elsewhere to take up the patients who went to Yokohama. The War Office was at present the only department which had adopted the new method of accounting. The Admiralty was considering the whole question of their system and had before them a report by a Committee presided over by Colonel Gretton.

The vote was afterwards agreed to.

Coroners' Remuneration Bill.

This measure, which was introduced by Sir Thomas Bramsdon as past President of the Coroners' Society for England and Wales, went on second reading to Grand Committee, where Sir John Baird, on behalf of the Government, promised that if the bill was proceeded with, amendments should be made to secure a revision, and not merely an increase, of the salaries of coroners. On June 10th the bill came on report before the House of Commons, when a number of changes were proposed.

Sir Thomas Bramsdon explained that coroners for counties were paid by salary which was arranged by Act of 1860. Coroners for boroughs were paid by fees—£1 6s. 8d. for each inquest held; statute, the last increase having been made in 1860. A borough coroner thus got nothing unless he actually held an inquest, whatever inquiries of a preliminary kind he might make; if an inquest lasted three or four days his fee was still limited to £1 6s. 8d. No alteration could be made while the law remained as at present. The legislation now proposed was intended to be temporary. A strong Departmental Committee, appointed in 1909, had recommended a revision in the pay of coroners. Sir Thomas Bramsdon added that borough coroners had no allowances; the sum of £1 6s. 8d. included clerk's fees, postages, and other incidental expenses.

Sir John Baird, in explaining the attitude of the Government,

said it was felt that coroners had a claim to consideration. As regards borough coroners, he agreed that what was adequate in 1887 could not be deemed so to-day. As regards county coroners, he pointed out that, under the statute by which the quinquennial valuation takes place, the authorities have no power to consider higher cost of living, travelling, and other expenses, but had to revise solely in reference to the number of inquests held. It was now intended that all relevant matters should be taken into account.

The bill as it came down from Committee proposed that local authorities should proceed to revise the rates of salaries or fees payable to coroners, or, in other words, that an obligation should be imposed, and on this Sir Frederick Banbury moved an amendment to alter the words "shall" to "may," and this was carried by 74 votes to 49. Later he carried the deletion of a part of a subsection of the first clause, which provided that the Home Secretary should fix salary or fees if the authority and coroner failed to agree. Another provision in the bill that the fees should be revised so as to be increased by not less than 50 per cent. was consequentially struck out, and the measure was afterwards given its third reading as a permissive bill, the real effect being that if it becomes a statute it will remove the provisions at present existing against the revision of fees or salaries by local authorities.

The Dentists Bill.

Through the unexpected lapse of other business, the Dentists Bill was taken on report in the House of Commons on June 13th.

Sir Alfred Mond (Minister of Health), meeting an objection by Colonel Wedgwood, pointed out that it was only on the understanding that this was a more or less agreed measure that the Government had adopted it; that there had been fairly full discussion in Grand Committee; and that if any member who had not put down notice of amendment on report (though there had been time) made a case for one, it could be put forward in another place.

Colonel Wedgwood, on the first clause, moved the adjournment. The report of the Departmental Committee upon which the bill was founded included, he said, a great deal more than a proposal to place dentists in the same category as doctors—that is, as a closed corporation. There were recommendations for a free dental service, and for some form of scholarship to enable children of the working class to become practitioners. Mr. Seddon, supporting the appeal of the Minister of Health, spoke of the excellent spirit manifested upstairs; contradicting Colonel Wedgwood's assertion that passing the examination would cost £1,000, he said there were thousands of dental mechanics who were making provision to meet the examination. The adjournment motion was negatived.

On Clause 3, on the subsection as to the right of persons who had attained the age of 23 before the commencement of the Act to pass "the prescribed examination within ten years from that date," Colonel Wedgwood proposed to alter "the prescribed" to "a modified," his object being to help the dental mechanics. Sir Alfred Mond replied that "a modified" meant nothing, whereas the word "prescribed" meant that the examination was going to be specially prepared to meet the needs of the occasion. It would be prepared by the Dental Board; all the different kinds of dentists would be represented on the Board, and there would be other members as well. The amendment was negatived. Lieut.-Commander Kenworthy moved to omit the subsection in Clause 16 to apply the bill to Ireland, holding that for Ireland this was a domestic matter and might be left to Irish parliaments or "whatever they might end by having in that country." Sir Alfred Mond said that if Ireland did not want the benefit of this bill, he had no doubt that its people could get rid of it at some future date. If Ireland were excluded, a dentist practising there would be unable to come over and practise in England or Scotland. Asked what would happen to the American dentist, the Minister said that any American dentist holding degrees similar to an English dentist could of course practise in this country. The amendment was withdrawn.

On the motion for the third reading of the bill Colonel Wedgwood moved its rejection, as a protest against the way the matter had been approached that night. Members seemed to look at the measure, he said, as one merely affecting dentists and dental practitioners. The question, he submitted, should be whether there would be a better dental service, and whether too much would be paid for getting it. He was not certain that giving any body of people a close monopoly was likely to improve the work they did. A higher standard might be got by a stiff examination, but the cost of training might exclude a certain amount of intelligence in the country which might otherwise come into the service. The bill might raise the practice of dentistry, but the other side to the question was that it would raise prices. Every dental practitioner who got on the register would have to fall in with a scale of fees given to dentists on the register. Nearly every colliery village he knew had its dental practitioner. They did not do their work very well, but they were cheap. The Departmental Committee had tried to balance the coming advance in fees by recommending the establishment of a Public Dental Service; but that idea had not been taken in the bill. He regretted also the dropping of the Committee's proposal for scholarships. The part of the report which would raise the cost to the public had been adopted; the other two parts which

would have kept down the price and enabled the sons of working-class people to become dentists had been rejected.

Sir A. Mond, in reply, urged that the bill was for the benefit of the public. There was nothing new in principle in it. By amending the defect in the Act of 1878 they were endeavouring to bring dentistry, which was an important branch of medical science, up to a higher standard. To do this they were including a large number of men who had not the academic but the practical experience, and liberal provision was made for them. There was nothing in the bill to enable prices to be put up. The law of supply and demand would apply, and the consideration of means. If the bill had been to exclude a large portion of the men practising now and create a scarcity of dentists, there would have been force in Colonel Wedgwood's argument. But practically the same number of dentists would practise.

Mr. Radan supported the third reading. The proposals as to public dental service and scholarships could not properly be put in the bill as they were administrative matters.

Major Molson also declared himself in favour of the bill in the interests of the public, and remarked that the British Dental Association had behaved very generously in regard to the measure.

The bill was read a third time without division.

Bellahouston Hospital Inquiry.—Mr. Neil McLean, on June 9th, suggested to Mr. Macpherson that the inquiry into the administration of Bellahouston Hospital should be conducted in public. Mr. Macpherson said that, in response to a request for an impartial inquiry, he had appointed a Committee the members of which commanded the respect of all the people in Scotland. In the proceedings the medical sheets of the men might be asked for, and he could not be a party to the public disclosure of such information. Mr. McLean inquired whether the International Union of Ex-Service Men had been refused representation on the Advisory Committee. Mr. Macpherson said he had no information that this body was representative of ex-service men in Glasgow to any great extent. It had been requested to furnish a complete list of its members in Glasgow, but had not done so. He was satisfied that the interests of ex-service men were fully looked after by the twenty-six representatives already serving on the Advisory Committee. If, however, the International Union would satisfy the Regional Director in Scotland as to the strength of its membership, he would reconsider the matter. Mr. McLean submitted that the request for particulars was made on another occasion, and was also in the present instance out of all proportion to the purpose of the inquiry. Mr. Macpherson added that he thought he was entitled to ask the number of members of this union, as representation should be in proportion to membership. But he thought he had met Mr. McLean's point, as three of its members had been present throughout the inquiry.

National Insurance.—In reply to a question by Mr. Thomas Davies, on June 10th, as to an interpretation of a model rule defining the qualifying requirement for sickness or disablement benefit, Sir A. Mond said that under Section 14 (2) of the National Insurance Act, 1911, every approved society was required to have a rule as to the behaviour of members while incapable of work and in receipt of sickness or disablement benefit. The rule in question, which was drawn up with the concurrence of the Advisory Committee, composed of representatives of approved societies of all types, merely set out the restrictions which a society should impose on the activities of a member whom they had already decided to be incapable of work. The Ministry did not lay down any definition of light work, as it rested with each society to interpret its own rules in applying them to any case which might arise.

Discharged Soldiers and Insurance Benefit.—Mr. R. Young asked whether a discharged soldier temporarily unfit for work, and receiving while in hospital 100 per cent. allowance, was entitled to any benefit under the Insurance Act while in hospital. Mr. Parker, for the Ministry of Health, stated that sickness or disablement benefit was not payable to an insured person while he was an inmate of a hospital or similar institution, but the whole or part of the benefit was paid to his dependants, if any, or might be applied towards meeting any expenses for which the insured person might be liable, otherwise than to the hospital, or, with his consent, might be paid to the hospital if it was not maintained out of public funds. So far as the money was not used in any of these ways, it became payable to the insured person on leaving the hospital. Where the insured person was a discharged soldier in receipt of 100 per cent. allowance, the rate of sickness (or disablement) benefit was reduced by 7s. 6d. a week, unless he had been employed for 26 (or 104) weeks since discharge from the army.

London Hospital: the Closing of Wards.—Mr. Charles Edwards asked, on June 9th, whether the attention of the Minister of Health had been called to the closing of certain wards and curtailment of the out-patient department of the London Hospital, and whether he would take any steps to provide adequate facilities for medical treatment for the people of East London. Mr. Parker, for Sir A. Mond, said that no statement could be made until the Government had had the opportunity of considering the report of the I and Caves' committee which was appointed to inquire into the provision for emergency cases was made by the London Hospital and other infirmaries in East London.

Welsh Board of Health.—Sir A. Mond stated, on June 8th, in answer to Mr. A. T. Davies, that if a vacancy occurred he should be prepared to consider the appointment of a woman to the Welsh Board of Health. At present the Board, which consisted of salaried administrative officers, was sufficient in number for the work to be done.

Indian Army Officers' Pensions.—Colonel Sir C. Yate, on June 7th, asked whether a decision had been reached on the subject of the additional pensions of £100 and £200 a year which it was stated in the India Office Memorandum a year ago would be granted to Indian army officers on the superannuation list who had held high civil appointments. Mr. Montagu said he hoped to reach a decision shortly, whereupon Sir C. Yate pointed out the long interval since the first announcement.

Hospital Accommodation for Disabled Men.—Viscount Curzon asked, on June 9th, whether the Ministry of Pensions could take up some of the vacant wards in hospitals and so release hut accommodation, such as that at Ruskim Park. Mr. Macpherson replied that this hospital was transferred to the Ministry of Pensions by the War Office authorities. It had been fitted with special orthopaedic out-patient arrangements and special sections for the treatment of disabled officers and nurses. It had been found to provide the most convenient and incidentally the most economical centre for treating the large body of the disabled in that district.

NORTH EUROPEAN CONFERENCE ON VENEREAL DISEASES.

THE North European Red Cross Conference on Venereal Diseases, of which a preliminary note appeared in the *Journal of May 21st, 1921 (p. 749)*, was held from May 20th to 25th at Copenhagen. We have received from the National Council for Combating Venereal Diseases a copy of the following series of resolutions adopted by the Conference:

This Conference, having considered the general measures for the combating of venereal diseases which have been adopted by the participating countries, is unanimously of opinion, so far as the experience of the countries represented is concerned:

1. That the provision, by responsible health authorities, of adequate facilities for diagnosis and treatment on lines which ensure that the greatest possible number of infected persons is rendered non-infective, is a measure of prime importance to the reduction of venereal diseases. The urgent necessity of commencing treatment at the earliest possible moment should be emphasized. It is suggested that the above facilities should be provided free of cost to the patient where they are otherwise unlikely to be utilized to the fullest extent.
2. That the questions of compulsory notification and of compulsory treatment, being dependent on the experience, resources, and psychology of the people concerned in each country, must be decided by individual nations.
3. That instruction, theoretical and practical, in the recognition of venereal diseases, particularly in their earliest manifestations, and in their treatment, should form a part of the curriculum of every medical student, and that satisfaction of a test of proficiency in this subject should be a condition of every medical qualification.
4. That provision should be made at suitable treatment centres for such instruction of medical practitioners in the diagnosis and treatment of venereal diseases as will enable them to recognize these disabilities promptly and secure their adequate treatment.
5. That regulation and official toleration of professional prostitution has been found to be medically useless as a check on the spread of venereal diseases and may even prove positively harmful, tending as they do to give official sanction to a vicious traffic.
6. That the provision of "hostels" and rescue homes for the temporary care of girls suffering from venereal disease is a valuable means of preventing the spread of venereal diseases.
7. That the provision of opportunities for wholesome entertainment and recreation is an important factor in reducing the temptation to exposure to venereal infections.
8. That enlightenment of the general public on lines which are best calculated to minimize exposure to infection and emphasize the necessity of thorough treatment is an essential part of any scheme for the combating of venereal diseases. Instruction should particularly be addressed to parents and teachers in such a form as will enable them to give clear information on the reproduction of life and impress on adolescents the importance of individual responsibility to future generations. In the training of teachers special courses on these subjects should be provided.

England and Wales.

WELSH NATIONAL SCHOOL OF MEDICINE.

THE installation of H.R.H. The Prince of Wales as Chancellor of the University of Wales, at Cardiff, on June 8th, was an important event in the history of the Principality; later in the day the Chancellor laid the foundation stone of the department of Public Health and Preventive Medicine, to be erected at a cost of £50,000—the gift of Sir William James Thomas, to whose princely generosity the University already owed its Physiological Block, which was opened on the same occasion.

A number of honorary degrees were conferred by the Chancellor, amongst theipients being Lord Haldane and Mr. Arth The Prince delivered an admirable inaugural address as Chancellor, in the course of which he laid great emphasis upon the importance of laboratory accommodation and research work. There is a vast field for research in the important industrial area around Cardiff not only into the ordinary problems of disease, but into the health reactions of industrial life in the congested coal-mining districts of the Principality.

The Chair of Preventive Medicine at the Welsh National School of Medicine was endowed by the late Miss Emily Talbot of Margam Abbey, who transferred to the trustees of the college the sum of £37,000 in 4 per cent. Port Talbot Railway debenture stocks, the income of which is to be used for the salary of the Mansel Talbot Professor of Preventive Medicine. The University of Wales is fortunate in having secured the services of Professor Edgar L. Collis as the first occupant of this important department of its School of Medicine. The new Institute of Preventive Medicine as a component part of a complete medical school is remarkable as the first of its kind and far-reaching results are expected from this close association of the curative and preventive branches of medical research.

The new preventive medicine block will adjoin the recently erected physiological block as a part of the complete school of medicine, which is to be established on an island site which includes the old college—now used for the preliminary and intermediate stages of the medical curriculum. The buildings of the School of Medicine, when completed, will be an imposing series of structures in one of the main thoroughfares of the city, and close to the King Edward Hospital, which will provide the clinical facilities for the final studies.

A chair of tuberculosis has been endowed through the munificence of Major David Davies, M.P., and the Llandinam family, and by an arrangement with the Welsh National Memorial Association, Colonel S. Lyle Cummins, C.B., A.M.S., was recently appointed the first David Davies Professor of Tuberculosis.

The Dean of the Medical School, Professor David Hepburn, Professor Graham Brown—the Professor of Physiology—and Professors Collis and Cummins, were presented to the Prince, who afterwards inspected the physiological block with Professor Graham Brown, and showed a close interest in the equipment and research work of the department.

A great deal remains to be done before the scheme for a complete medical school is perfected, but, in the words of the address presented by the university authorities to the Chancellor, it is hoped that "the visit of the Prince will help the leaders of public opinion in South Wales to realize the significance of higher education in regard to national prosperity," and that the other captains of industry will follow the generous examples of the princely donors of the physiological and preventive medicine blocks, in the support of science as applied to the art of medicine and to industry.

A CRITICISM OF THE CHESHIRE TUBERCULOSIS SCHEME.

The tuberculosis scheme of the county of Cheshire has recently been the subject of criticism by the County Local Medical and Panel Committee.

The scheme is designed to provide facilities for treatment and prevention of all forms of tuberculosis affecting all classes of persons within the county, which, for administrative purposes, is divided into four dispensary districts, with one subdistrict. In each of these one or

more dispensaries or branch is established; at present fourteen such have been set up. The scheme also proposes to provide sanatorium accommodation for early curable cases and pulmonary hospitals for advanced cases. A sanatorium is now being established at Burntwood to provide seventy beds. It will serve the whole county of Cheshire, including the county boroughs, and also the county borough of Stoke-on-Trent, which is in Staffordshire, as is in fact Burntwood itself. There is also now approaching completion a training or employment colony at Wrenbury. The Cheshire branch of the British Red Cross Society and Order of St. John gave £30,000 to the County Council to help in establishing a colony for fifty cured or arrested male cases. Wrenbury Hall, with 162 acres, was purchased for the purpose. The doctor and matron are already installed, and it is hoped that the place may be opened in a few weeks.

Pulmonary hospitals for advanced cases requiring treatment or isolation are provided in tuberculosis pavilions attached to some of the ordinary isolation hospitals of different Cheshire districts. Arrangements have been made with the general hospitals, infirmaries, and cottage hospitals to provide beds for emergency cases and for surgical cases. Additional beds are retained at the Leasowe Children's Hospital for children affected with non-pulmonary tuberculosis, and the Royal Liverpool Country Hospital at Heswall is also used for the same class of disease. A central laboratory for the examination of sputum and pathological specimens has been equipped in connexion with the central office of the county tuberculosis officer. In addition to this officer the staff consists of four whole-time tuberculosis officers and eight tuberculosis nurses, two in each district working under the direction and supervision of the district tuberculosis officer. In the fifth, the Chester district, arrangements were made to share the services of the city tuberculosis officer, while in the part of the Chester area formed into a subdistrict the duties of the tuberculosis officer are carried out by a part-time officer, who is also Medical Officer of Health for the North-West Cheshire Combined Sanitary District. The chief tuberculosis officer was appointed to act as consultant to the district tuberculosis officers and to practitioners where necessary, and generally to supervise the residential treatment of all cases in institutions. As has already been stated, fourteen dispensaries and branch dispensaries have been established. The work done at a dispensary is defined as follows:

"The function of the dispensary is to act as a receiving centre for all classes of cases, and all kinds of information relative to and affecting tuberculosis in the district; a centre to which cases shall be sent for expert examination and diagnosis; a clearing house where all cases of tuberculosis shall be sorted out, classified, and suitable treatment or procedure determined in each instance; old cases re-examined from time to time as may be necessary, and home treatment supervised."

"Each dispensary district constitutes a complete unit of organization, and is under the control of the district tuberculosis officer, the nurses acting directly under his supervision. The tuberculosis officer examines patients at the dispensaries, makes such recommendations and reports as may be necessary in each case, and also acts as a consultant to the medical practitioners in regard to all cases of tuberculosis occurring within his area."

"One of the important functions of the dispensary is the examination of 'contacts' with a view to detection of incipient cases of disease at the earliest opportunity and before symptoms have become manifest."

The scheme, we understand, was promulgated in 1915, but for various reasons is only now coming into full working order. It has been watched by general practitioners in the county with interest from the first, and recent developments have induced the Cheshire Local Medical and Panel Committee to address a letter to the Cheshire County Council, suggesting that the tuberculosis dispensaries should be done away with and a simpler, more efficient, and less expensive system substituted.

The letter states that nine-tenths of the matters in question are within the day-to-day experience of general practitioners, who are naturally keen but far from unfriendly critics of the new official measures. The letter goes on to point out that the Committee regards the sanatorium at Burntwood as the central feature of the scheme. The sanatorium and the tuberculosis pavilions attached to certain of the isolation hospitals should have observation beds, to which a person, when his illness was first notified, would be admitted. The case could

there be investigated far more thoroughly than at a dispensary consultation; a temperature chart would, for example, be available, and after a few days, or in some cases weeks, no doubt would remain as to the condition of the patient and the tendency of the disease in his case.

With regard to the proposed consultative function of the dispensaries, the Committee expresses the view that consultations should be with consultants, and that in difficult cases the services of physicians, and in cases of surgical tuberculosis those of surgeons, of hospital standing should be available. The letter continues:

"The dispensaries can never provide a satisfactory consultant service. You cannot attract men of matured hospital experience and standing for the salary that can be offered. You cannot 'grow' such experience in an atmosphere in which the clinical element is too rarefied and the administrative too toxic. It is a product of the hospital. True, individuals may transcend their opportunities; but then the higher paid berths elsewhere soon attract them.

"On the other hand, my Committee holds that the senior medical staff at Burntwood, and also at Wrenbury, should be available for consultation, and that the assistant tuberculosis officers should be transferred to the sanatorium staff on the closure of the dispensaries. The Burntwood staff might possibly have to be increased by an extra doctor if the demand for consultants were to grow."

"The monotony of the life of an isolated institution, the tendency to stagnation, and the lack of stimulus from outside association would all be usefully modified by adding the duties of consultant to those of sanatorium medical officers. Alertness, efficiency, knowledge of the districts from which the patients come, their environment, and status will be gained on the one side; on the other, general practitioners will be brought into useful touch with the work at Burntwood."

The examination of contacts, it is considered, would be more likely to be acceptable if done by the family doctor.

"In the long run," it is said, "that system will prove to give more complete results than the vain attempt to carry out a family inquisition through the dispensary. If there were 500 families to be examined a year, at a guinea a family, the expense would be small compared with the saving of the rents of the dispensaries and of salaries."

On sanitary supervision and the enlistment of voluntary aid the letter makes the following observations:

"Since the inception of the scheme the district medical officer of health and sanitary inspector have regarded the matter of tuberculosis as very largely taken out of their hands; and there has been a tendency for the care of the sanitary environment of a tuberculosis patient to fall between two stools. The information that the Local Health Authority was once again to regard itself as fully responsible for the background in which the life of a consumptive is to be led would reawaken it to its opportunities, and bring into play all the forces of local knowledge and local enthusiasm."

The conclusion is that the dispensary system while it may work well in a city is inappropriate to a great scattered county, and the hope is expressed that the county council, with the advice of its chief tuberculosis officer, whose courtesy and desire to help is acknowledged, will accept the expression of the views of general practitioners contained in the letter. Their proposals, it is pointed out, have at least the merit of being far less expensive than the scheme that holds the field.

LIVERPOOL MEDICAL INSTITUTION: THREE JUBILEES.

A special general meeting of members was held on June 8th, to which ladies were invited, to tender the congratulations of the Institution to Drs. W. Macfie Campbell and John B. Edis and Mr. Rushton Parker on attaining the jubilee year of their membership. Dr. John E. Gemmell (President) was in the chair, and there was a good attendance of medical men and ladies. Owing to indisposition, neither Dr. Campbell nor Dr. Edis was able to be present. At the instance of the Chairman, the resolution that the congratulations of the Institution be tendered to each of the members was proposed and seconded formally by life-long friends of the recipients of the honour. In the case of Dr. W. Macfie Campbell, the resolution was proposed by Dr. T. R. Glynn, ex-President, who called to mind that Dr. Campbell was at one time resident house-surgeon at the Northern Hospital when Dr. Glynn was honorary physician. Afterwards he became leading obstetrician. Dr. Campbell had filled all the posts in the Medical Institution and was an ex-President. In spite of a large practice, his zeal in promoting the interests of the profession was remarkable, and Dr. Glynn expressed the hope

that Dr. Macfie Campbell would still enjoy good health, to which he was glad he was now returning, for many years to come. Mr. Charles H. B. Shears, in seconding the resolution, mentioned that he had been house surgeon at the Northern Hospital under Dr. W. Macfie Campbell, and bore testimony to the kindness and sterling character of his old and respected friend. The President read a letter from a member, who preferred to be anonymous, extolling the high professional standing Dr. Macfie Campbell always took in his relation to his fellow practitioners. A letter from Dr. Macfie Campbell was read by the President, in which he expressed his great regret at not being present to receive the congratulations of the members which he so highly appreciated and for which he tendered his sincere thanks. Dr. Macfie Campbell called to mind events in the history of the Liverpool Medical Institution, and mentioned the circumstances in which the first lady—the late Dr. Lucy Craddock—was admitted a member. The resolution was carried unanimously.

Dr. Charles B. Macalister proposed the resolution of congratulations to Dr. John B. Edis. He came to Liverpool to hold the post of medical missionary, and did much work during the epidemic of typhus raging at that time. Although not a robust man, he not only survived an attack of typhus and of typhoid fever, but built up for himself a large midwifery practice, and had brought into the world some ten thousand babies. He was one of the medical officers attached to the Hospital for Diseases of Women, and during a long and strenuous life continued to take a keen interest in the Liverpool Medical Mission. He was a great cyclist and expert with the camera, and to these recreations he ascribed his good health. Mr. Keith W. Monsarrat seconded the resolution, adding that Dr. Edis was a man held in affectionate regard by all with whom he was brought into contact. The Chairman put the resolution to the meeting, which carried it unanimously.

In proposing the resolution of congratulations to Mr. Rushton Parker, who was present, Mr. Paul gave an interesting account of his earliest recollections of Mr. Parker, whom he first met in 1875. Pathology, then comparatively a young science, was the bond of union between them. Mr. Parker was essentially a scientific surgeon, and this habit of mind was his leading characteristic. Mr. Parker recognized at the very outset the genius of the late Hugh Owen Thomas, and was one of the first in Liverpool to introduce the famous surgeon's methods into his own practice. Mr. Parker was ever sincere, frank and outspoken, witty, and possessed of a keen sense of the foibles of his professional brethren. Mr. Paul felt it an honour to be the proposer of these congratulations, and expressed the hope that Mr. Parker might celebrate his diamond jubilee membership. Dr. Glynn seconded the resolution, emphasizing the characteristic love of truth ever to be found in Mr. Rushton Parker, and incidentally alluded to the many acts of kindness he had shown to many of his professional brethren. Mr. Newbolt supported the resolution, adding an expression of his personal regard for Mr. Parker, not only as a surgeon but as a straightforward fearless man. The motion, on being put from the chair, was carried unanimously, and amid applause Mr. Rushton Parker rose to reply. He expressed his appreciation of the high compliment that the Institution had paid him, and went on to describe his earliest experiences, amusingly sketched incidents that happened to him as a young surgeon, and delighted his hearers with reminiscences of Mr. Stubbs, one of the honorary surgeons to the Royal Infirmary at that time. Mr. Parker alluded to the origin and the growth of the Liverpool Royal Infirmary School of Medicine, now the Medical Faculty of the University of Liverpool, and mentioned some of the characteristics of the lecturers of that time. In thanking the members for their congratulations, he felt he ought to propose a resolution of sympathy with Dr. Macfie Campbell and Dr. John B. Edis for their inability to be present on this occasion, and to express the hope that both would soon recover from their indisposition.

LIVERPOOL CHAIR OF OBSTETRICS.

At a meeting of the Council of the University of Liverpool, held on June 8th, Dr. W. Blair Bell, gynaecological and obstetrical surgeon to the Royal Infirmary, Liverpool, and lecturer in clinical gynaecology in the university, was appointed to the Chair of Obstetrics and Gynaecology, vacant through the resignation of Professor Henry Brigt-

THE LEEDS GENERAL INFIRMARY: RE-ALLOCATION
OF BEDS.

The question of the re-allocation of beds throughout the hospital was recently referred to the Faculty for consideration and report, and, although this was by common consent regarded as a highly contentious matter, careful consideration in a spirit of mutual concession has resulted in the presentation to the board of a report which had the merit of coming from the Faculty without a dissentient and which was adopted. It is true that effect cannot be given to the re-allocation until the modernization of certain of the wards, which was referred to in this column, has been completed. During the years of the war the division of the beds between the various departments has been modified and obscured by many circumstances. Thus, on the outbreak of the struggle a request came from the War Office for accommodation for 115 wounded soldiers, and this was afterwards increased to 135. A ward which is usually kept as an emergency ward was at once put in commission and the large out-patient waiting hall was converted and used for the accommodation of patients, much of the out-patient work being relegated to temporary centres near the infirmary. In passing, it may be mentioned that 4,918 soldiers from convoys were dealt with in the infirmary, and in this way the pressure on the Second Northern General Hospital was lessened. The admission of soldiers came to an end during 1919, but beginning in 1918 and continuing in 1919 there has been a yearly admission of ... who are being sent by some one or other of the authorities acting under the Ministry of Pensions. The figures for 1918, 1919, and 1920 were respectively 346, 353, and 283, and it is hoped that the numbers will dwindle and this call on the infirmary soon disappear, except possibly for a small number of special cases sent for investigation. The buildings of the Second Northern General Hospital are being used for pensioners, and this would appear to make further demands on the infirmary unnecessary, except, perhaps, for very special cases. During the war, also, it was found necessary to close two wards owing to a scarcity of nurses, so that when the new pavilion of the King Edward Memorial wing was opened the number of beds, as compared with pre-war years, was not materially increased. When the wards which it is determined are to be used in the not remote future can be occupied, there will be 432 beds for adults and 99 cots for children, with, in the case of the latter, the prospect of a substantial increase in the form of a semi-open-air ward on the terrace with accommodation for about 20 children. The arrangement of the wards has made it possible to allocate these beds and cots as follows:

	Beds.		Cots.	Total.
	Male.	Female.		
Medical	65	47	33	145
Surgical	135	71	52	258
Ophthalmic	27	17	8	52
Aural	14	12	6	32
Gynaecological	—	23	—	23
Isolation	8	8	—	16
Suspected alcoholism	2	—	—	2
Observation	2	—	—	2

Until such time as provision can be made for those patients who are at present accommodated in the isolation wards it will not be possible to transfer the isolation block to the venereal department, which is regarded as desirable, and which has been decided upon. This re-allocation of beds and cots, which has been the subject of much thought, does away with the mixture of medical and surgical cases in children which prevailed to a certain extent under the old arrangements; it brings the surgical cases nearer to the operating theatres, and leads generally to concentration of charges and convenience of teaching. It is hoped that the scheme will be in full operation by the beginning of next year.

PROVISION FOR TREATMENT OF CHILDREN IN LEEDS.

In the re-allocation of beds and cots above referred to, the need for improved and extended accommodation for children has been kept steadily in mind. It is indeed true that the number of children treated both in the in-patient and the out-patient department of the infirmary is greater than many members of the Leeds public grasp. This it is which leads from time to time to expressions of regret that "there is no children's hospital in Leeds." As a matter of fact no fewer than 1,500 were admitted to the children's wards during the year 1920, and the numbers dealt with in the out-patient department are very great. Until lately the accommodation especially reserved for children has been only 71 cots. In the near future, as has been mentioned above, the number of cots will be increased to 99 with the prospect of some 20 more in the semi-open-air ward, and such a segregation of the children's cots will be secured that the infirmary may be regarded as containing within its walls a fully equipped children's hospital. It is true that there is still in Leeds, appreciable by those who have eyes to see, ears to hear, and hearts to understand, an eloquent and urgent appeal for more accommodation for the treatment of children; but those who are best informed will cordially agree with Mr. Charles Lupton, the treasurer of the infirmary, when he says that the wisest way to meet this is not the provision of a new hospital, but a generous extension of the accommodation, some miles away from the centre of Leeds, for the treatment of those cases which are necessarily of long duration, such as articular and abdominal tuberculosis, and heart disease at that stage in its development when a few months of care may improve the prospect of a useful life and may lessen the likelihood of much suffering. An expensive and highly specialized institution is, indeed, in the first instance necessary for the treatment of such cases as may require difficult operations and careful investigation; when this time has been tided over the patients can be transferred to a place where they can get those things which are their later necessity—namely, good food, fresh air, and kindness. Leeds has been happy in the centralization of its medical charities; it is to be hoped that this will not be disturbed; decentralization would lead to extravagance in management, and it would be bad for the welfare of the patients and injurious to the teaching of the students. Those, therefore, who desire to further the treatment of children in Leeds can best do so by subscribing to the funds of the infirmary, and especially by the endowment of cots. In this respect the Leeds Caledonian Society has set a good example: at its annual dinner last January Dr. T. Wardrop Griffith, the president, was able to hand to Mr. Charles Lupton a cheque for £1,200, which he hoped might in time be increased to £1,500, to enable three cots to be endowed; it was, he said, the result of a collection made among the members of the society.

Scotland.

MEDICAL ADVISER TO PRISON COMMISSIONERS.

The Secretary for Scotland has appointed Harry Rainy, M.D., F.R.C.P.E., Vice-President of the Royal College of Physicians of Edinburgh, to be Medical Adviser to the Prison Commissioners for Scotland, in succession to the late Sir Thomas R. Fraser.

GLASGOW EAR, NOSE, AND THROAT HOSPITAL.

At the annual meeting of the Glasgow Hospital for Diseases of the Ear, Nose, and Throat, which was held on June 8th, Lord Provost Paxton presided and moved approval of the directors' report. In this it was stated that during the past year steps had been taken to organize a committee and to raise funds for the proposed new hospital, and that Lord Weir would act as chairman of this committee. It was hoped that the response to the appeal for funds which was now being made would enable the directors to build the new hospital within the next two years, as at present the accommodation available was greatly overtaxed. Last year 6,008 patients were treated at the hospital, and the number of attendances was 20,339. The building fund now amounts to £11,650.

Correspondence.

THE PURE CLINICIAN.

SIR,—I have read with interest but great uneasiness Sir James Mackenzie's address at St. Mary's Hospital; with uneasiness, for am I not right in assuming that Sir James is leading a new movement which appears to be increasing the distance between the patient and the laboratory, instead of striving for what everyone who has the interests of prevention, early diagnosis, and accurate specific treatment at heart desires—a decrease in the distance until there is a complete liaison?

He states that the diagnosis and prevention of typhoid fever, syphilis, and rabies is entirely the result of accurate clinical observation, while such diseases as malaria had to be handed over to the laboratory worker; yet everyone knows that the accurate diagnosis of all these diseases and their prevention cannot be achieved in the absence of the laboratory. The treatment of syphilis has to be controlled by laboratory tests, that of rabies is entirely dependent on the laboratory, while the treatment of the enterics, which can be aborted or very rapidly cured by laboratory products if the laboratory is properly used for early diagnosis, has, in the hands of the pure clinician, made no advance in specific treatment in the last fifty years.

I quite agree with Sir James as to the importance of prognosis. I always teach the importance of this and urge the perusal of the Registrar-General's returns, for it is from these and these alone that prognosis can properly be judged. Sir James takes measles as an instance for prognosis in cases of antigen (vaccine) therapy. Unfortunately the laboratory has so far failed to diagnose this disease, but measles, as Sir James points out, is of little importance; it has little effect on the general death rate. Let me take, however, two diseases, in one of which—tuberculosis—I am especially interested, and the other—heart disease—in which he is.

Now anyone reading such a book as Riviere's *Early Diagnosis of Tuberculosis of the Lungs* will realize to what very great refinement the interpretation of symptoms produced by the excitation of abnormal and interference with normal reflexes and that of physical signs has reached, and yet by these methods no certain diagnosis can be made, for the enlarged glands at the hilus of the lungs can be produced by many other microbes besides the tubercle bacillus. Only by subcutaneous tuberculin tests, a product of the laboratory, can an accurate diagnosis be made at this stage. Sir James Mackenzie's life work has been the accurate diagnosis of the lesions in hearts damaged by the depredations of microbes, but I have not gathered from his writings that he has been particularly interested in the accurate diagnosis of the microbial cause of the symptoms he has been treating; and yet the prevention of heart disease or of the constant flares-up of infection when it has occurred is entirely dependent on the isolation of the causative organism and the immunization of the patient with it.

The failure to control these and other causes of the highest death rates has been due to the seeking for and cure of the symptoms of the diseases instead of the seeking for and destruction of the microbial causes of them. For this there is no excuse, for the laboratory has made known the causes and furnished us with the means of treatment.—I am, etc.,

Dublin, June 4th.

W. M. CROFTON.

DEFECTS IN TUBERCULOSIS ADMINISTRATION.

SIR,—Efforts have been made in the county of Essex to remove the confusion and friction referred to by "Mixture" in your issue of June 4th (p. 839).

Conferences with the Ministry of Health and local sanitary authorities resulted in the unanimous adoption of the principle of a combined medical service for a specified area, whereby a whole time medical officer was appointed to undertake the duties of local medical officer of health and assistant county medical officer (including tuberculosis officer, school medical inspector, and inspector of midwives). Salary and expenses are apportioned between the county council and the local sanitary authority on an agreed basis. As local medical officer of health he is directly responsible to the local sanitary authority, and

as assistant county medical officer he reports to the county council, through the county medical officer. There are already three such appointments, the first officer having actually taken up duty on April 1st, 1920.

Essex claims to be the pioneer of this fusion of local health duties, and it has succeeded beyond all expectations in removing hindrances to progressive preventive and remedial work. There is no overlapping or friction, one medical officer being responsible for safeguarding the health interests, personal as well as environmental, of the community. He receives his own notifications of cases of tuberculosis, keeps his own register, acts upon the cases as tuberculosis officer as well as local medical officer of health, and is further supported by a combined nursing and clinic service built up on the same lines. The same remarks apply to the school medical service.

Briefly, it may be said that unification has brought about a more economical service, increased the efficiency, zeal, and interest of the medical officer, and reduced the number of officials who visit homes by establishing a central health officer. The scheme is now about to be established on a somewhat similar basis in six more sanitary districts with an acreage of 203,934.

In other parts of the county we have endeavoured to overcome the difficulties in regard to the record-keeping and following up of notifications of cases of tuberculosis by asking the local authority to appoint the county council's tuberculosis officer as assistant medical officer of health, but this was secured in only three instances.

I am more than ever satisfied, after twelve months' experience, that the combined scheme outlined above is a foundation on which can be built an efficient and co-ordinated health service in county districts.—I am, etc.,

W. A. BULLOUGH,
County Medical Officer.

Chelmsford, June 11th.

A NEW STUDY OF APHASIA.

SIR,—One or two passages in your important discussion of this subject, no less than one or two passages in the lectures referred to therein, are perhaps a little difficult to some of us.

It is not quite clear what is meant by the "materialism" of the schoolmen which is said to have been swept away by Descartes, or how it is that, as a result of the teaching of Descartes, no one "presumed to correlate directly the activities of the Mind with the life of the brain."

For, in the fifth part of the *Discours*, Descartes himself discusses:

"Quels changements se doivent faire dans le cerveau pour causer la veille, et le sommeil et les songes; comment la lumière, les sons, les odeurs, les goûts, la chaleur et toutes les autres qualités des objets extérieurs y peuvent imprimer diverses idées par l'entremise des sens; comment le foin, la soif et les autres passions intérieures y peuvent aussi envoyer les leurs. . . ."

Descartes goes on clearly to indicate how, on the side of cerebral outgoings, movements of the limbs are produced. Even when he pictures animals as differing from human beings in the absence of controlling and directing faculties, he does not hesitate to correlate human reason with the life of the brain, in the famous passage which, though usually quoted as locating the "soul" in the pineal gland, really anticipates what we now express when we correlate so much of our emotional life with states of the chromaffin system.

Again, the view of language attributed by you to Locke is really that of Descartes. For the latter, speaking of animals as automata, says:

"Jamais elles ne pourraient user de paroles ni d'autres signes en les composant comme nous faisons pour déclarer aux autres nos pensées."

Here is the idea of language as expressive of propositions, and the famous sentence which Talleyrand inverted to form his wicked but obvious epigram.—I am, etc.,

London, W., June 10th.

F. G. CROOKSHANK.

THE PREPARATION OF SCIENTIFIC PAPERS.

SIR,—As Sir James Barr is so gracious as to express, in repeated phrases, his gratitude for my "instructional criticism," I may well be content to leave a decision on any disputed points to the judgement of your readers. Sir James states a limited defence with, if I may say so, excellent temper, and he attempts some amusing though

irrelevant counter-strokes; where, even to his ingenuity, defence is frankly impossible, he, as a prudent controversialist, practises a judicious silence. Had he cultivated the "pool" which he commends to me he might perchance have avoided his blunder relative to the "tower." But here again he shows his disposition to preach rather than to practise. His imagination and good nature credit me with a resolve not expressed in my letter, but if he, too, "intends to get rid of all superfluities," our combined examples will surely not be in vain. It is here that his collection of "a variety of paper fasteners" gives me some concern; so formidable an apparatus suggests a provision for the development of a "verbosity" from which Sir James fondly believes himself at present to be free. He offers me a specimen "fastener," but I would much rather hear he had "scrapped the lot." His opportunity just now would seem to lie in "works" rather than in "words," for after his recent enterprise it is to be feared he will, at least for some time, be ineffective in the pulpit.—I am, etc.,

London, W.1, June 13th.

C. O. HAWTHORNE.

REFRACTION WORK IN CHILDREN.

SIR,—When I was a house-surgeon in an eye hospital I was taught that retinoscopy was an exact science, that there should be no obstacle in determining objectively the actual error of refraction in the eye, and that the difficulty in prescribing glasses lay in deciding which glass was most suitable to the individual needs of the patient. In solving this difficulty in children one relied more on objective than subjective findings, entirely so in the case of illiterates.

Dr. A. E. Larking states that he considers three cases an hour a good average, but continues to the effect that six or more could be done were subjective tests dispensed with. It follows that at least half the time employed over the three cases an hour would be spent on subjective examination. What additional information would these subjective tests yield to aid in arriving at the desired glass? As accommodation has been paralysed, the glass giving the best vision would almost invariably be that which gives full correction. The refractionist by his retinoscopy is already aware of the strength of this lens, so that beyond the vision obtained he has learned nothing fresh. This glass, while giving the best vision, is not necessarily the one to be prescribed.

Again, in the very common error of hypermetropia with or without astigmatism, how is the examiner to estimate the presence or amount of latent hypermetropia, the ciliary muscle being paralysed, without knowledge of the manifest hypermetropia obtained only by a subjective examination made before atropine has been used? Is it wiser to lend a patient ear to the lisping assistance of childhood than to rely upon one's own observations and judgement backed by rules proved by experience to be sound, such as full correction in concomitant strabismus, in low and moderate degrees of astigmatism, in low and moderate degrees of myopia, and the use of Mr. Bishop Harman's chart giving the average necessary correction deduced from the total hypermetropia obtained by retinoscopy?

I have no desire to depreciate the importance of subjective examination, but feel convinced that if one is inclined to give it that prominence which Dr. A. E. Larking appears to regard as its due, it would be more helpful if deferred until the action of atropine had passed off.

Mr. J. Parkinson Higham raises the question of sweated labour, I think pertinently. It would be interesting to learn how many hours at six refractions an hour—that is, how many refractions a day—were expected of Dr. A. E. Larking by the Education Committee he mentions.—I am, etc.,

Barra, N.B., June 2nd.

J. N. M. SUTHERLAND.

SIR,—The emphasis laid on speed in refraction work in children will, I am afraid, tempt many men, especially beginners, to spend less time on their cases. This would be a great misfortune.

A case, without astigmatism, takes but a few minutes, but a beginner will find it very difficult to determine that no astigmatism is present, and should spend time on the point. In severe astigmatic cases, any time up to, say, three-quarters of an hour (beginners more) can often be

spent with advantage. It is wonderful what a small change, say, in the axis of a cylinder, will sometimes effect. Until all such possible changes have been tried, the best possible has not been done. Subjective tests are of great value not only in adults, but in children, and, within the above time limits, it would be true to say that the longer the time spent the better the result, and that more time had better be spent than other than the best possible result obtained.

Any number of cases can be done in an hour. The number actually done will depend on the degree of accuracy attained, the skill of the surgeon, the cases waiting, and most particularly on the proportion of severe cases. In our central eye clinic weeks sometimes pass without a case free from astigmatism, and, after having done some 7,000 refractions, I find time well spent at about three cases an hour.

To illustrate the importance of the best possible, perhaps I may be pardoned for giving this instance: A youth was brought to me privately, wearing glasses prescribed, possibly in a hurry, by a public institution. He stated that he had just been dismissed from work owing to his defective sight. A full hour spent on the case—one of severe myopic astigmatism—resulted in new glasses giving a considerable improvement, and a letter to his employer in a conditional reinstatement. He now, a year later, reports that he has retained his post.

Accuracy spells efficiency, comfort, first cost of glasses last cost; and, as bad spelling is now known to be often due to uncertain memory pictures the result of defective sight, accuracy spells spelling.—I am, etc.,

RALPH HOPTON, M.D. Lond.,

Oculist to the Leeds Education Authority;
Eye Surgeon to the Blind School.

Leeds, June 5th.

THE PREVENTION OF PUERPERAL INFECTION.

SIR,—For many years I have read with interest various articles on puerperal sepsis. All the authors advise the use of gloves, yet I have nowhere seen stated how long they should be boiled. Upon the details of the process employed rests the success or otherwise of this method. Unless the most scrupulous care be taken the chances of failure are considerable. For nearly ten years I have never made an examination without using a sterilized glove. The method I adopt is as follows:

On entering the house I ask for a saucepan with lid, a clean pocket-handkerchief, and boiling water, and that the gas stove be started. The glove or gloves (it is better to sterilize two or more at the same time) are each rolled up in a handkerchief beginning at the fingers, first having had at least an ounce of boiling water poured inside to wet all the fingers. They are placed in the pan and boiling water is poured over them, sufficient to boil for fifteen minutes without being dried up. A 4 oz. ear syringe is filled with hot water and also put in the pan. The lid is placed on, and I wait until I am sure all is at boiling point and boil for fifteen minutes. It is necessary to tell the people on no account to interfere with the boiling process.

In the meantime I commence cleansing my hands, continue this for five minutes, then go and see the patient, then resume cleansing the hands, telling the attendant with clean hands to give the patient a good wash with soap and water. It is no use in an ordinary case to suggest shaving the parts. Even the cutting off of extra long hair is resented.

At the end of fifteen minutes the lid is removed and the whole sufficiently cooled with ordinary tap water. The folded handkerchief and the syringe are removed to a basin of 1 in 1,000 biniodide. The vulva is separated by pulling on the neighbouring skin and washed by a stream of antiseptic by means of the syringe. The glove is now unrolled in the solution and the wrist picked up (allowing plenty of solution to float inside) and drawn on the hand to be used. It is assumed that the glove has been made right or left as the case may be, at the beginning. The examination is now made, using no lubricant. It is sometimes a little difficult, but a gentle rotary motion of the hand will overcome this. At the conclusion of the examination the glove is taken off and not used again.

I consider that two things are of the utmost importance. The glove must be sterilized on the spot, and it must be rejected after the examination, and a fresh one used if further interference is necessary. Of course, when forceps

are used, all are boiled together, but even then I roll up the glove.

Unless practitioners are prepared to take similar care in the use of gloves, it will be, in my opinion, much better to trust to the hands.—I am, etc.,

June 3rd.

OPOLONAX.

SIR,—In the articles and letters on puerperal infection two points of interest have received insufficient attention. In the first place, how far is puerperal septicaemia due to the fact that a small proportion of patients have not the ordinary immunity to the risks of infection. The absence of this immunity rather than the presence of any special form of infection may be responsible for a large proportion of the cases of septicaemia. We have all seen cases in ordinary practice in which a simple superficial infection by a common organism (such as the *Staphylococcus aureus*), in the form of a small boil, has proved fatal owing to the want of power to acquire immunity. I do not recollect any report of an investigation of the discharge from the anterior vagina taken day by day for the first week after a normal confinement, but in appearance and colour such discharge suggests organism infection in many patients who show no evidence of toxæmia.

Secondly, have we considered the point of view of the patient herself? In most women a confinement is one of the outstanding incidents of her life and largely a subject of conversation with her friends; the medical attendant who can give her a good hope of freedom from severe pain during that time, without unusual risk, is gratefully thought of. Delivery under anaesthesia is generally indefinitely delayed without instrumental help. To what extent is it proved that septicaemia is increased by such methods? It is of some value to the State for a patient to say that a confinement is "not so bad after all," and that she will not fear to run a similar risk again, as against instances where a woman says that her experience of her first confinement was sufficient to make her prevent a similar occurrence for many years. We cannot ignore altogether the patient's point of view, and an explanation of the risk of sepsis is poor consolation to a woman in a long second stage of a first labour.—I am, etc.,

June 6th.

H. S.

SIR,—When bits of placenta, membranes, blood clots, or other dead animal matter remain in the uterus for a little time after parturition they will usually become infected with dangerous bacteria, and puerperal fever will be likely to result. One of the first points therefore in preventing puerperal infection is to prevent, as far as possible, the retention of putrescible material in the uterus. I have seen a case where death resulted from a tiny and hardly visible shred of dead tissue adherent to the interior of the uterus, a small abscess resulting opposite it on the exterior surface of the uterus. This abscess opened by a pin-hole opening into the peritoneal cavity, and death resulted. The presence of such shreds cannot readily be suspected or avoided without precautions not often adopted and not to be recommended as routine measures. If, however, a patient suddenly develops rigors and the temperature begins to rise, there is not a moment to be lost. The interior of the uterus should, in my opinion, at once be thoroughly swabbed or scrubbed out with a strong undiluted antiseptic by means of cotton-wool wrapped firmly on a strong uterine probe or sound. I have known this treatment stop at the commencement what seemed certain to be a virulent puerperal fever. In a few hours it will often be too late. The infective material must be removed or rendered harmless before the infection has spread beyond control.—I am, etc.,

June 3rd.

M. A. O.

THE ORGANIZATION OF SCHOOL OPHTHALMIC WORK.

SIR,—Mr. Bishop Harman states that "at present infants under the age of 7 years attending school do not have their eyes examined." Doubtless this is true of many educational areas, but I should like to point out that in the schools administered by the School Board of Glasgow the children in the infant departments have been regularly examined by the visiting oculist since 1905.

The examination is by retinoscopy and is rapidly done with the aid of a skiascope, which I described in the *Ophthalmic Review*, July, 1905. The children are brought into the dark room by classes, and are entirely under the control of their teachers, one of whom attracts the attention of each individual child while under examination. The co-operation of the teachers is essential, but in an experience extending over many years I rarely failed to obtain this, and I think the main reasons were that (a) the results of the examination were often of practical interest to them, and (b) they themselves realized that only with their help could the examination be carried out in a reasonable time.

Mr. Harman indicates the desirability of a routine examination of the eyes of infants, and the object of my letter is to show that such an examination is not only practicable but is an established custom here in Glasgow.

Further, I should like to add that the subjective testing of the older children is done entirely by the teachers.—I am, etc.,

Glasgow, May 27th.

H. WRIGHT THOMSON.

SIR,—Until the organization of school ophthalmic work is put on a better footing there is not likely to be more men seeking qualifications for doing this special work. For the majority it would be throwing time and money away. I know a man who has given four years to work in one of the London ophthalmic hospitals, and as clinical assistant in the eye department of one of the large general hospitals, ultimately becoming the senior clinical assistant. Nearly two years since he was appointed by a county council to do this special work, but during that time he has been favoured with one case only; there have been some 600 in all (it is not possible to find out the exact number); these have been examined and the fees taken by the assistant school inspector and his partner. I make no charge of unfairness or greed, I only mention the fact which speaks for itself, and I shall be pleased to communicate with Mr. Harman if he wishes to verify the statement. But whilst human nature remains what it is, I quite agree with him when he says, "there are advantages in separating the work of school medical inspector from the treatment of children found to be defective." At any rate, this kind of thing should be made impossible in a liberal profession, and until it is, it is no use asking medical men to give up time to acquire this special knowledge.—I am, etc.,

May 31st.

PAX.

COCYGEAL FISTULAE.

SIR,—Mr. Lockhart-Mummery, in your issue of June 4th, expresses the opinion that all fistulae met with in the neighbourhood of the tip of the coccyx, which do not communicate with the rectum, are congenital in origin. This is scarcely correct, because I have notes of a case of coccygeal fistula which was the result of necrosis of the coccyx. Also there is a type of fistula, having no communication with the rectum, which is the result of suppuration of the presacral lymphatic glands. The abscess thus formed, being bounded behind by the sacrum, and in front by the fascia propria of the rectum, has no alternative but to find an exit through the skin between the anus and the tip of the coccyx. Sometimes there is a single opening on one side of the middle line, but often there is a second opening on the opposite side, the result being a vertical horseshoe fistula. There is no doubt, however, that fistulae of congenital origin occur in this locality, but they are extremely rare. Although such a fistula may not make its appearance until comparatively late in life, in all cases it has been preceded either by a tumour or by a post-anal dimple.

Bland-Sutton, to whom, as Mr. Lockhart-Mummery says, we owe our knowledge of the origin of this type of fistula, writes thus in his work on *Tumours* (fourth edition, page 432):

"Post-rectal dermoids sometimes open spontaneously in the perineum; the fistula is usually situated in the middle line of the perineum near the tip of the coccyx."

Again, on page 436, he says:

"Faulty coalescence of the cutaneous covering of the back often occurs over the sacral vertebrae, and gives rise to small congenital sinuses known as post anal dimples and coccygeal sinuses."

The congenital coccygeal fistula should not be confounded with the condition known as sinus over the sacrum and coccyx, which, though rare, is infinitely more commonly met with. Apparently Mr. Lockhart-Mummery fails to discriminate between these two totally distinct conditions, because he says that several years ago the late Mr. Goodall (evidently a misprint for Goodsall) described a number of cases of fistulae over the coccyx, which were difficult to heal, but did not recognize their nature.

Goodsall and I, in our book *Diseases of the Anus and Rectum* (Part I, p. 187), devote a chapter to a lesion which we term "sinus over the sacrum and coccyx," and give notes of ten typical cases. In this disease there is always a clear history of antecedent traumatism, leading ultimately to an abscess, which usually is allowed to burst spontaneously. The resulting aperture is nearly always situated to the left of the middle line, at or about the level of the upper extremity of the internal cleft and a long way from the tip of the coccyx. The site of the external opening is well shown in Fig. 69 of our book. That these sinuses are not congenital in origin appears from the following reasons:

1. Their appearance is never preceded either by a tumour or by a dimple.
2. The opening is never in the middle line.
3. The primary opening is never near the tip of the coccyx.
4. The sinus is never lined by skin.
5. The opening is usually surrounded by exuberant granulation tissue, similar to that met with in sinuses connected with carious bone.
6. The aperture often temporarily becomes closed—an impossibility if it were of congenital origin, owing to the epithelial lining.
7. Neither hair nor teeth are ever found in them.
8. The sinus can be effectually cured by simply laying it open freely, together with its lateral offshoots, and it is never necessary to excise any tissue whatever.

The mere fact that a sinus in the anal region is found to be lined by epithelium does not necessarily mean that it is of congenital origin. It is not an uncommon experience to find that the track of an anal fistula, if it has been in existence for a considerable time, and especially if it is short and wide in calibre, has become lined by epithelium from the external to the internal openings. This is not to be wondered at, because we know that many sinuses in connexion with long-standing bone disease become so lined, as does also the canal made through the lobule of the ear for the reception of an earring.—I am, etc.

London, W., June 7th.

W. ERNEST MILES.

INTERMISSIONS IN TRYPANOSOMIASIS.

SIR,—I see from the report of the meeting of the Royal Society of Tropical Medicine and Hygiene, on May 20th, in the *BRITISH MEDICAL JOURNAL* for May 28th, that both Dr. Manson-Bahr and Dr. Low were of opinion that cases of trypanosomiasis could not be regarded as cured until a period of at least three years had elapsed since the last appearance of the parasite in the blood.

In support of this view I may mention that, when in medical charge of the sleeping sickness area of Nyasaland in 1913, one of my patients, a child of 7, showed numerous trypanosomes (*T. rhodesiense*) in the blood on first examination, but none on many subsequent occasions until about a year later, when the trypanosomes reappeared, the symptoms, which had been in abeyance, returned, and death followed shortly afterwards. Owing to the opposition of the parents the child received no treatment of any kind, but was kept in his own village and away from the fly-infested bush.

The occurrence, in untreated cases, of such long intervals during which no trypanosomes are found in the peripheral circulation and the symptoms are stationary or absent, makes one hesitate before accepting Dr. Marshall's cases as permanent cures until a longer period has passed without relapse.—I am, etc.,

Duff House, Banff, May 31st.

PHILIP CONRAN.

ENUCLEATION OF THE TONSILS.

SIR,—In the *JOURNAL* of June 11th, under the heading of the Laryngological Summer Meeting, I am reported to hold the view that enucleation of the tonsils for enlargement is unjustifiable.

The published title of the paper which I was to read was not my own wording, and, as I was subsequently

informed, it gave rise to a general misunderstanding as to my views. My contention is that enucleation as the routine method for dealing with all tonsils which are enlarged is unjustifiable, especially as all enlarged tonsils are not diseased. I am of opinion that enucleation should be reserved for diseased tonsils or conditions which necessitate the removal of the tonsils, such as chronic peritonsillar abscess, etc. The scarring which frequently results from enucleation may seriously impair and even cause loss of a singing voice in an adult, and may prevent the formation of a singing voice when the operation is performed in childhood. The operation, moreover, is not unattended with danger from severe haemorrhage. There have been many deaths from this cause (I referred to a throat specialist who, up to a year or more ago, had lost four patients from haemorrhage), and not only is the frequency of its occurrence shown by the numerous instruments which have been devised recently to deal with this condition, but to the subject being considered of sufficient importance to call for a discussion at the forthcoming meeting of the British Medical Association at Newcastle.

London, W., June 13th.

T. MARK HOVELL.

THE NOTIFICATION FEE AND THE END OF THE WAR.

SIR,—When I see a case of infectious disease I promptly notify it by telephone (cost 6d.), in order to ensure speedy removal. Postal facilities in this village are somewhat mediocre. Then, *pro forma*, I send on the usual certificate (cost 1d.). Subsequently I receive 1s. for my trouble; net profit 5d. I am informed that I am doing this because we are still at war with Turkey. How much longer are we to remain at war with Turkey? And what has Turkey to do with it, anyhow?—I am, etc.,

H. W. POOLER, M.B.,

Honorary Secretary, Chesterfield Division.

Alfreton, June 13th.

Obituary.

JOHN MATTHEW FORTESCUE-BRICKDALE,

M.A., M.D. Oxon., M.R.C.P. Lond.,

Physician, Bristol Royal Infirmary.

THE death of Dr. Fortescue-Brickdale at the early age of 51 has deprived the profession in Bristol of a physician who combined a scientific knowledge of medicine with a wide knowledge of literature and a love of the arts, especially music. He was the younger son of the late Matthew Inglett Fortescue-Brickdale, conveyancing counsel to the Court of Chancery. Educated at Dulwich College, Christ Church, Oxford, and Guy's Hospital, he settled in Bristol in 1903. Soon after his arrival he was appointed assistant physician to the Royal Hospital for Women and Children. He also held the appointment of lecturer in pharmacology in the University of Oxford. In 1908 he was elected assistant physician to the Bristol Royal Infirmary and physician in 1919. At the time of his death he was physician to Clifton College and director of the University Public Health Laboratory.

During the war Dr. Fortescue-Brickdale served for two years in France, and contracted there a severe illness, from which he seemed never to have recovered completely. Upon his return from France he was given charge of a special centre at the 2nd Southern General Hospital, Southmead, for cases of chest wounds, on which he published a report in the *Quarterly Journal of Medicine* in 1918. His other publications included a book written in collaboration with Professor Francis, *The Chemical Basis of Pharmacology*, *A Practical Guide to the Newer Remedies*, *A Textbook for Nurses* (with Mr. Hey Groves), and *A Textbook of Pharmacology and Medical Treatment for Nurses*. His literary accomplishments made him a valued member of the editorial staff of the *Bristol Medico-Chirurgical Journal*.

Apart from his exceptional intellectual endowments, Fortescue-Brickdale was possessed of a singular personal charm. Grave of aspect, he had nevertheless a deep fund of humour, and could talk entertainingly on any topic. An old Oxford friend writes of him, "He was never one to reply monosyllabically to any remark; he had something of the touchstone in his composition; full of wit himself, he was as often the cause of wit in others." He took part

in many local activities, and for some years before his death had been churchwarden at All Saints Church, Clifton; for he belonged in religious thought to the school of George Herbert and Nicholas Ferrar. By family connexions he had long associations with Bristol, and his death is deeply deplored, not only by his medical confidants, and by the masters and boys of Clifton College, but by a wide circle of friends who knew his sterling worth. He leaves a widow and two sons.

We regret to record the death of Dr. Hyon Davies Jones, which took place at Mountain Ash on June 6th, 1921, at the age of 66. He was a native of Menai Bridge, Anglesey, and was educated at Edinburgh and Glasgow, and took the Diplomas of L.R.C.P. and S.Edin. in 1880. After acting as assistant to the late Dr. Benjamin Williams of Mountain Ash he went to Llangollen, North Wales, where he practised for about seventeen years. He returned to Mountain Ash in 1903 on the death of his brother, the late Dr. Daniel Davies-Jones, and became surgeon to Messrs. Nixon's Collieries and the Powell Duffryn Colliery. He was a very active member of the British Medical Association. He had been Chairman of the North Glamorgan and Brecknock Division, was a member of the Executive Committee, and represented the Division on the Branch Council; he had recently been appointed to represent the South Wales Branch on the Welsh National Memorial Association. He was very faithful in his attendance at the Division meetings and its committees, and only four days before his death was present at a Division meeting held at the General Hospital, Merthyr. He devoted a good deal of time to ambulance work; he was a lecturer and examiner in the St. John Ambulance Association, and had held very successful classes; recently he received a handsome presentation from one of his classes. Apart from his profession he took an active interest in the welfare of his town, and he and his family gave material and financial assistance to all good causes; during the war, though 60 years of age, he joined the V.F.C. and was a very active member; afterwards he received a commission. He was a kind and genial gentleman, very sympathetic to his patients, and greatly liked by them. He was skilled in his profession, but of a retiring disposition, and did not carry either his heart or his knowledge on the surface. He leaves a widow, two sons, and four daughters to mourn his loss. His two sons are members of the medical profession, the elder having been with his father, while the younger, recently qualified, is a resident at the King Edward VII Hospital, Cardiff. The local profession has lost a staunch friend who will be greatly missed in many spheres.

Dr. JOHN GOODWIN SHEA, who died suddenly on March 21st, was born in Dublin in 1856. He took the diploma of L.R.C.S.I. in 1880, and that of L.R.C.P.I. in 1882, and settled in Chesterfield in 1885; after acting for some years as assistant to the late Dr. Jefferies, he succeeded him in practice. Dr. Shea became F.R.C.S.I. in 1894, and graduated M.D. Durham in 1902. He was a J.P. of the borough of Chesterfield for many years, and on the honorary staff of the Chesterfield Royal Hospital. In June of last year he retired from active practice to Ewell, in Surrey. He was a past president of the Midland Branch of the British Medical Association.

The Services.

OFFICERS' ALTERNATIVE PENSIONS.

THE Ministry of Pensions announce that officers and nurses disabled by service in the great war who intend to claim alternative retired pay or pension based on pre-war earnings and present earning capacity, must make application on or before July 2nd, 1921, or before a year has elapsed since the last day of disability retired pay or pension, whichever is the later date. Applications for alternative pensions by widows of officers whose deaths were due to service in the great war must also be made before July 2nd, 1921, or within a year of the date of first award of the flat rate pension. A widow who may not be eligible at present owing to the receipt of allowances for children, but who may become eligible when these allowances cease, must make application before July 2nd, 1921, in order to establish her future claim. The provision relating to the time

limit is contained in the Royal Warrant of July 2nd, 1920, and was necessary as a proof of the Royal Warrant is applicable to his private disabled nurse. His earnings did not exceed £9 a year. In the case of officers' widows there is no fixed limit.

As the substitution of alternative retired pay or pension for the ordinary flat rate pension represents in some cases a substantial addition to the amount of the pension, disabled officers and nurses, and officers' widows who have not yet made application, should ascertain without loss of time whether they are entitled to the benefits of the alternative system. Applications and inquiries should be addressed to the Officers' Branch, Ministry of Pensions, Cromwell House Annex, Millbank, S.W. 1.

HONOURS.

The following awards are announced for services rendered during the operations in Afghanistan:

C S J - Colonel Charles W. Profitt, CMG, DSO, AMS
C J J - Colonel Thomas Stolarz, IMS, Lieut Colonel (acting Colonel) Corrie Hudson, IMS.

O. L. *Chief Engineer*—Captain (acting Lieut. Colonel) Alexander L. Blagum, B. A. M. C., temporary Captain Nitya David Joshi, I. M. S., Major or Thomas C. C. Leslie, B. A. M. C., Major (acting Lieut. Colonel) Herbert P. S. R. I. M. S., Major (acting Lieut. Colonel) Francis H. Shuttle, I. M. S., Captain and 1 Brevet Major (temporary Major) John A. Shotton, I. M. S., Captain and George W. Wallace, B. A. M. C., Major (temporary Major) 1 B. A. M. C., 1 Norman M. Wilson, I. M. S.
 7. *T. L. District Lieutenant and Capt.*—Major T. S. Diddling, O. B. E., B. A. M. C.

M C — Temporary Captain (Bansuri) I All Gupta, I M S. Temporary
 Lieutenant Major (Jore) Gopal Kanti, I M S. Temporary Captain (Bishan
 Ganesh) Mohila, I M S. Captain (acting Major) D. Reynolds, R A M C.
 Temporary Captain (Seyyannathar) Thambiah, I M S.

The following are also mentioned for distinction in service: Major (acting) Lieut. Col. J. D. Anderson, I.M.S., Major Duncan Coates, I.M.S., Captain Radhakrishna Dewani, I.M.S., F.C., Major (acting) Lieut. Col. J. E. F. Felling, M.S. Captain (acting) Major Richard L. Flowerdew, I.M.S., Captain Colt C. Harrison, R.A.M.C. (S.R.), Captain (acting) Lieut. Colonel John Patrick Huban, I.M.S., Captain Lauchlin John Hoell, I.M.S., T.C., Captain (temporary) Major Henry H. Mulholland, R.A.M.C., Captain (acting) Lieut. Colonel Denis F. Murphy, I.M.S., Lieutenant Atamahomed Tajmahomed Shaikh, I.M.B., T.C., Captain (acting) Lieut. Colonel Charles H. Smith, O.B.I., I.M.S., Captain Ralph R. Thompson, M.C., R.A.M.C., Captain (acting) Major Jagannath Bhadrishna Vaidya, I.M.S., Mrs. Alice Pennel, M.D., B.S., of the Madhav Mission Hospital, Patna, for their with twenty three members of the Indian Medical Department.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Litchfield Lecturer in Medicine.—Ernest Mallam, D.M., Magdalen College, has been appointed Litchfield Lecturer in Medicine for two years as from October 5th, 1921.

Lecturer in Animal Physiology.—Leonard Hill, M.B., F.R.S., has been reappointed Examiner in Animal Physiology in the Final Honour School of Natural Science.

Election of Members of the Board of the Faculty of Medicine.—The following have been re-elected members of the Board of the Faculty of Medicine: E. W. Anley Walker, D.Sc., D.M., Fellow of University College, J. H. Thursfield, D.M., Trinity College and St. Bartholomew's Hospital, Claude G. Douglas, B.Sc., D.M., Fellow of St. John's College.

The following have been approved at the examination indicated:

D.P.H.—*Part I*: H. L. Gault, J. B. Daab, A. Hunter, J. B. Overton, A. J. Partridge, Todd M. P. Wilson. *Part II*, and received the Diploma: H. L. Coulthard, T. J. Lloyd, G. W. Ronaldson, C. W. Sharpley.

William Brown, D.M., D.Sc. (Christchurch), Reader in Psychology in the University of London (King's College), has been elected Wilde Reader in Mental Philosophy.

UNIVERSITY OF CAMBRIDGE.

Dr. HAMILTON HARTPIDGE, Fellow of King's College, has been reappointed Senior Demonstrator in Physiology.

At a congregation held on June 10th the following medical degrees were conferred:

M D - A C Roxburgh
M.B. B Ch - J C Andrews, R A. W. Procter, M. B R. Swann,
J. W. McK Nicholl, T. B. Hobbs.
B Ch - A. J. Copeland

The Registrar calls the attention of the tutors and præceptors of colleges and of the deans of medical schools to the report of the Special Board for Medicine of May 4th, 1921 (*Report*, page 933, recommending important alterations in the times for the sending in of the names of candidates, and for the presenting of certificates for the Third Examination for Medical and Surgical Degrees. All medical students should be instructed to substitute the words *third year* for *tenth* or *thirty one* for *ten*, and *thirty-one days* for *three weeks*, on pages 11, 17, 35, 36 of the Regulations and Schedules for Medical and Surgical Degrees. The additional fee for late entry is £2.

UNIVERSITY OF LONDON.

DR. E. G. GRAHAM LITTLE has been elected by the Graduates of Medicine and Surgery of the University of London to serve his fifth term of office as their representative on the Senate.

The following have been recognized as teachers of the University in the subjects and at the institutions indicated:

London (Royal Free Hospital) School of Medicine for Women: Mrs. Anne L. Gilliat (Anaesthetics).
St. Mary's Hospital Medical School: Mr. C. W. G. Bryan (Surgery).
Mr. A. Fleming (Bacteriology).

Dr. Jobson Horne has been appointed Semon Lecturer. The lecture, entitled "The relationship of the larynx to pulmonary tuberculosis," will be delivered at the rooms of the Royal Society of Medicine on July 5th at 5 p.m.

The duration of the appointments of Professor A. D. Waller, F.R.S., and Dr. T. D. Lister, C.B.E., as director and treasurer respectively of the Physiological Laboratory has been extended to the end of 1921. Dr. John Fawcett has been appointed a governor of the Lister Institute of Preventive Medicine, and Dr. A. Thomas a governor of University College, Aberystwith.

The following have been appointed staff examiners in the subjects of examination for medical degrees 1921-22:

Anatomy: Professor G. Elliot Smith, F.R.S., and Dr. W. L. H. Duckworth. *Bacteriology:* Professor R. T. Hewlett. *Chemistry:* Dr. H. R. Le Sueur and Professor W. H. Lewis. *Forensic Medicine and Hygiene:* Drs. R. A. Lyster and W. G. Savage. *General Biology:* A. Eastwood, B.Sc., and Miss P. C. Esdaile. *Medicine:* Drs. J. Calvert, C.B.E., J. Fawcett, R. T. Todd, and Dr. J. S. Fairguy. *Mental Diseases and Psychology:* Drs. Todd, Fairguy, and Dr. J. S. Fairguy. *Obstetrics:* Dr. J. S. Fairguy, Sir W. Milligan, C.B.E., F.R.S., and Professor H. R. Dean. *Physiology:* Professor J. S. Macdonald, F.R.S., and Professor M. S. Pembrey. *State Medicine:* Drs. W. G. Savage and A. G. R. Foulerton, D.B.E. *Surgery:* J. Sherren, C.B.E., C. H. Farge, E. W. Hey Groves, and Professor G. E. Gask, C.M.G., D.S.O. *Tropical Medicine:* Dr. G. C. Low.

Mr. H. J. Waring, C.B.E., has been elected chairman of the Brown Animal Sanatory Institution Committee for the remainder of the year 1920-21. The annual report of the superintendent of the institution stated that during the year 6,040 animals, including 2,823 dogs, 2,660 cats, and 221 horses were treated there. The five lectures required to be given under the will of the late Mr. Brown were delivered by the superintendent during December at the Royal College of Surgeons, the subject chosen being influenza. The superintendent had continued in the laboratories his work on influenza for the Medical Research Council, and some interesting results are to be published shortly. He had also carried on researches on leprosy, and on the ultra-microscopic virus group in addition to examining a number of pathological specimens from the hospital. Mr. Twort's appointment as superintendent of the institution has been continued for one year as from June 1st, 1921.

Applications for the post of professor of medicine and director of the medical clinic at St. Mary's Hospital School, salary £2,000 a year, must be received by the Academic Registrar, University of London, not later than the first post on June 23rd.

The following candidates have been approved at the examination indicated:

DIPLOMA IN PSYCHOLOGICAL MEDICINE (with special knowledge of Psychiatry):—C. Farran-Ridge, W. Moodie, A. A. W. Potrie.

UNIVERSITY OF MANCHESTER.

THE following appointments have been made: *Demonstrators in Pathology:* P. I. C. Gibson, M.B., B.S., and A. Haworth, M.Sc., M.B., Ch.B. *Demonstrators in Anatomy:* Georgina May Duthie, M.B., Ch.B., and R. C. Shaw, M.R.C.S.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

New Fellows.

At a meeting of the Council of the Royal College of Surgeons, held on June 9th, with Sir Anthony Bowlby, K.C.B., President, in the chair, diplomas of Fellow were conferred upon the following twenty-five candidates (including one woman) who have passed the requisite examinations and have complied with the by-laws—namely:

K. B. Bellwood, E. C. Eowden, G. N. Brandon, G. W. Carte, H. Corsi, R. Coyle, S. G. Dunn, J. A. W. Ebdon, Sataprija Ghosh, J. B. Haycraft, S. N. Hayes, O. S. Hillman, J. B. Hunter, C. M. Jones, O. R. M. Kelly, T. P. Kilner, C. Lamiraud, H. M. Livingston, R. P. S. Mason, R. L. Newell, H. C. W. Nuttall, K. G. Pandalai, R. H. O. B. Robinson, F. W. Watkin-Thomas, H. W. Wookey.

Mr. James Sherren and Mr. L. Bathe Rawling were elected members of the Board of Examiners in the vacancies occasioned by the retirement of two previous members of the Board.

The following were elected as examiners in anatomy and physiology for the Fellowship for the ensuing year:

Anatomy: A. R. Thompson, J. E. S. Frazer, G. Gordon-Taylor, W. F. Haslam. *Physiology:* H. Willoughby Lytle, F. A. Bainbridge, A. Rendle Short, J. Mellanby.

The following recommendations for examiners in other subjects were adopted by the Council:

Elementary Biology: T. W. Shore, J. P. Hill. *Anatomy:* F. G. Parsons, David Hepburn, Arthur Thomson. *Physiology:* G. A. Duckworth, H. E. Roaf. *Midwifery:* G. F. Darwall Smith.

Cuthbert Lockyer, G. Drummond-Robinson, C. Hubert Roberts, Diploma in Public Health; Sir F. W. Andrews, F. N. K. Menzies, Diploma in Tropical Medicine and Hygiene; H. B. G. Newham (Bacteriology); G. C. Low (Diseases and Hygiene of Tropics). Diploma in Ophthalmic Medicine and Surgery; J. H. Parsons, H. W. Lytle, Mott.

The following professors and lecturers were appointed for the ensuing collegiate year:

Historian Professors.—Sir Arthur Keith: Six lectures on "The comparative osteology of human races," illustrated by collections in the Museum. Harold Burrows, C.B.E.: Two lectures on "The results and treatment of gunshot wounds of the blood vessels." Alfred G. T. Fisher: One lecture on "The pathology of chronic arthritis, with remarks on the basal principles of treatment of joint disease as indicated by anatomical and physiological observations." Charles A. Pannett: One lecture on "Hydronephrosis." Alan H. Todd: One lecture on "Orthopaedic aspects of rheumatoid arthritis." Kenneth M. Walker: One lecture on "Enlargement of the prostate."

Arts and Gale Lecturers.—V. Zachary Cope: One lecture on "The nerve supply of the parietal peritoneum and superperitoneal tissues." F. W. Edridge-Green, C.B.E.: One lecture on "New researches in colour vision." Swale Vincent: One lecture on "A critical examination of current views on internal secretion."

Erasmus Wilson Lecturer.—S. G. Shattock: Six demonstrations or lectures in the Museum.

—Sir Arthur Keith: Six demonstrations or lectures in the Museum.

—Sir Charles A. Ballance: Historical lecture.

A vote of congratulation was accorded to Sir Arthur Keith on the honour of knighthood conferred on him.

It was resolved that the examinations for the primary Fellowship should be held in June and December in 1922 and until further notice.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.

At the monthly meeting of the Royal Faculty of Physicians and Surgeons of Glasgow held on June 6th, the following were admitted (after examination) as Fellows: J. H. Fyfe, A. M. Laurie, T. T. Read, J. D. Wright.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the President and Fellows held on June 3rd the Most Rev. and Right Hon. John H. Bernard, D.D., Provost of Trinity College, Dublin, was unanimously elected an Honorary Fellow of the College.

The following candidates, having passed the Membership Examination, were duly admitted Members of the College: L. Abrahamson, J. W. Bigger, C. Dickson, J. D. Sandes.

Medical News.

DR. MILES HARRIS PHILLIPS, surgeon to the Jessop Hospital for Women, Sheffield, has been appointed Professor of Obstetrics and Gynaecology in the University of Sheffield.

DR. E. F. HOARE, of the Middle Temple, and Dr. E. G. ANNIS, of Lincoln's Inn, have been called to the Bar.

A VACATION course of post-graduate instruction has been arranged at the Post-Graduate College, West London Hospital, Hammersmith, W., commencing on August 2nd and ending on August 27th. Further particulars can be obtained on application to the Secretary of the College.

DR. W. M. PALMER, of Linton, author of a number of works on the antiquities of Cambridgeshire, has been elected a Fellow of the Society of Antiquaries of London.

THE Council of the Royal Society of Medicine has awarded a Gibson Research Scholarship to Miss Gertrude M. A. Herzfeld, M.B., Ch.B., F.R.C.S. Edin., of Edinburgh. The scholarship will be held for two years, with a for a third year.

WE are asked to state that Dr. Rollier has arranged to give a short post-graduate course of demonstrations on heliotherapy, at Leysin, from August 16th to August 20th.

THE new offices of the General Nursing Council for England and Wales at 12, York Gate, at the corner of Marylebone Road, were opened by Princess Christian on June 10th. The Council was called into existence by the Nurses' Registration Act, 1919, primarily to form and keep a register of nurses for the sick, in accordance with the provisions of the Act. It consists of two persons appointed by the Privy Council, two by the Board of Education, and five by the Ministry of Health, together with sixteen nurses nominated by the Central Committee of Nurses, the College of Nursing, for the Nurses Association. Of the five members nominated by the Ministry of Health, two—Sir T. Jenner Verrall, LL.D., and Dr. E. W. Goodall, O.B.E.—were appointed at the suggestion of the British Medical Association.

The fiftieth inter-hospital athletic sports will be held at Queen's Club, Borens Court, S.W., on Tuesday, June 28th, commencing at 2.30 p.m. The prizes will be presented by Viscountess Goshen. Further particulars can be obtained from Mr. L. G. Housden, Honorary Secretary U.H.A.C., Guy's Hospital, S.E.

DR. JAMES GRANT, who has practised at Rhynie, Aberdeenshire, for thirty-three years, has been presented by his patients and friends with an illuminated address and a cheque for £500, in appreciation of his valuable services to the community.

The Ministry of Health has, at the request of the Metropolitan Water Board, issued a circular to metropolitan borough councils and sanitary authorities within the area of the Board inviting them to restrict the use of water for the watering of streets and the flushing of sewers. The shortage of the metropolitan supply of water is attributed to the prolonged drought.

A COURSE of twelve practical demonstrations on the management and feeding of infants and young children is being given on Tuesdays and Thursdays at the St. Marylebone General Dispensary, 77, Welbeck Street, W., by Dr. Eric Pritchard. Arrangements have been made to visit the Nursing Training School, 1, Wellgarth Road, Golders Green, N.W., to see the methods employed there in dealing with infants. The fee for the course, which commenced on June 14th, is £2 2s.

The annual post-graduate class in oto-rhino-laryngology will be held in Professor Moure's clinic at Bordeaux from July 18th to July 30th.

The Department of Medical Zoology in the School of Hygiene and Public Health, Johns Hopkins University, has arranged to send an expedition to Porto Rico this summer to study malaria and other problems arising out of disease-producing protozoa.

The second International Congress for the Protection of Childhood will take place at Brussels from July 18th to 21st. The subscription for members is 25 francs, for associate members 10 francs. The organizing secretary is M. H. Velge, 27, rue de Turin, Brussels.

At the last meeting of the Central Midwives Board for England and Wales, Sir Francis Champneys in the chair, it was reported that copies of the Central Midwives Board (Terms of Office) Order, 1921, had been forwarded from the Ministry of Health, the Order giving effect to the representation made by the Board on January 20th, 1921, that each of the members who, according to the Central Midwives Board (Constitution) Order, 1920, were to be appointed for a term of three years, should be appointed instead annually. It was announced that the Home Office had informed the Midwives Institute that, by virtue of the Regulations to be issued under the Dangerous Drugs Act, 1920, certified midwives who had notified their intention to practise would be authorized, under appropriate conditions, to purchase and be in possession of medicinal opium for use in the practice of midwifery.

The German Congress of Internal Medicine will be held at Wiesbaden in 1922 under the presidency of Professor Wenckebach. The subsequent congress will be held in Vienna.

An international congress of ophthalmology will be held at Washington from April 18th to 22nd, 1922, under the auspices of the American Ophthalmological Society, the Ophthalmological Section of the American Medical Association, and the Academy of Ophthalmology and Oto-rhino-laryngology.

THE twenty-sixth Dutch Congress of Public Health will be held in September at Arnheim, when the following subjects will be discussed: (1) Notification of infectious diseases; reporters, Kuiper (Amsterdam) and Kapsenberg (Groningen). (2) Destruction of vermin; reporters, Ringeling and Wolff (Amsterdam).

THE first stone of a Rockefeller tuberculosis dispensary has been laid at Bordeaux to commemorate the 284 American nurses who died during the war.

THE Municipal Council of Paris has decided to increase the fee payable to medical men summoned by the police to 20 francs.

AT a recent meeting of German scientists measures were agreed on as to the preservation of the most important features of scientific research under present social conditions. It was decided that subsidies should be secured for the 400 most important of the (roughly) 3,000 scientific journals published in German. To meet the lack of foreign publications a single large levy was voted to provide German readers with the most important foreign journals. Expedients were also found to combat the

shortage of research apparatus, drugs, experimental animals, and the like by centralizing the machinery for their purchase and distribution.

THE late Mr. Rutherford J. Pye-Smith, F.R.C.S., Emeritus Professor of Surgery in the University of Sheffield, has left estate of the gross value of £3,535, of which £3,603 is net personality. He left the residue of his estate to his wife for life, and subject to her interest bequeathed £1,000 to the University of Sheffield for the chair in surgery, £100 to the Sheffield Royal Hospital, and £20 each to the Broompark Mission, Sheffield, the Edinburgh Medical Mission, and the Pye-Smith Scholarship Fund, Walthamstow Hall, Sevenoaks.

AT a meeting of the Society of Public Analysts on June 1st a paper on the composition of so-called egg powders was read by Beach, Needs, and Russell, comparing them with ordinary baking powders. A table of compositions was given, and it was suggested that a standard might be laid down for a minimum percentage of actual egg in such preparations.

DR. FRANCIS J. STEVENS has retired from the post of Medical Officer of Health to the Borough of Camberwell, after thirty years' service.

THE International Labour Bureau at Geneva has published figures showing that eleven nations (not including Russia, Turkey, Bulgaria, and Australia) have had 5,500,000 men disabled in the war. Of this number France has 1,500,000; Germany, 1,400,000; Great Britain, 1,170,000; Italy, 570,000; the United States, 290,000; Czechoslovakia, 175,000; Canada, 82,000; Rumania, 81,000; and Belgium, 40,000. Reports sent by the different Governments show that only a few of the disabled men now remain in military hospitals, and that the majority of the severely wounded who have been properly trained and provided with suitable appliances are capable of earning their livelihood, but there is difficulty in finding occupation for them all.

THE American Hospital Association will hold its annual conference at West Baden, Indiana, from September 12th to 17th.

A HOSPITAL ship to contain 500 patients is being built at Philadelphia.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

Notice to be taken of their communications with their names—of course not.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 422, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 422, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, <i>Aitology</i> , Westrand, Lo	
2. FINANCIAL MANAGER (Advertisement), 260, Gerrard.	MANAGER telephone.
3. MEDICAL SECRETARY, <i>Mediscera</i> , Westrand, London; telephone, 2530, Gerrard. The address of the Irish Office of the 16, South Frederick Street, Dublin telephone, 4737, Dublin), and of 1 Square, Edinburgh (telegrams: Associate Edinburgh; telephone, 4361, Central).	

QUERIES AND ANSWERS.

DR. J. McOSCAR, of Buxton, asks whether mixed staphylococcus vaccine has been used in infantile eczema, which, when occurring at the time of dentition, may last for months.

"T. M."—A newly appointed medical officer of health to an urban district should obtain from the clerk to the council the Sanitary Officers (outside London) Order, dated December 13th, 1910, Article xix of which defines the duties of a medical officer of health. Textbooks he will find useful are *Hygiene and Public Health*, by Whitelegge and Newman, published by Cassell and Co.; *Hygiene*, by Notter and Firth, published by Longmans and Co.; and *Sanitary Law and Practice*, by Robertson and Porter, published by the Sanitary Publishing Company, Ltd.

"ONYRIS VERMICULARIS."

Dr. K. R. COLLIS HALLOWES (Peebles) writes in reply to "Worried": (a) Take care to prevent reinfection by prohibiting articles of diet that may be infected. (b) Internal administration of sulphur in increasing doses. (c) Wash round anus at bedtime, thoroughly dry, and apply a weak mercurial ointment.

"H. D. J." writes: If "Worried" tries aloes wine, about half an ounce, taken early in the morning on an empty stomach once or twice a week, he will find that *Oxyuris vermicularis* is destroyed; also the purgative mineral waters, as "Rubinat" or "Apenta," taken three times a week, will be beneficial. For many years I suffered from the same complaint and cured myself with the above treatment. Reinfection plays an important part and great personal cleanliness is necessary, specially washing the hands and fingers after going to the w.c. The use of lettuce, as in salads, and watercress should be avoided; my experience is that they are a fruitful source of entozoa.

INCOME TAX.

"A. M." and a friend have bought a practice for £2,000, which is to be discharged by the handing over of the first two years' receipts from panel practice.

"A. M." and his colleague are in partnership and are therefore assessable in one sum—less, of course, the personal allowances applicable to each. The panel receipts will have to be regarded as (gross) income of the firm; the fact that they are paid away in discharge of the capital liability to the outgoing practitioner does not affect their taxability.

"M. G." inquires whether he can claim the average of three years in connexion with the assessment of his fixed salary as full-time public health officer. In the first two of the three years he was in the army.

"* Legally the salary is assessable on the basis of the current year and cannot be averaged with previous earnings. We believe that concessions were made in some cases where the three years' average did apply—for example, that a locum-tenent might average his military earnings, though they were dissimilar in nature; but we have not heard of any concession that would cover our correspondent's case.

"A. K." asks for further information with regard to the allowances for interest paid to a bank.

"* The primary claim is that repayment is due on that portion of the taxed income which goes in payment of the overdraft interest; there is sometimes a secondary claim—namely, that the income as reduced by the payment is sufficiently low to permit of some allowances being claimed from which the claimant would otherwise have been barred. For instance, if the total income for 1919-20 were £1,050, of which £100 was paid away as bank interest, then the claimant would be entitled (a) to repayment on £100 and (b) to an adjustment in view of the fact that his net income was below £1,000, and he was therefore entitled to pay on that amount at a lower rate than before. We understand from the correspondence that for 1919-20 "A. K." had repayment under both heads, but that for 1920-21 the secondary claim does not arise, seeing that the rate of tax payable on his net income is not affected by the reduction caused by payment of the bank interest.

LETTERS, NOTES, ETC.

NEED FOR POST-GRADUATE INSTRUCTION IN MOUTH
SEPSIS.

Dr. M. ASTON KEY (Southsea) writes: I confess to a considerable degree of sympathy with your dental correspondent, "A. B. C." (June 4th, p. 842), in his endeavour to secure adequate opportunities for dealing with the treatment of oral sepsis in a post-graduate course.

In the practice of general medicine every week brings us some fresh evidence of the varied results, early or late, arising from this trouble. We who are in the first attacking line know the value of close co-operation with the dental surgeon, not merely to the extent of sending our patients to him, but in discussing with him both the clinical symptoms which we attribute to the sepsis, and also the mode by which he intends to attack it from his standpoint.

The interpretation of skiagrams, the use of high-pressure sprays, of vaccines, and of the many other lesser methods of treatment are all subjects which well repay conferences between physician and dental surgeon; as much and more may be said of wholesale extractions and the period of time over which they are distributed. It is right that we should know the treatments other than extraction which are at the disposal of our dental brethren; if for no other reason, it is useful in dealing with cases in which extraction is difficult or undesirable. As Dr. Pye-Smith used to say, "Commonest things occur most often," and we see the evil results of oral sepsis many times daily. One cannot but feel that such a subject deserves thorough handling in any post-graduate course.

"M.R.C.S." writes to express the opinion that after the paper by Sir W. H. Wilcoxon on infective arthritis (June 4th, p. 801), in which the writer laid stress on the fact that the commonest cause of infection was to be found in connexion with the teeth sockets, and Dr. William Hunter's paper on "The coming of age of oral sepsis" (June 11th, p. 859), there ought to be little need for "A. B. C." to ask whether any post-graduate course can be considered to be complete without some practical instruction in this disease, with its far-reaching effects. "M.R.C.S." is very glad to see there is a prospect of the deau of the medical school to which "A. B. C." is attached arranging for a demonstration.

TOXINS AND NERVE CENTRES.

Mr. H. V. DREW, F.R.C.S. (London, W.), writes: In 1913 I was privileged to observe the experimental work then being conducted by Dr. Teale at University College Hospital laboratories, by which he demonstrated that antitetanus toxin would prevent tetanus in animals if given before tetanus inoculation, but had no effect afterwards, and saw this illustrated during the war, when the subjects of tetanus were being, so to speak, "flooded" with tetanus antitoxin, those cases only recovering, as was observed by Hippocrates, which were not acute or chronic. Dr. Teale also demonstrated the reason—namely, that the antitoxin only reached the spinal cord through the nerves themselves and not through the general circulation, the same as in tetanus poisoning. This he clearly showed by coloured injections, which were easily traceable. My object in referring to the above experiments is again to emphasize the necessity of recognizing the bed-rock principle that all diseases are controlled by the vital centres in the medulla, until these are put out of action by the toxin of the special disease of which the patient is suffering—by the direct influence it exerts on those centres by its toxin attacking through the intraspinal fluid, in which they are bathed, and through which only can they be reached. In 1916 I was greatly impressed by the marked resemblance in certain cases between acute pneumonia and cerebro-spinal meningitis and the immediate relief to both afforded by tapping the theca, and the possible differential diagnosis effected by the examination of the cerebro-spinal fluid. Ever since, on reflection, I am more and more convinced that as the vital centres in the medulla control all the vital processes in health, so they are the first affected in disease, and that it is only by attacking the poisonous toxin through the spinal fluid, and by prevention of direct injury to these vital centres, by tapping, pending the results of some form of antitoxin treatment, through the spinal fluid, that success can be attained.

Since you last published a letter from me on this subject, I am glad to see that on these lines sleeping sickness has been successfully attacked, and I only wonder how many thousands of lives have been unnecessarily sacrificed in other diseases since you first published my contribution on this subject in 1917—and several notes since.

"THE BUFF BOOK."

We have received communications from Dr. W. B. Norcott (Wallington, Surrey) and Dr. Charles Wheen (London, W.), stating that their names have been inserted in the "Buff Book" without their knowledge or consent.

A CATCH.

A CORRESPONDENT invites our opinion upon the following extract from a description of the test match in the *Times*:

"It was a powerful stroke, and Mr. Hendry, after stopping the ball high above his head, finally got control of it as he lay prone on his back."

The anatomist to whom we have referred the matter suggests that the last four words are a misprint for "supine on his face."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 32, 33, 35, 37, and 38 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34, 35, and 36.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under ...	0	9	0
Each additional line ...	0	1	6
Whole single column (three columns to page) ...	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post restante letters addressed either in initials or numbers.

702. Barium Sulphate in the Treatment of Gastric and Duodenal Ulcer.

GALAMBOS (*Wien. klin. Woch.*, February 10th, 1921) recommends the substitution of barium sulphate for bismuth subnitrate in the treatment of gastric and duodenal ulcer, as it possesses the following advantages, namely, complete insolubility, harmlessness, cheapness, and tastelessness. The action of barium sulphate generally resembles that of bismuth salts in its forming a protective layer over the gastric or duodenal ulcer, as is proved by x-ray examination. The constipating action of barium sulphate, on the other hand, is less marked than that of the bismuth salt, and it therefore leaves the gastro-intestinal canal more rapidly than bismuth. Another advantage of barium sulphate is that while bismuth to its conversion into the sulphide, gives a greenish-black colour to the stools, and thus interferes with the naked-eye recognition of occult haemorrhage, the white barium sulphate makes the presence of haemorrhage in the stools more distinct. Although Galambos has hitherto employed barium sulphate only for gastric and duodenal ulcer, he recommends it for other diseases in which bismuth is commonly used, such as dysentery, paratyphoid fever, cholera, enteritis, and proctitis due to various causes.

703. The Residual Nitrogen in Infectious Diseases.

WAGNER (*Wien. Arch. f. inn. Med.*, August, 1920), from a study of cases of typhus, relapsing fever, enteric fever, malaria, dysentery, pneumonia, tuberculosis, septicaemia, encephalitis lethargica, and various other febrile conditions, comes to the following conclusions: (1) Every acute febrile disease may give rise to azotaemia. In chronic febrile processes this condition is usually absent. (2) The rise in the residual nitrogen in the blood does not depend upon the height of the temperature, and is apparently independent of the condition of the kidneys, but probably depends on the degree of intoxication. Considerable differences are to be found in the intensity of the effect of the various pathogenic organisms or their toxins on the increase of urea in the blood. The deficiency of water in the body is not sufficient to explain the azotaemia in diseases associated with considerable loss of water. (3) In the majority of cases the excretion of urea through the kidneys rises parallel with the increase of urea in the blood, even when nephritis is present. (4) A large amount of urea in the blood (over 100 mg. urea to 100 c.cm. of blood) must not be regarded as a bad prognostic, especially when it is only transient. On the other hand, a persistent azotaemia which shows no tendency to diminish, or even increases, should always be regarded as an unfavourable sign.

704. Saccharin Intoxication.

GRUNDFEST (*Zentralbl. f. inn. Med.*, March 26th, 1921) remarks that, in spite of the almost universal employment of saccharin during the last few years, he has seen only one case of typical saccharin intoxication, although occasionally some of his patients have always complained of headache and loss of appetite after taking it. The typical case was that of a man, aged 45, who, three days after taking saccharin for the first time to sweeten his coffee, presented a bloated face, swollen eyelids, and chemosis, together with a feeling of irritation in the larynx. The temperature was normal, the faucial and laryngeal mucous membranes showed nothing special, and the voice was not hoarse. There was no albumin in the urine. Continuing the saccharin the symptoms rapidly disappeared. Some days later, when the patient had taken only three spoonfuls of coffee sweetened with saccharin, the feeling of irritation in the throat returned. The case was therefore an example of extreme idiosyncrasy for saccharin.

705. Pernicious Anaemia and Malaria.

CODA (*Il Policlinico, Sez. Med.*, March 1st, 1921) records two cases in malarial subjects, aged 42 and 56 respectively, who presented all the symptoms of pernicious anaemia. The blood picture in the first case showed haemoglobin 20 per cent., red cells 650,000, colour index 1.5, leucocytes 3,000, pronounced poikilocytosis, anisocytosis, megalocytes, polychromasia, and megaloblasts. There were also anorexia, diarrhoea, and achylia gastrica. In the second case, in which achylia gastrica was also present, the red cells numbered 1,200,000, the leucocytes 4,000, haemoglobin 35 per cent., colour index 1.4. There were also anisocytosis, anisochromia, a few normoblasts, megaloblasts, and myelocytes. Recovery took place in both cases under quinine treatment.

SURGERY.**706. Radical Cure of Haemorrhoids.**

DRUECK (*Amer. Journ. of Surg.*, April, 1921) insists upon as thorough preparation of the patient for an operation for haemorrhoids as for a laparotomy, and his technique is described for operating under local anaesthesia with 0.5 per cent. solution of apothesine or procaine. Minute details are given for infiltrating the whole field of operation and blocking the sphincter and coccygeal nerves. Slow but thorough dilatation of the sphincter is essential and requires careful manipulation to prevent tearing the mucous membrane at the anal margin, since trauma increases the risk of perirectal abscess formation. When the haemorrhoid has been brought well outside it is distended with a solution of 0.5 per cent. quinine and urea hydrochloride, which is injected also into the pedicle and into the normal mucous membrane for half an inch above the pile. This is then bluntly dissected out through two incisions in the mucous membrane commencing above the tumour and carried down on each side. The pedicle, after being thoroughly freed, is firmly tied, one end of the ligature being passed through the stump and tied across the encircling ligature to prevent slipping. The patient is kept on his side or face for the first day to lessen the tendency to swelling, and is restricted to liquid diet. Soup, broth, egg albumen, buttermilk, and cream, but not milk, are given two-hourly, followed by semi-solids on the second day. At the end of this time 6 oz. of liquid paraffin are injected through a soft catheter, and each day after an 8-oz. enema of physiological salt solution is given. Among advantages claimed for this method are: non-injury of the sphincter muscles, freedom from secondary haemorrhage, a smooth level resulting scar, and impossibility of recurrence.

707. Spontaneous Rupture of the Bladder.

HANSEN (*Hospitalstidende*, April 6th, 1921) notes that spontaneous rupture of the bladder precipitated by such acts as defaecation, micturition, lifting weights, and blowing a trumpet, is far less common than traumatic rupture. To the question Can retention of urine alone provoke rupture of a normal bladder? he can give no definite answer, for the cases bearing on this point have, for the most part, occurred under the influence of alcohol. And it is notorious that under alcohol rupture of the bladder may be traumatic without the patient being able to remember the trauma. In this connexion the author records the case of a man, aged 55, whose rupture of the bladder did, indeed, occur during a drinking bout, but as during this bout he was quietly locked up in his own flat, it is unlikely that he had received a blow over the bladder. Nor was there any evident sign of such a blow. The case terminated fatally, and the necropsy showed slight adenomatous enlargement of the prostate. There was no other cause found to account for the retention of urine and there was no marked evidence of cystitis. The bladder had given way in the sagittal plane; a 10 cm. long, clean-cut tear ran down from the top of the bladder through its posterior wall and communicated with the peritoneal cavity. Careful microscopic examination of the walls of the bladder near this tear revealed no abnormal fatty infiltration or hyaline degeneration of the muscles; there was only some infiltration with blood. This case would, therefore, suggest that a practically normal bladder may rupture spontaneously if over-distended.

708. Pneumoperitoneum and Radiological Diagnosis.

STEIN and STEWART (*Arch. med. Belg.*, February, 1921) have employed the method of pneumoperitoneum or insufflation of gas into the abdominal cavity in 150 cases without ill effects, as a preliminary to radiographing the abdominal organs, which are thus separated from one another and present distinct outlines. The method is, they hold, of great value in the diagnosis of various lesions, especially of large organs such as the liver, spleen, and kidneys, and it is the only process which reveals adhesions between the abdominal wall and the organs contained in the abdomen or shows the contents of a hernia. The choice of the gas to be employed depends upon circumstances. If the examination is of short duration, like screening the liver or gall-bladder, carbon dioxide should be used, because it is absorbed in about twenty minutes. A mixture of equal parts of carbon dioxide and oxygen is absorbed in thirty-five to forty minutes. Oxygen disappears slowly, and is suitable for prolonged examinations, such as complete examination of the abdominal cavity. The contraindications to pneumoperitoneum mentioned are acute

peritonitis and the presence of serious circulatory or respiratory disturbance. The technique is simple, the materials required being a lumbar-puncture needle, two rubber tubes each one metre in length, a rubber bag containing four litres like that used in gas anaesthesia, and a receptacle containing the gas. One of the rubber tubes connects the receptacle with the bag, and the other the bag with the needle. The patient, who has been purged and had his bladder emptied, is laid on the table to be screened, having received an injection of morphine a quarter of an hour before the operation. The skin of the abdomen is rendered aseptic with iodine, the needle is introduced two to three fingerbreadths below the umbilicus into the peritoneal cavity, and gas is then allowed to pass slowly in by turning a cock. The amount of gas used depends upon the state of tension of the abdominal wall, and varies from two to four litres. When sufficient gas has been introduced to make the wall as tight as a drum the needle is rapidly withdrawn and the puncture wound closed.

709. Intraperitoneal Infusion in Adults.

LOEWENHARDT (*Zentralbl. f. inn. Med.*, March 3rd, 1921) recommends for use in adults the method of saline infusion introduced by Weinberg in infants, the technique of which he describes as follows: The patient's pelvis is slightly raised, and the skin of the hypogastrium disinfected with iodine on the right or left side according to choice. The junction of the centre and middle thirds of the imaginary line connecting the umbilicus and anterior superior spine is chosen as the site of injection. The needle is introduced by a slight turning movement, so that every layer which is traversed is felt. When the peritoneum is pierced some fluid is run in under pressure so as to drive any part of the bowel out of harm's way. One and a half to two litres of fluid may then be injected in the usual way, the fluid being either normal saline or Ringer's fluid to which dextrose or drugs may be added. Intraperitoneal infusions are indicated generally in all cases where a larger quantity of fluid has to be injected. They are always to be preferred to subcutaneous injections, as apart from the slight prick of the needle they are entirely painless, and the time required for the infusion is three to four times less than that of subcutaneous injection, while the power of absorption of the peritoneum is considerably greater than that of the subcutaneous tissue. Loewenhardt prefers intraperitoneal infusion to intravenous injection in all cases in which there is any technical difficulty about the latter. He has never observed any sign of peritoneal irritation following his method.

710. The Action of Spinal Anaesthesia on the Hepatic and Renal Functions.

RANUCCI (*Il Policlinico, Sez. Prat.*, March 7th, 1921), owing to the disagreement among various writers as to the action of spinal anaesthesia on the kidneys and liver, made investigations on 67 cases which had undergone spinal anaesthesia for various operations with a mixture of stovaine 4 cg. and novocain 2 cg. The urine before operation was normal in all but 2 cases, in which there was slight albuminuria with granular casts. The examination was commenced with the first urine passed after the operation and continued for about a week. The ages of the patients ranged from 16 to 75. The post-operation course was normal in each case. With a few exceptions, in which a catheter was required for a few days, micturition was spontaneous in each case. Diminution of the total quantity of urine was constant. In the two cases in which albuminuria was present before the operation there was only a slight increase in the amount of albumin in the urine. In 20 cases in which variations in the nitrogen of the blood and urine were investigated before and after the operation, Ranucci found that after the operation the nitrogen was always slightly increased in the blood, and considerably in the urine. He never found glucose, acetone, bile pigment, urobilin, or acetic acid in the urine. In 21 cases, or 34 per cent., albuminuria was present, but never more than 1 in 1,000. In 6 cases albuminuria was present in the first specimen of urine passed after the operation—that is, six to twelve hours after the intraspinal injection. In 5 cases hyaline and granular casts were present. In no case did the duration of the albuminuria exceed seven days. Ranucci considers that the albuminuria is due, not to the action of the stovaine on the renal epithelium, but to its action on the nerve centres. His observations show how slight and transient are the lesions caused by spinal anaesthesia in the organism, especially in the liver and kidneys. The method can therefore be adopted in patients with renal and hepatic diseases with much less danger than is associated with general anaesthesia.

711. Trauma and Parenchymatous Keratitis.

ROSICA (*Il Policlinico, Sez. Prat.*, February 28th, 1921) has observed more than a hundred cases of parenchymatous keratitis in the ophthalmological clinic at Rome and in military hospitals at Rome, Florence, and elsewhere, 80 per cent. being undoubtedly due to inherited syphilis, with a positive Wassermann reaction. In only two cases could the keratitis be attributed to trauma, which in one case was an occasional cause in a subject of inherited syphilis, while in the other, who presented the clinical picture of Fuchs's disciform keratitis, there was a small area of loss of epithelium in the centre of the cornea. The course of both these cases was completely different from the typical form of diffuse parenchymatous keratitis. Rosica comes to the following conclusions: (1) In typical parenchymatous keratitis a trauma does not constitute the determining cause. Although it is possible in very rare cases that it may be an occasional cause, Rosica has never seen or read of a case, with the possible exception of one reported by Armaignac, in which keratitis which occurred in one eye after an injury was followed by similar lesions in the other eye after an interval of seven weeks. (2) In atypical forms of parenchymatous keratitis, on the other hand, trauma may constitute the determining cause, as in various forms of disciform keratitis and in cases of circumscribed and unilateral interstitial keratitis.

712. Torsion of the Gall Bladder.

HANSEN (*Hospitalstidende*, March 30th, 1921) finds that torsion of the gall bladder is so rare that barely half a score of cases have been recorded. The condition has never been diagnosed before operation, and has usually been confused with acute cholecystitis or appendicitis. Only in one case have gall stones been found in connexion with the torsion, and though the symptoms were most alarming and most of the patients were women of about 70, an operation has usually been followed by complete recovery. The author supplements this general survey with an account of a woman, aged 79, who suddenly developed violent abdominal pain with repeated vomiting of brownish-green, foetid fluid. She was admitted to hospital twenty-four hours later with the diagnosis of intestinal obstruction. Examination led to the opinion that she was suffering from impaction of a gall stone in the cystic duct. Laparotomy revealed an hour-glass gall bladder, the neck of which was twisted 360 degrees in the direction of the hands of the clock. The gall bladder was easily untwisted and its lower portion resected. Neither the gall bladder nor bile ducts contained stones. The patient was perfectly well on her discharge. Considering the thickness of the neck of the hour-glass, it is curious in the first place that the torsion should have occurred, and in the second place that it should not have corrected itself.

OBSTETRICS AND GYNAECOLOGY.

713. Pathology and Treatment of Leucorrhoea.

ACCORDING to REIDER (*Amer. Journ. of Obstet. and Gynec.*, April, 1921), leucorrhoea not dependent on any morbid state may precede or succeed a normal menstrual function in a healthy woman, irrespective of age; the leucorrhoea of children consists almost entirely of a discharge from the glands of the vulva and is commonly associated with constipation, ascariasis, or uncleanliness. Two chief varieties of pathological leucorrhoea may be recognized, the former being the more common and more obstinate: (1) mucous or cervical leucorrhoea, in which the discharge consists chiefly of mucous corpuscles and plasma, secreted chiefly in the follicular canal of the cervix; (2) leucorrhoea of the epithelial variety, where the discharge is secreted by the vaginal portion of the os and cervix and is freely mixed with scaly epithelium and its debris. The assumption of a mucopurulent character is due to bacterial contamination; gonorrhoeal infection is specially prone to persist in the os and cervical canal after the vaginal walls and the urethra have become healthy. The great majority of cases require both constitutional and local treatment. Ordinary douching is useless in the treatment of pathological leucorrhoea. The author states that after thorough cleansing of the vagina and cervix with liquid soap and warm water, followed by an alkaline ablation, the cervical canal should receive like treatment, a naturally small or a stenotic os being previously dilated. Cervical erosions and ulcerations may be treated by applications of solid silver nitrate, pure carbolic acid, or a 10 per cent. mixture of thymol iodide in cod-liver oil. Hypertrophy, hyperplasia, and granular ectropion of the cervix demand

bordering
vaginal walls may be relieved by the insertion of a hard rubber ring pessary. A vaginal tampon should be made of soft gauze, such as is produced by boiling a gauze bandage until starch-free and drying. Foss's method of packing the cervical canal, fornices, and upper vagina with gauze soaked in methylene-glycerin solution has given satisfactory results; the tampon is renewed daily for five days and followed by two dry packs. Alternatively, dry tampons, alternating with tampons soaked in a 5 per cent. solution of picric acid in 25 per cent. alcohol and left in situ for eight hours, may be used.

714. Air Embolus after Criminal Abortion.

ACCORDING to HORNUNG (*Zentralbl. f. Gynäk.*, April 16th, 1921) the occurrence of air embolus after attempts to induce criminal abortion is not very rare; fatal cases coming to autopsy have been described by Richter and others. The writer relates the case of a girl, aged 20, three months pregnant, who suddenly, after an eighth injection of soap and water, given through an indiarubber syringe with a rigid nozzle 12 cm. long, experienced air hunger and severe pain and lost consciousness; at the same time she became cyanosed, and brisk vaginal haemorrhage was noticed. Examination five hours later showed a penetrating wound producing a cervico-vesical fistula; the lips were still cyanotic, there were petechiae on both arms, and a small recent retinal haemorrhage was noted. The convalescence was apyrexial, and the patient was discharged on the eighteenth day with the fistula healed; abortion occurred two weeks later. The occurrence of petechial haemorrhages in the systemic circulation is susceptible of two explanations: (1) that the patient, in common with 25 per cent. of all individuals (according to Lubarsch) possessed a patent foramen ovale; (2) that bubbles of air had passed through the lung capillaries. That this can occur in experimental conditions was shown by Bichat, who injected hydrogen into the trachea and recovered an inflammable gas from a peripheral artery.

715. Caesarean Section in Acute Oedema of the Lungs.

STRAULI (*Schweiz. med. Woch.*, March 17th, 1921) discusses at some length the publications dealing with severe heart disease in relation to pregnancy. He contributes a case observed by himself in which, towards the end of pregnancy, severe endocarditis and mitral disease led to acute oedema of the lungs, with expectoration of much frothy bright red fluid. The patient was a primipara, aged 25, whose symptoms were so alarming that there seemed little prospect of recovery. She was very dyspnoeic, her face and lips were livid, and râles were audible all over the lungs. Within four hours of the onset of acute pulmonary oedema Caesarean section was performed in twenty-five minutes under light ether anaesthesia. At the end of the operation the patient looked better, and her lips were less cyanosed; in the evening of the same day she passed off, her lips were red, and her condition was satisfactory. She passed large quantities of urine during the next few days, oedema of the legs and lower abdomen subsiding simultaneously. To prevent recurrence of pregnancy both Fallopian tubes were resected under local anaesthesia about three weeks after the Caesarean section. When she reported herself some months later both she and her child were perfectly well, and she no longer suffered from swelling of the feet, palpitation of the heart, digestive disturbances, or other symptoms. The author regards this case as a cogent argument in favour of terminating pregnancy artificially as soon as pulmonary oedema and other manifestations of a disordered circulation become alarming.

PATHOLOGY.

716. Haemoglobinuria after a Second Blood Transfusion with Same Donor.

THALHIMER (*Journ. Amer. Med. Assoc.*, May 14th, 1921) reports the case of a boy who was transfused with his father's blood, a direct test of these bloods, made both by macroscopic and by microscopic methods, having previously detected no agglutinins. The transfusion was performed by the citrate method, and was followed by a mild febrile reaction only. Eighteen days later a similar transfusion was performed with the same donor, and after about 150 c.cm. had been given a most severe and unexpected reaction occurred. The transfusion was, of course, immediately stopped, and a few hours later the patient voided

very dark, haemoglobinuric urine; this showed that haemolysis had occurred, and explained the reaction. The cause of the intravascular haemolysis was also subsequently discovered. Two tests were overlooked in preparing for these transfusions. Had these been performed, another donor would have been selected, and the agglutinative and haemolytic phenomena would not have taken place. Yet on superficial examination it would seem that all the necessary precautions had been taken. A direct test of the bloods gave absolutely negative results. Lysins. This was further agglutination or haemolysis after the first transfusion. The success of this led to the omission of the tests before the second transfusion. It is known that in many instances repeated transfusions have been made with the same donor and recipient with no bad results. This case, together with some experimental transfusions in animals, demonstrates the necessity of performing tests before each transfusion, even though the same donor, who was previously satisfactory, is used. The two errors were: (1) In performing only direct tests on the two bloods and not also determining the blood groups; (2) in not repeating the direct tests before the second transfusion. Several weeks later the blood groups (Jansky nomenclature) showed the patient to belong to Group I and the donor (the patient's father) to Group III.

717. The Haemoclastic Crisis as Evidence of Hepatic Impairment.

FOSSATI and MAMONE (*Revista Sud Americana*, March 15th, 1921) record 21 cases in which they have applied the tests of the function of the hepatic cells described by Vidal, Abrami, and Lancovescio (*Comptes Rendus des Séances de l'Académie des Sciences*, July 12th, 1920). According to these authors, when there is impairment of hepatic cellular function the albumoses and peptones resulting from intestinal digestion and absorbed via the portal venous system are only in part metabolized in the liver; a portion not there intercepted reaches the systemic circulation, provoking a "peptone reaction," characterized especially by leucopenia, with relative diminution of lymphocytes, diminution of arterial pressure, and alteration of the coagulation time of the blood. This "haemoclastic reaction," occurring within three hours after administration (following a fast) of 200 grams of milk, is taken as evidence of impaired efficiency of the hepatic cell. Fossati and Mamone regard this as a test of great simplicity and precision, having considerable diagnostic value; its use may be of prognostic importance when surgical intervention is contemplated for affections of the liver or bile passages. The authors' tests showed that in normal individuals, or in a number of cases where the hepatic cells were unaffected (for example, cases of typhoid fever, gastric ulcer, cholecystitis), there ensued the ordinary digestive leucocytosis with relative lymphocytosis. On the other hand, in cases, for example, of early catarrhal jaundice, portal cirrhosis, or hepatic carcinoma, the haemoclastic reaction was well marked. A partial reaction, consisting in some leucopenia with relative lymphocytosis, was observed in a case of hypertrophic biliary cirrhosis and in one of chronic subicteroid malaria. The haemoclastic reaction was absent in three cases of cholelithiasis. Unlike Vidal, Abrami, and Lancovescio, the authors found the haemoclastic reaction absent as a rule in cases of chronic passive congestion of the liver consequent on heart disease. In estimating the reaction less importance is said to attach to blood pressure and blood coagulation measurements than to the blood count.

718. Experimental Transplantation of Fascia.

CHIRONI (*Il Policlinico, Sez. Chir.*, March 15th, 1921), as the results of experiments on dogs, came to the following conclusions: (1) Transplantation of free flaps of fascia which are thin and of small size undergo degeneration, with gradual substitution of newly formed connective tissue as the result of a proliferation of the connective tissue elements derived from the surrounding tissues and from the transplanted portion itself. (2) On the other hand, a portion of the fascia lata transplanted from the same animal retains its complete vitality and normal histological structure with the exception of small necrotic zones, probably due to transient circulatory disturbances. (3) The elastic fibres of the fascial tissue keep in a good state of preservation, and often increase in number without invading the surrounding tissues. (4) When the portion of fascia lata is required to functionate, it modifies the direction of its fibres according to the traction exerted on it.

INTRINSIC CANCER OF THE LARYNX:

USUAL SITE OF ORIGIN, AS DEMONSTRATED AT 50 LARYNGO-FISSURES, AND ITS INFLUENCE ON DIAGNOSIS, PROGNOSIS, AND TREATMENT.*

BY

SIR ST. CLAIR THOMSON,

PROFESSOR OF LARYNGOLOGY AND SURGEON FOR DISEASES OF THE THROAT, KING'S COLLEGE HOSPITAL, LONDON.

It has been well said by McBride that in investigations on cancer of the larynx, the "pearl of great price is early diagnosis, for upon this depends the curability of the fell disease."¹ I think it is evident that many of the failures which overtook early efforts at cure by laryngo-fissure were due to delayed diagnosis. Just as early diagnosis and improved technique have advanced, so has this operation progressed until it has succeeded in securing more lasting cures than can be claimed for cancer in any other internal region of the body. Earlier diagnosis has also led to a steady diminution of the number of cases for which complete laryngectomy is the only possibility.

Last year I gave the results of an investigation into impaired mobility of a cord as an indication in diagnosis and prognosis in intrinsic cancer of the larynx, showing that it was neither a necessary nor a frequent symptom, that it was only met with in a minority of cases, and that, though it was a valuable symptom when present, other signs must be relied on for an early diagnosis.²

This summer I submit a research on another point which has not been settled and has threatened to mislead us. I refer to the current view that malignant disease of the endolarynx is most commonly met with in the posterior third of the glottis.

Historical.

Fortunately, in our speciality, and in this country, we need not go very far back to discover a source of error. If we turn to Morell Mackenzie's *Textbook*, published in 1880, we can detect one source and, at the same time, appreciate the progress made in the study of laryngeal cancer in forty years. On page 338 he begins his description by saying that "pain, dyspnoea and dysphagia are generally present," symptoms which, nowadays, we can only regard as indicative of a late and generally inoperable stage of the disease. It is true that he says, later on, that hoarseness may be a very early symptom, and sometimes precedes all other symptoms by months or even years; but the much greater prominence he gives to hæmorrhage, fetor and cachexia would only mislead a present-day student. It is evident that he knew little of intrinsic cancer as we see and know it, possibly because forty years ago patients did not present themselves early for a persistent hoarseness, and even at the present day we know that medical men may fail to recognize the danger of delay in getting an expert opinion on a case of "mere huskiness." Mackenzie also misled a generation by stating (p. 336) that "the site of the tumour is in most cases one of the ventricular bands"; he even gives a table of 53 cases in which the cords only appear as the site of origin in 7 cases, and he points out that in 28 cases (or 56.7 per cent.) one of the ventricular bands was the first part affected.

By 1899 progress in diagnosis had been made, as shown by Lennox Browne's greater appreciation of the difference between extrinsic and intrinsic cancer, and his recognition of the fact that in the latter type "hoarseness is the earliest symptom of the disease and may have existed a very long time before advice will have been sought."³ But he also is mistaken when he writes that "enlarged experience convinces me that this form of cancer frequently commences in the ventricle." This teaching, in these two leading textbooks, was retarding progress.

Recent Views.

There can be little doubt that, as claimed by McBride,⁴ it was Semon who altered this view by showing from his experience that the intrinsic form of laryngeal cancer was more common than the extrinsic, and that the cords were "by far the most frequently affected parts." Semon recorded this as early as 1896⁵; it has been

confirmed by Schmiegelow, Chevalier Jackson and myself, and, doubtless, it is now admitted by all laryngologists. It was a great step forward. But, coming next to the consideration of which part of the cord is most frequently the site of origin, we see that Semon's independent observation was dimmed by the teaching of Virchow. He writes as follows: "Virchow has taught us that benign growths, if occurring on the vocal cords, have a tendency to localize themselves on their *front parts*, and very frequently on the anterior commissure of the vocal cords. If, on the other hand, you find a . . . growth on the *posterior parts* of a . . . if the patient be well advanced in ye . . . suspicious, and still more so if such a growth be located in the interarytenoid fold where benign growths practically never occur."

McBride, in summarizing Semon's teaching on this subject, gives as the first point of most importance, a "tumour which may be very minute, and, while it may be found in any part of the cord, is most commonly situated on the posterior third." I must confess that, like others, I accepted this teaching, and also McBride's statement, that Semon's observations "still remain the last important word which has been said on the diagnosis of early laryngeal cancer."⁶

Material and Methods.

The results of my own observations, which are now considerably larger than Semon's, will, I feel sure, demonstrate to your satisfaction that intrinsic cancer does not show a preference for the posterior part of the vocal cord, and that the interarytenoid region must be rarely affected—for I have never seen a case.

My conclusions are founded on 50 cases, in which the diagnosis was based not only on the appearances reflected in the laryngeal mirror, but also on the direct inspection of the disease when the larynx was opened by a laryngo-fissure. In addition, confirmation was sought in every instance by microscopic examination of the growth; the pathologist confirmed the clinical diagnosis in every case. I have never opened the larynx for epithelioma and found it to be anything else than cancer, although I have twice thought, at first, from clinical inspection that the disease was tuberculosis, but later on altered my diagnosis in time to secure a successful laryngo-fissure.

It will indicate the greater precision we are now able to arrive at in diagnosis if I recall that Grünwald, in 1907, recorded that out of 93 radical operations undertaken for the cure of what was supposed to be laryngeal cancer, the diagnosis was turned out to have been mistaken in no less than 17—that is, in nearly 20 per cent. Jobson Horne, about the same date, formed the opinion that tuberculous disease was not infrequently mistaken for epithelioma, as he had learned from the examination of tissues sent him after removal by the mouth, by laryngo-fissure, or even with the entire larynx.⁷

Statistics.

These 50 cases have been tabulated according to the invasion by the neoplasm of (a) the anterior third of the cord only, (b) the middle third only, (c) the posterior third only; or combined invasion of (d) the anterior and middle thirds, (e) the middle and posterior thirds; or (f) the whole cord. I have also the numbers of the cases where (g) the anterior commissure or (h) the posterior commissure was attacked, and, finally, the statistics as regards (i) the subglottic area.

The results, so far as figures can express them, are as follows:

TABLE A.—Intrinsic Cancer.

Site of invasion in 50 cases.			
(a) Anterior third only of cord	3 cases
(b) Middle third only of cord	7 "
(c) Posterior third only of cord	0 "
(d) Anterior and middle thirds of cord	16 "
(e) Middle and posterior thirds of cord	3 "
(f) Whole cord	21 "
			50

TABLE B.—Intrinsic Cancer.

Extension in 50 cases to—			
(g) Anterior commissure	6 cases
(h) Posterior commissure (that is, the interarytenoid region)	0 "
(i) Subglottic region	13 "

* A paper read before the Summer Congress of the Section of Laryngology, Royal Society of Medicine, London, June 2nd, 1921.

Putting it, as regards the cords, in another way, I find that the portion of cord invaded by the cancerous growth is as follows:

TABLE C.—*Intrinsic Cancer.*

Third of cord invaded in 50 cases.

Anterior third in	39 cases
Middle third in	47 "
Posterior third in	24 "

In no single case was the growth at operation found to grow from any other area surrounding the glottis except the vocal cords and subglottic region.

Subglottic Cancer.

To have found the growth in the subglottic area in 13 out of 50 cases may come as a surprise. I was not prepared to find it, or, at least, to have found it so extensive, in several cases. Neither direct nor indirect laryngoscopy will always reveal it, but we may be prepared to meet it when the mobility of the cord is interfered with, and particularly when that mobility is impaired out of proportion to the visible extent of the lesion. Another discovery has been that a subglottic growth is more common in the anterior than in the posterior segment of the larynx. The subglottic invasion was found in one case where the anterior third only of the cord was affected; in 6 cases where only the anterior and middle thirds were attacked; and in 6 cases where the whole cord was invaded. But even in these last 6 cases, I hasten to say, the subglottic part of the growth was much more marked anteriorly, and, in some, was limited to the anterior half of the subglottic area. Indeed, as will be presently shown by illustrations, the cancer, in certain cases, undoubtedly originated below the anterior half of the cord, which it only invaded slowly and after it had made, relatively speaking, considerable progress before causing any symptoms. Want of tension in one cord was, in some cases, the first and only sign. Immobility of the cord is much more common in the subglottic cases; thus, in the 13 cases, the cord was fixed in no less than 6—that is, in nearly half the cases. Whereas, in the remaining 37 cases impaired mobility was only noted in 11—that is, in about 30 per cent. of them.

Author's View.

We now see that these 50 cases—controlled by indirect laryngoscopy, by direct inspection at a laryngo-fissure and by histological examination—yield a conclusion which is in direct opposition to that of Virchow and Semon. In other words, intrinsic cancer of the larynx is much more apt to take its origin in the centre or anterior portion of the vocal cord, or in the anterior half of the subglottic area, than in the posterior third of the larynx.

Pathology.

It is interesting to note that this conclusion appears to me to confirm the previsions which Jobson Horne based on his histological and pathological investigations of the larynx. In 1893, and again in 1907, he pointed out that tuberculosis attacks, by preference, that area of the larynx which is covered with columnar epithelium and is richest in glandular structure; whereas epithelioma shows a preference for that part of the larynx which is clad with squamous epithelium and is relatively free from glands. The posterior half of the larynx supplies the former conditions; the anterior half, which I have just shown to be the favourite site of intrinsic cancer, is lined with pavement epithelium, and is almost void of glands.⁹

As regards prognosis in reference to the site of an intrinsic cancer, it need hardly be pointed out that growths found on the upper surface of the cord, and those of a projecting or even semi-pedunculated character, are the most favourable. The more limited the growth the better is the prospect of completely removing it with a good margin of healthy tissue all round—that is in front and behind, above and below the cord, and also in the depth away from the glottis and toward the thyroid ala. These conditions are most likely to be met with in a growth of the middle of the cord, or of the anterior two-thirds; fortunately, as a reference to my statistics will show, these are the most usual sites.

If the anterior commissure is invaded the prognosis is not quite so good, though complete extirpation can still be effected, although with some sacrifice of the anterior part

of the opposite cord. As the growth approaches the arytenoid region the prognosis becomes less promising, and if the arytenoid itself is undoubtedly invaded it is probable that a hemi-laryngectomy or complete laryngectomy is the more promising operation.

When an epithelioma originates on the inner—that is, the glottic—surface of the cord the prognosis becomes less favourable, partly because there is lymphatic tissue in this area into which the cancer cells spread more rapidly than they do into the elastic tissue of the cord itself, and partly because the growth is already fairly extensive before it has appeared on the surface of the cord in sufficient amount to cause noticeable hoarseness and to be recognized clinically. Doubtless it is for these same two reasons that subglottic cancer is even more unpromising, and also because, as it dips down inside the crico-thyroid membrane, it is less circumscribed than when it lies entirely within the limiting barrier of the thyroid ala. In two cases I had to divide the cricoid cartilage to get below the downward extension of a subglottic epithelioma.

This darker prognosis with subglottic growths is confirmed by a reference to my 13 such cases: 7, or more than 50 per cent. of them, have died of recurrence. It is also striking to note that of these 13 cases the mobility of the cord was impaired or abolished in no less than 6, and that 4 out of the 6 are amongst the recurrences. This confirms the conclusion I enunciated in my paper of a year ago—namely, that impaired mobility of a cord is an unfavourable symptom.¹⁰

Treatment.

As the naked eye is not sufficiently trustworthy as a judge of the extent of an infiltrating growth, the entire cord should always be removed. Thus in one of my cases (No. 25) the pathologist reported that "the growth appears to be in the anterior part of the cord and to have burrowed backwards in the tissues beneath the surface epithelium, which is still intact over a considerable area of the growth." (The patient remains free from recurrence at the age of 77, five years after operation.) In a subglottic case (No. 24) the report of the pathologist was: "Specimen presented a deeply ulcerated new growth in subglottic region, immediately beneath the left vocal cord. A typical epithelioma. Though the growth arises beneath the cord, and the actual mucous membrane of the cord is still intact, the growth has invaded the substance of the cord beneath the mucosa." (The patient died of recurrence.)

CONCLUSIONS.

As Regards Usual Site of Origin.

1. Intrinsic cancer of the larynx originates on the vocal cords or in the subglottic area.
2. It has never been found in the posterior commissure (interarytenoid region), nor originating from the ventricular bands or the ventricle of Morgagni in 50 cases carefully examined both indirectly with the mirror and by direct inspection after splitting the larynx.
3. A malignant growth may originate on any part of a cord, but is more common in the central portion or anterior half than in the posterior area of the larynx.
4. As is now well known, an epithelioma originating in this region remains for a long time limited to the cord affected and the adjoining side of the larynx, but it may cross the anterior commissure, and, in later stages, it invades the arytenoid and the area to the outer side of it.
5. The inner surface of the cord may be affected primarily or by extension. The subglottic area may be invaded by a growth originating in a cord. But a cancer may also start below the level of the cords, in the subglottic area.
6. A subglottic cancer is much more common in the anterior than in the posterior half of the larynx.

As Regards Prognosis.

1. The superficial or projecting tumours of limited extent are the most favourable.
2. Those situated in the middle third or anterior half of the cord are more promising than those invading the anterior commissure in front or the arytenoid region behind.
3. Growths embedded in a cord, or extending into it below an intact mucosa are not so favourable.
4. An epithelioma extending along the inner margin of a cord is still less favourable.

5. Subglottic cancers are very unpromising as regards lasting cure by laryngo-fissure. They are frequently associated with impaired mobility or complete fixation of a cord.

As Regards Operation.

1. In every case, however limited the growth, the entire vocal cord should be excised from the anterior commissure up to and including the vocal process of the arytenoid.

2. The growth, with as wide a margin as possible of apparently healthy tissue all round it, should be removed in one mass; the excision should therefore go down to the lower edge of the subglottic area; above, it should pass through the healthy ventricular band; and externally it must include the perichondrium lining the thyroid ala.

3. To facilitate this the thyroid ala should be removed so that a laryngo-fissure is really a partial hemilaryngectomy.

HAEMATURIA AS SEEN BY THE SURGEON.

ANDREW FULLERTON, C.B., C.M.G., F.R.C.S.I.,

SURGEON, ROYAL VICTORIA HOSPITAL, LIVERPOOL, AND DEPUTY HOSPITAL FOR SICK CHILDREN.

THERE are certain general rules laid down by clinicians to enable the practitioner to make a shrewd guess as to the cause and origin of haematuria in a given case. These rules are useful, but, as I shall show, they cannot always be relied upon for accurate diagnosis.

The cystoscope, combined in many cases with radiography, is indispensable for the examination of cases of haematuria from kidney, meter, bladder, or prostate, and the urethroscope for doubtful cases of urethral haemorrhage. Indiscriminate enthusiasm, however, must be deprecated. A cystoscope or a urethroscope is not to be used in every patient who complains of urinary symptoms. The cystoscope may prove to be a dangerous weapon in certain cases of tubercle, malignant disease, enlarged prostate, sepsis, and incipient or established anaemia. It is well to proceed as far as possible along the ordinary lines towards diagnosis. The cystoscope or urethroscope may then be used to complete the examination.

General Considerations.

When blood is intimately mixed with the urine it is probable that the source of the haemorrhage is the kidney. This rule is not absolute. All we can say with certainty is that the blood is shed in small or moderate quantity, allowing intimate mixture with the urine before clotting has had time to take place. The cystoscope in a renal case may show a red efflux, the smoky or dark colour of the voided specimen being due to the change of oxyhaemoglobin into methaemoglobin by admixture with the acid urine. The following cases exemplify the difficulties of diagnosis:

A male, aged 56, presented himself with haematuria. The specimen passed was dark in colour. The only other symptom was frequency of micturition. Cystoscopy showed a malignant ulcer on the base of the bladder.

A man, aged 74, complained of difficulty and frequency of micturition, especially at night. The stream was small and the urine dark red; no clots were present. Instead of the expected enlarged prostate the cystoscope showed renal haematuria from the left side.

A clergyman, aged 55, stated that after a chill in 1919 he passed blood intimately mixed with the urine. He passed no clots, had no pain nor any dysuria. He had intervals of freedom with clear urine; later, tiny clots began to appear. The symptoms suggested haematuria of renal origin. Cystoscopy showed a papilloma on the right lateral wall of the bladder.

I could multiply cases to show the fallacy of depending for a diagnosis upon the character of the urine alone.

The presence of frequency of micturition is strongly suggestive that the site of the haematuria is the bladder or prostate; but the second case just mentioned, in which the haemorrhage came from the left kidney, shows how little dependence can be placed on this symptom. Frequency and bleeding in an old man will at once suggest enlarged prostate. The bleeding, as in the case just mentioned, may be from the kidney, or it may be from an unsuspected tumour, as in the case of a man, aged 70, who had symptoms of enlarged prostate. About a month before I saw him he had haematuria with clots and complete retention. Operation discovered not only an enlarged prostate but a papilloma as well. The haematuria was due to the papilloma and his other symptoms to the enlarged prostate.

If frequency of micturition and haematuria are combined with pain in the glans, penis, scalding, and urgency, and if, in addition, pus and mucus are present, the diagnosis of cystitis is justified, but malignant growths and calculus must be excluded by direct observation.

Pain in the lumbar region, whether or not it culminates in renal colic, suggests an affection of the renal region of that side, but our expectations were belied in the case of a man, aged 49 years, who had haematuria with left lumbar pain. The cystoscope showed blood issuing from the right ureteral orifice.

If the haematuria is initial—that is, at the beginning of micturition—it comes, probably, from the prostatic urethra, or possibly from the anterior urethra. Blood issuing from the urethra, independently of micturition, comes from a source distal to the compressor urethrae. A small quantity may lie in the urethra and form a cast of the canal, which is swept out by the next act of micturition. Haematuria with massive clotting is often of bladder origin. During the late war, however, one of the most formidable complications of gunshot wounds of the kidney was secondary haemorrhage, and in some of the cases blood was poured out in such quantity that the bladder was distended by large clots difficult to evacuate. In civil injuries of the kidney produced by crushes or strains, clots may form in the bladder. Again, in tumours of the kidney large clots may be passed, as in the case of a man aged 53, who complained that he passed numerous blood clots, about the thickness of the little finger. Cystoscopy showed blood issuing from the right ureteral orifice. Operation revealed a hypernephroma of the right kidney.

The size and shape of the clots may be of assistance in diagnosis. A long cast of the ureter is sometimes passed. Its length and thickness indicate its origin. More frequently shorter lengths are passed. Casts formed in the urethra are thicker and often show constrictions corresponding to those normally present in this canal.

Microscopical examination of the urine, especially if it can be carried out in the intervals between the attacks of bleeding, may be helpful. Mention need only be made of the presence of renal casts, cells from the bladder, ureter, or kidney, portions of tumour, pus cells, crystals, micro-organisms, etc.

In the accompanying table I have grouped my cases according to the region affected; under each heading they are arranged in order of frequency. This has many disadvantages, but is convenient for my present purpose.

CASES OF HAEMATURIA.

Kidney.	Cases.
Tubercle of kidney (generally involving bladder secondarily) ...	103
Symptomless renal haematuria ...	47
Renal calculus ...	44
... is and cystitis combined	32
... cysts ...	21
Injury to kidney (excluding war injuries) ...	19
Renal colic (cause?) ...	7
Hydronephrosis ...	5
Pyonephrosis ...	4
Movable kidney ...	4
Horseshoe kidney ...	3
Oxaluria ...	3
Hemochia purpura ...	2
Accessory renal artery ...	1

Ureter.

Ureteral calculus ...	9
Injury to ureter (excluding war injuries) ...	1

AFFECTIONS OF THE KIDNEY.

Tubercle of the Kidney.

Tuberculosis of the urinary tract is very common in the North of Ireland. Nearly 10 per cent. of all cases cystoscoped by me had urinary tuberculosis, and in 75 per cent. of these haematuria was present. In the overwhelming majority the primary focus, as far as the urinary tract was concerned, was the kidney. In my experience tuberculosis of the bladder, arising secondarily to deposits in the epididymis and testicle, is comparatively rare. If the ureteral catheter is used in all cases of tuberculosis of the epididymis the surgeon will be surprised to find how often the kidney is affected. I have seen tuberculosis of the epididymis make its appearance three months after the removal of a tuberculous kidney on the same side, and I have under my care at present a patient from whom I removed a tuberculous kidney, who has tuberculosis of the epididymis on both sides. While in France I saw, with Major Santos of the Portuguese army, a case in which the right kidney and ureter, the bladder, the prostate, the seminal vesicles and the urethra, including the meatus externus, were all infected with tubercle. Primary tuberculosis of the bladder, if it occurs at all, is so rare that such a diagnosis should not be made except after the most careful examination of all parts of the urinary tract.

The character of the haematuria in most cases of tuberculosis of the urinary tract resembles that found in bad cases of cystitis. The blood comes for the most part from ulcers on the bladder wall. Severe haematuria from the kidney is not, in my experience, frequent, but in the following case the blood was probably of renal origin:

A man, aged 27, first noticed blood ten years ago; it was not accompanied by any other symptoms and lasted for a week. He remained well for five years, when blood again appeared, accompanied this time by pain in the right lumbar region. Three years later he noticed a lump about the size of a pea behind the left testicle. Two years ago irritability of the bladder made its appearance. In January, 1920, I removed a tuberculous right kidney. The left epididymis was at this time hard and nodular, and the vas thickened. Both epididymides are now affected and there is a discharging sinus on both sides. This case has already been referred to.

Symptomless Renal Haematuria.

I have seen 47 cases of renal haematuria in which it was the only symptom of disease except for some renal colic in a few, due, no doubt, to the passage of small clots down the ureter. Some of these cases of symptomless renal haematuria have already perhaps proved, or may in the future declare themselves to be tumours, stones, tubercle, or other demonstrable affection of the kidney, but many will doubtless remain under the heading of what is known as renal epis taxis, renal haemophilia, essential renal haematuria, or symptomless renal haematuria. The haemorrhage in these cases is more or less severe, more or less persistent, and is seen to issue from one ureter. There are intervals of freedom in which the urine shows no departure from the normal. The patient may be otherwise in fair or even good condition, and the haematuria may persist for years without any serious impairment of the health. The bleeding is unilateral. No gross changes in the kidney can be found to account for it. Various hypotheses have been advanced to explain its occurrence. It

has been attributed to passive congestion, circumscribed or diffuse fibrous changes, disturbances of the vasomotor and sensory nerves, multiple microscopic calculi of the papillae, chronic microbic infections, nephritis, etc. The following case will exemplify the difficulties of diagnosis:

A gentleman, aged 42, noticed, about ten days before I saw him, that his urine was bloodstained. There was no pain, except, perhaps, a slight uneasiness in the left side. The urine was dark in colour, and there were no clots, no pus, and no sugar. Both kidneys were easily palpable. Blood was seen to issue from the left ureter. The specimen obtained from the right side was normal in all respects. Shortly after this tubercle bacilli were found in the sputum, and the patient was sent to a sanatorium for some months. He remained free from bleeding for some years. In the summer of 1919 haematuria again appeared, and he passed occasional small clots. No enlargement of either kidney was found. The urine was free from tubercle bacilli, and casts were absent. X-ray examination was negative. The bleeding stopped, and he remained clear for nearly a year. It recurred in July, 1920, and continued till October. I then injected 10 c.cm. of 5 per cent. solution of nitrate of silver into the pelvis of the affected kidney, some of which immediately escaped into the bladder. The bleeding increased for a few days and then ceased. He remained well for a month, when another recurrence took place. The complication of tubercle bacilli in the sputum raised suspicions of tuberculosis of the kidney, but no sign of this has developed during the seven years I have had him under observation.

The following case is one of the most interesting I have seen:

A sailor, aged 30, two months after a fall on his right side on board ship, noticed that his urine was smoky. Professor Rovsing of Copenhagen found blood issuing from the right ureter. X-ray examination was negative. The right kidney was explored and nothing but adhesions to surrounding parts was found. The bleeding continued for three weeks and then cleared up for a few days to recur again for a week. Again it cleared up for three or four weeks and once again it recurred. On my examination the blood was seen to come from the left side. The specimen obtained from the side operated on by Professor Rovsing was absolutely normal. Three years later I again cystoscoped this patient, who had been bleeding off and on since my first examination. The blood was now coming from the right side.

Renal Calculus.

In 44 cases of renal calculus, out of 61 examined, the presence of blood was noted. The two cardinal signs of renal calculus are renal colic and haematuria, one or other or both of which may be entirely absent. Vomiting is also frequently present. In these days radiography will detect the smallest calculus, but in my earlier work, especially in the country, I had to depend on other methods for diagnosis. A history of renal colic with or without blood, the presence of pus, the presence of albumin, and a unilateral diuresis with a diminution of the specific gravity of the urine on the affected side afforded strong presumptive evidence upon which I often operated for stone. I should now be loath to operate without an x-ray examination. The symptoms of renal calculus are sometimes closely simulated by tuberculosis of the kidney, new growths, hydronephrosis, pyonephrosis, the presence of an accessory renal artery, hydatid cysts, and what I can only describe as ureteral spasm. I have often caused typical renal colic of a temporary character by the use of the ureteral catheter, and I have at least on one occasion relieved a patient by the mere passage of the same.

Pyelitis.

The essential feature of pyelitis is the presence of pus in the urine on one or both sides. The most usual cause is the *Bacillus coli communis*, but I have seen staphylococci, streptococci, and other organisms. Though severe haemorrhage may occur, the amount of blood present in my cases has been, as a rule, small, and not a dominant feature in the clinical picture. In acute cases the temperature is raised, and it is unwise to carry out any instrumental examination. After such an examination the temperature is likely to shoot up, and rigors may occur. Every case of pyelitis should be x-rayed. I have seen a patient treated by vaccines for months for persistent pyuria due to a stone in the pelvis of the kidney.

Renal Tumours and Cysts.

Under this heading there were 21 cases, including the following: Hypernephroma, by far the most numerous; malignant adenoma, sarcoma, malignant growths of the

abdomen involving the kidney by continuity, a case of hydratid cyst which I saw in France, congenital cystic kidney, a rare form of cystic kidney removed from a child aged 2 years, and one or two cases judged to be inoperable. In the space at my disposal I can only deal in a general way with this group. In the case of hydratid cysts and the cystic kidney removed from the child aged 2 years, the bleeding, though noticeable, was neither persistent nor serious. In a case of congenital cystic kidney the bleeding was so profuse as to threaten the life of the patient; as is well known, this type of tumour is nearly always bilateral, and it is therefore useless to remove one kidney.

In a case of sarcoma of the kidney the patient, a female child aged 3 years and 3 months, had severe haematuria, and screamed with pain on passing water, no doubt owing to the clots present in the bladder. Cystoscopy confirmed the diagnosis of haemorrhage from a tumour of the left kidney. A few days later I removed a sarcomatous kidney by the transperitoneal route. The patient died four months later from recurrence.

A man, aged 53, gave a history of having passed a stone after "terrible" renal colic. Twelve years later he presented himself with an indistinct swelling in the side previously affected with renal colic. In the previous illness he had had haematuria of slight degree. The urine was free from blood when I saw him for the swelling in the loin. I expected to find a stone in the pelvis of the kidney from the history, and also from the cystoscopic examination, which showed a diminished specific gravity in the specimen from the affected side. Operation revealed a malignant adenoma of the kidney.

In several of the cases of hypernephroma the bleeding was considerable and clots were passed. Some of them suffered from renal colic, and others had no other symptom but painless haematuria, at any rate in the early stages.

In cases of tumour of the kidney the earliest symptom may be a type of painless haematuria exactly similar to that described as "essential renal haematuria." I am not sure that every case of renal haematuria of doubtful origin should not be explored to avoid missing an early case of malignant disease. Many unnecessary operations would doubtless be performed, but some cases of tumour would be diagnosed in time to admit of successful removal with less chance of recurrence. The appearance of a tumour in the side shows that the disease is in an advanced stage. Radiography and pyelography may show earlier some alteration in the size or contour of the kidney, or in the pelvic shadow, and ought always to be resorted to in a doubtful case.

Nephritis.

I have examined 19 of these cases suffering from haematuria. In all, some other sign or symptom was present, such as casts in the urine, albumin when the bleeding was for the moment absent, cardio-vascular changes, albuminuric retinitis, oedema of the face and extremities, or some other indication of acute or chronic nephritis. These cases belong to the domain of the physician rather than that of the surgeon. Their chief feature, from a cystoscopic point of view, is the presence of blood on both sides. In 11 of my series this was the case. One of them was a case of trench nephritis, in another with severe renal colic and unilateral haematuria the late Dr. McQuitty made the diagnosis from the discovery of albuminuric retinitis. Some of these cases have cleared up completely.

Injury to the Kidney.

Besides the 56 cases of gunshot wounds of the kidney, fully reported elsewhere, I have seen in civil practice 7 cases sufficiently mild to admit of cystoscopic examination. A comparatively slight strain is sometimes sufficient to injure the kidney and give rise to considerable haematuria. I have seen this occur in a patient who slipped on a plank and apparently bruised his kidney in the effort to right himself. With more severe injuries the presence of a perirenal haematoma, as in gunshot wounds of the kidney, is an outstanding feature and a help in diagnosis.

A young man, aged 18, was seen with Dr. Mann, of Dunganon. He fell across a drain, his shoulders resting on one bank and his feet on the other, so as to produce lateral flexion of the body, with the convexity to the right side. That the kidney on this side was injured was evident from haematuria with clots, a perirenal haematoma and pain. Cystoscopy showed blood issuing from the right ureteral orifice. Recovery without operation took place. In this case the kidney was probably crushed between the ribs and the ilium on the concave side.

It is important to know when to intervene in cases of renal injury. It is almost certainly fatal to operate on a blanched patient. Blood transfusion, followed by immediate operation, saved lives during the late war.

Renal Colic without Obvious Cause.

In the 5 cases of this nature that I have seen the colic strongly suggested stone, but radiography failed to show any abnormal shadow. It may be, as Casper suggests, that spasm of the ureter occurs comparable to that of the oesophagus in hysterical people. In such cases the passage of the ureteral catheter might be tried, as in the case already mentioned.

Hydronephrosis.

Haematuria is not a cardinal sign of hydronephrosis, though it may be present. The chief signs and symptoms of this condition are pain, sometimes developing into renal colic with vomiting, and a tumour in the lumbar region which varies in size or even disappears altogether at times. The urine obtained from the affected side is of low specific gravity compared with that of the sound side. At times no fluid can be obtained owing to the block causing the hydronephrosis. In one case inspissated blood was seen by the cystoscope to be squeezed out from the ureter of the affected side like ointment from a tube. Bleeding had evidently taken place at some time into the sac of the distended kidney. By injecting opaque solution like thorium nitrate or collargol into the pelvis of the kidney, and taking an x-ray photograph, the shape and the size of the pelvis of the kidney and its branches may be determined. If the cavity is large the opaque fluid may be so diluted that no definite shadow is seen.

Pyonephrosis.

The allied condition of pyonephrosis, of which I have had 4 cases giving a history of haematuria, is often diagnosed by the profuse discharge of pus which takes place at intervals from the distended kidney into the bladder.

In a case seen recently the urine had been clear and pronounced normal by our pathological department at the Royal Victoria Hospital. On cystoscopic examination I could detect no change in the ureter of the affected side, but on passing a ureteral catheter some way up clouds of pus were discharged by the side of the catheter into the bladder. The patient had suffered from severe attacks of renal colic. In the calyces of the distended kidney on removal a mixture of inspissated pus and blood was seen, and the colic may have been due to portions of this being passed along the ureter from time to time.

Movable Kidney.

It is well known that during Dietl's crises haematuria may occur, but I have only had 3 cases of movable kidney with haematuria sent to me for cystoscopic examination. In the first case, although the kidney was movable, pain was slight or absent. The specific gravity of the urine on the affected side was 1015, as against 1020 on the sound side. Blood was present in the jets from the affected side. Nephropexy cured the haematuria. In the second case the specific gravity was again lower on the affected side. The patient suffered from Dietl's crises. The late Dr. Hicks found the kidney surrounded by peritoneum which formed a mesentery for it. In the third case crises were present and there was considerable haematuria.

Horseshoe Kidney.

In 2 cases an exploration showed a horseshoe kidney. In the first there was a connecting band across the middle line between the lower poles of the kidneys. In the second case, which was under the care of Mr. Mitchell, I have no further note than that a horseshoe kidney was found. The symptoms in these cases resembled those of movable kidney, and were due, no doubt, to malposition of the organ with kinking of ureter or vessels.

Oxaluria.

Haematuria due to oxaluria is usually dealt with by the physician, but I have cystoscoped 2 cases in which the symptoms were attributed to the presence of numerous crystals of calcium oxalate in the urine. In one of these severe renal colic was complained of, but no stone was found on operation.

Henoch's Purpura.

I have cystoscoped one case of this affection. In addition to haematuria there were ecchymotic spots on the body, arms and legs, particularly about the joints. Haematemesis was present and moderate pyrexia. On cystoscopy blood-stained fluid was seen issuing from both ureters. The urine contained blood casts and granular casts.

Accessory Renal Artery.

I have published two cases of hydronephrosis due to this condition.³ In these no blood was found in the urine. I have, however, seen one other case in which haematuria was present, due, apparently, to the presence of an abnormal artery passing across the ureter to the lower pole of the kidney, "bow-stringing" the ureter, as Mr. Fenwick says, near its junction with the pelvis of the kidney.

AFFECTIONS OF THE URETER.

Ureteral Calculus.

In nine cases haematuria was due to ureteral calculus, which at the time of examination was arrested or actually impacted in the ureter. The symptoms resemble those of renal or vesical calculi, and are diagnosed by x ray with the opaque ureteral catheter in position. Stereoscopic radiograms should be taken, as shadows crossed by that of the opaque catheter may be in a different plane and altogether outside the region of the ureter. I adopt the method I suggested in France for locating foreign bodies in the neighbourhood of the kidney and ureter.⁴

Injury to Ureter.

In civil practice I have seen one case of injury to the ureter; it was caused by a fracture of the pelvis. I have published details of four cases seen during the war and caused by gunshot wounds. The haematuria is not, as a rule, serious. The most important diagnostic sign is urinary fistula in gunshot wounds and extravasation in the line of the ureter in civil wounds. I have used collargol injections with x ray to localize the lesions and assist in the diagnosis of these cases. The method has already been published in detail.⁵

AFFECTIONS OF THE BLADDER.

Cystitis.

Haematuria was found in 113 cases of cystitis. In all it was moderate, and was often only discovered on microscopical examination. When visible it was generally of the terminal type, occurring at the end of micturition in the form of a few drops of blood with the last drops of urine. In some cases, and especially in those known as haemorrhagic cystitis, blood was mixed with the main part of the urine, although more pronounced in the last portion. During the war we became familiar with the haemorrhagic type of cystitis, with ecchymoses scattered over the mucous membrane.¹ In several of these cases streptococci were found. In ordinary circumstances, however, the most frequent organism was the *Bacillus coli communis*. Less frequent were staphylococci, *B. proteus*, gonococci, etc. In many cases, however, no bacteriological examination was made. I am not able to state definitely that in all of these cases the kidneys were free from infection. Cystitis is often due to a descending infection from the kidney. I have investigated a number of cases of cystitis which did not clear up with the ordinary methods of treatment, and in 17 pyelitis was present. These are included under the heading of pyelitis.

Tumours of the Bladder.

Some of the most severe cases of haematuria met with were due to tumours of the bladder. I have notes of 72 cases, and in most of them the haemorrhage is described as severe and associated with the formation of massive clots in the bladder. In some cases, however, the haemorrhage was trifling—at any rate, in the earlier stages.

A man, aged 38, complained of frequency of micturition and pain at the point of the penis. A little blood was passed on straining, and occasionally the act of micturition was suddenly arrested. These symptoms were strongly suggestive of stone. On passing the cystoscope, a pint of residual urine was drawn off. A small papilloma was seen to hang down over the vesical orifice of the urethra, suspended by a long pedicle. This acted as a ball valve, obstructing the flow of urine, and explained the patient's symptoms. The tumour was removed by suprapubic cystotomy.

A man, aged 54, noticed blood in his urine and slight pain in the left groin. He had some frequency of micturition during the day, but was not disturbed at night. There was also some pain at the point of the penis. The urine contained blood, but no pus. The cystoscope showed two small papillomata on the base of the bladder. These were removed by the high frequency current.

In other cases the bleeding was much more profuse, with much clotting, and in many there were multiple papillomata, extending all over the bladder. In the malignant cases sloughing of the free surface of the tumour and cystitis are more apt to occur, and the symptoms are correspondingly more severe.

The following case is so remarkable that I cannot refrain from mentioning it:

A woman, aged 51, had had the left breast removed for cancer about a year and a half before the present illness. She complained of blood in the urine; it was intimately mixed with the urine. There was a little frequency but no pain in the bladder region. There was some pain in the back, extending down the left leg. Cystoscopy showed at the apex of the bladder a sharply circumscribed circular ulcer about the size of a sixpenny-piece. The adjoining walls were drawn in folds towards the ulcerated area. Mr. Kirk operated and found an ulcer corresponding to the cystoscopic picture. The peritoneal aspect of the bladder was involved for an area rather smaller than the mucous membrane. Microscopically the ulcer proved to be scirrhus. In this case it is probable that cancer cells had dropped from the falciform ligament of the liver and taken root on the peritoneal aspect of the bladder.

The following case of fibromyoma is interesting owing to its extreme rarity:

A woman, aged 43, suffered from frequency with pain during micturition and haematuria with occasional clots. On cystoscopic examination I found a rounded projection on the right side about the size of a Tangerine orange; it was covered with normal mucous membrane, except at the inner edge where what looked like minute papillomata, or possibly mucous cysts, could be seen. I took the view that some growth in the pelvis was pushing the bladder wall inward, and referred the patient to a gynaecologist. Dr. Lowry found fibroids of the uterus, and a fibromyoma in the wall of the bladder quite free from the uterus.

The case of rhabdomyosarcoma is also interesting because very uncommon:

The patient had symptoms of cystitis for about a year. Cystoscopic examination showed on the base of the bladder, between the ureteral orifices, an ulcerated area covered with a whitish thick shreddy slough. The bladder was opened by the transvaginal route and a hardish ulcer, about half an inch in diameter, was excised. The excised area included the mouths of both ureters. Professor Symmers pronounced the ulcer to be malignant, a rhabdomyosarcoma showing muscle fibres with striations (lethal type). Also some cells round vessels (perithelioma). I examined the patient a year and a half later; the ureteric orifices were wide open, and the growth had not recurred.

Vesical Calculus.

Out of 46 cases of vesical calculus examined the presence of blood is mentioned in 34. This varied from a microscopical to a moderate degree of haemorrhage. The bleeding generally occurred at the end of micturition. The signs of stone in the bladder are sometimes obscure and the calculus is occasionally only accidentally discovered. Cases of severe cystitis are often labelled stone, and the symptoms are very similar. As a matter of fact, the symptoms of stone are due in a large measure to the cystitis which generally accompanies it. Sudden cessation of the stream is not diagnostic of stone. In cystitis spasm may occur at the neck of the bladder and the stream may be arrested, and in certain cases of stone this symptom may be entirely absent. Pain at the point of the penis is not confined to stone. It is present in cystitis. X-ray examination will detect a calculus, but I have seen a shadow in the pelvis diagnosed as stone which proved to be extravasical, and probably due to a deposit of tubercle in the ovary or broad ligament. Sir Almoth Wright asked me to see this case in France. The radiographer of the Harvard Unit had diagnosed a stone in the bladder. I could not find it on cystoscopic examination, but bimanually I could feel a hard mass in the pelvis. I subsequently removed a tuberculous kidney in this patient. The sound will detect most cases of stone, but the only satisfactory method is cystoscopy.

Ulceration of the Bladder.

Ulceration of the bladder is seen most frequently in tubercle of that organ and in malignant disease. Superficial ulceration is sometimes seen in cystitis. I have had

one case of extensive ulceration in which the mucous membrane of about a sixth part of the bladder sloughed, leaving the muscular coat exposed. This was attributed to mercury perchloride solution used to wash out the bladder, but it may have been due to an infection. Unfortunately a bacteriological examination was not made. The haematuria in the ten cases of ulceration of the bladder not due to tubercle or malignant disease, mentioned in the notes, was of a moderate character.

Rupture of Bladder Vessels.

The vessels of the mucous membrane of the healthy bladder very rarely rupture. In a few cases severe straining appears to be capable of causing this accident. I have had four cases in which such rupture had apparently taken place. One of these occurred in a case of retroverted uterus.

Bilharzia haematobia.

I have only cystoscoped two cases of bilharziasis of the bladder; both occurred in soldiers lately returned from the South African war. In the first case the symptoms came on nine months after the patient reached South Africa; he noticed a little blood at the end of micturition, but he had no other urinary symptoms. The urine was examined by Professor Symmers, who found the characteristic ova. The following appearances were seen with the cystoscope: The mucous membrane in places was dull red, thick and raised. Scattered over it were small raised white nodules, varying in size from that of a pin's head to that of a hemp seed. The little white bodies resembled pustular acne spots on the face. Small breaches of surface and haemorrhagic patches in the neighbourhood of these nodules were seen in some places. The appearances in the second case were somewhat similar.

Injury to the Bladder.

Injuries of the bladder are not infrequent in cases of fractured pelvis in civil life, but I have only cystoscoped one such case:

The patient was a railway porter who had been caught between a railway carriage and the platform. On admission to hospital he passed blood. The abdomen had been explored for ruptured bladder. There was some subperitoneal extravasation of blood on the left side of the bladder, but the peritoneum was not torn. Portions of the bowel and omentum were ecchylosed. The patient was cystoscoped a fortnight after his injury. There were a good many clots in the bladder. Several dark coloured rents were seen in the left wall. The mucous membrane at the edges of these rents was pale, almost dead white. The rents gaped slightly. While I was examining the patient a gush of ured the view. This may have understood that Mr. Kirk later

AFFECTIONS OF THE PROSTATE AND URETHRA.

Enlarged Prostate: Prostatitis.

In some cases of enlarged prostate the haematuria is due to associated cystitis. The haematuria in these is similar to that described under the heading "cystitis." More important from the point of view of treatment is haemorrhage from the vessels of the prostate itself, or of the mucous membrane covering its projection into the bladder. This may be so severe as to fill the bladder with clots, which block the internal meatus and the eye of the catheter used for the relief of retention. The practitioner is in a difficulty when confronted with such a case. A specially constructed catheter, which can be opened at the tip, when the latter has entered the bladder and been pushed up to a region free of the clots, may be used, or it may be necessary to perform cystotomy, or even to remove the prostate as an emergency operation if the patient's condition is otherwise favourable.

The haemorrhage in the cases of prostatic abscess was not of great significance. In the prostatitis case the blood was seen in the seminal fluid after emission.

Papillomata of the Urethra.

I have notes of two cases of severe bleeding from papillomata of the urethra. In the first the bleeding was profuse and independent of micturition. Its source was detected by the urethroscope after the injection of adrenaline. Three or four small papillomata, each about

the size of a corker pin's head, were seen 2 in. from the external meatus at a somewhat narrowed part of the urethra. Just behind this a large calibic stricture was seen. The papillomata were removed by a sharp cautery, and the raw area was touched with a strong solution of nitrate of silver. The bladder, curiously enough, was full of blood, which had apparently passed back through a relaxed sphincter. On washing out, the bladder and urethral orifices were seen to be healthy. The second case was almost exactly similar. The papillomata were removed by urethral forceps and the canal was packed for a few hours with strips of gauze.

Stone Impacted in the Urethra.

There were two cases of impacted stone in the present series. In the first the stone was situated just inside the meatus externus, and was easily removed. In the second the stone was detected in the prostatic urethra by the urethroscope. It was pushed back into the bladder and removed by litholapaxy. The bleeding in both these cases was trifling.

TREATMENT.

In cases of any severity the patient should be kept at rest, and morphine, if not contraindicated, should be administered. Calcium chloride or lactate should be given for a few days. Preparations of ergot and hazelue may be tried, and sterilized horse serum, or inhalations of CO₂, as recommended by Wright, may be of use in some cases. The underlying cause, if discoverable, will, of course, require attention. Tumours calcenli, tuberculous kidney, etc., demand surgical treatment in suitable cases. The bleeding in cystitis itself will be dealt with by urinary antiseptics and lavage of the bladder. Renal haematoma of the type known as "essential" may tax the resources of the surgeon to the utmost. Section of the kidney decapsulation, fixation of a movable kidney, incision into the pelvis, with direct attack on the papillae, etc., and injection of silver nitrate solution or adrenalin, are among the methods used. Removal of the offending organ is a radical procedure, only justifiable if all other methods fail and the patient's life is in danger. To control haemorrhage of bladder origin, pending more radical measures, adrenalin may be employed. A slower but more lasting remedy is to irrigate with silver nitrate solution. Failing this, the bladder may have to be opened and the cause dealt with, or, if that is not feasible, a large tube may be inserted and irrigation with hot water carried out. In certain cases of haemorrhage into the bladder, with massive clotting, an evacuating catheter similar to that used for litholapaxy may be used to remove the clots. It may even be necessary to perform cystotomy to clear out the clots. Packing the bladder is an unsatisfactory proceeding. If resorted to, a way of escape must be provided for the urine, and the urethral orifices must not be blocked. Raising the foot of the bed is helpful in some cases. Bleeding from the anterior urethra can be arrested by pressure. Bleeding from the bulbous or membranous urethra may be controlled by pressure applied to the perineum.

Finally, no patient ought to be allowed to die of haemorrhage without an attempt being made to restore him by transfusion of blood or intravenous injection of gum salic solution.

THE Union of International Associations of Brain Workers will hold a congress at Brussels from August 20th to August 22nd. The union was established in 1910. Before the war 230 associations of various kinds had joined it, of these 100 remained faithful, and took part in a congress held last year. Among the subjects to be discussed next August will be the steps which should be taken by brain workers to assert their rights in relation to both capital and labour, the difficulties encountered in the dissemination of periodical literature, and the steps which the League of Nations can take to carry out its avowed intention of helping brain workers. The subscription to the congress is 20 francs, and full particulars can be obtained on application to the Secrétaire du Congrès International du Travail Intellectuel, Palais Mondial, Parc du Cinquante-neuf, Bruxelles.

THE SCHICK REACTION:

A CLINICAL TEST FOR THE DETERMINATION OF
SUSCEPTIBILITY TO DIPHTHERIA.

BY

GLADYS WARD, M.D., D.P.H. EDIN.,

ASSISTANT MEDICAL AND CHILD WELFARE OFFICER, DEPTFORD.

*Preparation of the Toxin and Technique of the
Injection.*

For purposes of the Schick test¹ a toxin which has been ripened for at least a year, and then carefully standardized by determining the minimal lethal dose for a 250-gram guinea-pig, should be used. The bulk toxin will keep its strength very well if a ripened toxin is used. A dilution of the toxin is then made, of such strength that 1 c.cm. contains one-tenth of a minimal lethal dose. The amount actually injected in the test is 0.2 c.cm. of this dilution—that is, one-fiftieth of a minimal lethal dose.

To make the injection it is essential to have a short, sharp-pointed needle which fits accurately on the syringe. A 1 c.cm. record syringe is found most convenient. The flexor aspect of the right forearm just below the bend of the elbow is the selected spot. The arm having been first cleaned with ether or spirit, the skin is made taut between the forefinger and thumb of the left hand, and 1/5 c.cm. of the diluted toxin is injected intracutaneously. The result is absolutely useless if the injection be made subcutaneously. When done correctly a raised white wheal with a definite edge, and on which the pores of the skin are visible, is produced. Finally, if the test has been successfully performed, it should be possible to express a small drop of blood-stained serum from the site of the injection.

A true positive reaction is clearly visible at the end of twenty-four hours as a clearly circumscribed red area, generally about 1 inch in diameter, and accompanied by slight infiltration. This increases in intensity for the next three or four days, and then gradually fades, leaving a still distinct area of pigmentation and scaling. This pigmentation is generally faintly visible at the end of four or five weeks, and thereafter disappears. There is no general reaction. People who are using their arms a great deal may complain of some stiffness and local irritation.

A pseudo-reaction appears earlier, reaching its height in from twenty-four to thirty-six hours. It is not definitely circumscribed, and often shows a secondary areola, which fades off into the surrounding skin. The reaction begins to fade at the end of thirty-six hours, and has generally quite disappeared at the end of seventy-six hours, leaving no scaling; but, occasionally, a faint bluish mark persists on the skin for some days. The patient complains more frequently of stiffness and soreness of the arm, and in one or two cases a general reaction (headache, vomiting, etc.) has been noted.

A reaction is said to be *negative* when there is absolutely nothing to be seen at the site of the injection at any time.

The majority of the readings referred to in this paper were made at twenty-four hour, seventy-six hour, and seven-day intervals, the reasons for these intervals being as follows:

(a) At the end of twenty-four hours both the true and the pseudo-reaction, should it be present, are well marked.

(b) The pseudo-reaction has begun to fade at the end of forty-eight hours, and by the time seventy-six hours have elapsed has generally completely disappeared, thus rendering the second reading much simpler.

(c) The third reading was taken at the end of a week or ten days. I consider the latter quite reliable, and more convenient when dealing with patients in a general hospital.

The reading of the different reactions, after a short apprenticeship, presents little difficulty, except in cases complicated by a pseudo-element, and in these cases a "control" test may be done at a site on the left arm corresponding to the original test on the right. The control toxin is heated to 75° C. for ten minutes, whereby the specific toxin is destroyed, and the proteins, to which the pseudo-reaction is due, are left unchanged.

Careful records should be kept—these to include the name, age, and address of the patient, the date of injection, subsequent readings, and final remarks and results of each case.

It is, of course, essential that the toxin be reliable. I was fortunate in obtaining from Dr. Claude B. Ker one ampoule prepared by Dr. R. A. O'Brien, and which on passing to be entirely satisfactory. A small office of the urethra a local irritant action of minute as a ball valve, obstruct toxin given intracutaneously. A patient's symptoms. s that the individual is possessed of antibodies to neutralize the

toxin, and is therefore immune to the disease at the time when the test is made. According to Schick himself a negative reaction indicates at least 1/30th of a unit of antitoxin per cubic centimetre of blood—that is, sufficient to protect against diphtheria. Von Behring maintains that 1/100th unit is sufficient. A positive reaction indicates that the individual tested does not contain sufficient antitoxin in his blood to render him immune. A pseudo-reaction is probably a local sensitization phenomenon of a protean character, since a similar reaction can be produced with toxin heated to 75° C. for five minutes, or with dilutions of the autolyzed substance of the diphtheria bacillus in which no toxin is present.

Influence of Age on the Schick Reaction.

The following table has been compiled from tests done in the Royal Hospital for Sick Children and in Craighall Poorhouse Hospital, Edinburgh.

Age.	Number.	Negative.	Positive.	Percentage Positive.
0 to 6 months ...	25	23	2	8
6 months to 2 years ...	41	21	20	50
2 to 5 years ...	25	10	16	61
5 to 10 years ...	44	30	14	34
10 to 15 years ...	14	10	4	28
Total ...	150	94	56	37

Here we find that the greatest number of positive Schick reactions occurred in children between the ages of 6 months and 5 years. This we know to correspond with the age incidence of diphtheria.

The following is a table showing the number of deaths from diphtheria in this country in 1917.

All Ages.	- 1	1 -	5 -	10 -	15 -	25 -	35 -	45 -
648	42	404	145	33	6	7	3	8

From this we see that no less than 63 per cent. of the total number of deaths occurred between the ages of 1 and 5 years, and it is interesting to compare this figure with that quoted in the previous table of children between the ages of 2 and 5 years who give positive Schick reactions, the percentage of these being 61.

Influence of Concurrent Disease on the Reaction.

The following table gives the results in the scarlet fever wards:

Age.	Number.	Negative.	Positive.	Percentage Positive.
0 to 1 year ...	0	0	0	0
1 to 2 years ...	2	0	2	100
2 to 5 " ...	17	0	17	100
5 to 10 " ...	47	21	26	55.3
10 to 15 " ...	30	11	19	63
15 years and over ...	54	34	20	37
Total ...	150	66	84	56

These results, though comprising too small a number to be of great value, correspond fairly closely with those published by Dr. Leete² last year, his total percentage of positive results being 57.2.

Comparing the results between children tested in the scarlet fever wards and in the wards of a general hospital we find in the former 66 per cent. positive between the ages of 6 months and 15 years, in the latter only 37 per cent. For a long time, moreover, it has been a recognized fact that, in spite of all precautions, cases of diphtheria occur in the scarlet fever wards more readily than in others. Zingher³ suggests that there may be a destruction of the natural diphtheria antitoxin during an attack of

scarlet fever, while Von Behring has suggested that there is a temporary loss of natural immunity to diphtheria during the acute febrile stage of the disease.

Among the cases studied at the Sick Children's Hospital the actual disease from which the child was suffering at the time did not appear to have any definite bearing on the reaction, but the "acuteness" or "chronicity" of the case apparently bore a close relationship. The percentage of positive Schick reactions is given under the following headings:

Respiratory diseases (not tuberculous), 55.25 per cent. Alimentary diseases (not tuberculous), 50 per cent. Tuberculosis 45.5 per cent. Nervous disorders 33.5 per cent. Rheumatism 27 per cent. Rickets 16.6 per cent. Diseases of kidney and bladder 16.6 per cent. Congenital syphilis 14 per cent.

Another series of cases was then taken and divided into two groups—acute and chronic—care being taken to exclude entirely all such cases as could not be definitely classified.

The "chronic" cases included chronic tuberculous infections, long standing emphysema, congenital syphilis, etc., while the "acute" were chiefly made up of pneumonia, acute bronchitis, acute gastro-enteritis, etc. The results were as follows:

Of chronic cases 23 per cent. were positive.
Of acute cases 60 per cent. were positive

We see, therefore, that the number of positive Schick reactions found in the acute cases was as high as that found among scarlet fever patients. The figures obtained by Dr. Leete, in the 500 scarlet fever cases tested by him in the Edinburgh City Fever Hospital, show that between the ages of 1 and 15 years 60 per cent. were positive; my own figure is somewhat higher—namely, 67 per cent. "Acute general cases" in the same age group also gave 60 per cent. positive Schick reactions.

It was interesting to note, moreover, in several cases of *tabes mesenterica* tested, that most of those who came in almost in *extremis* and were "hopeless" from the first gave a strongly positive reaction, whilst those who were less severely infected and left hospital "improved" gave a negative reaction. Another interesting example was supplied by two sisters who were in the ward at the same time suffering from dysentery.

One was aged 7, the other 8, and neither of them had had diphtheria. The infection in both cases was by the *Shiga bacillus*. The younger, who was the more severely ill on admission and subsequently died, gave a strongly positive reaction, whilst the elder, who was only mildly infected and made a good recovery, gave a negative reaction.

It has been noted by various observers that immunity or non immunity to diphtheria runs in families. Is not this case, then, very suggestive of the fact that any acute infection may cause a temporary loss of natural immunity, and that the high percentage of diphtheria cases occurring in scarlet fever wards may also be explained on these grounds?

It has been suggested that the Schick reaction might be due to a general reaction on the child's part to any toxic material. Dr. Ellsworth Moody⁴ successfully established this as a fallacy by testing 180 children in the St. Louis Children's Hospital with intradermic tuberculin and diphtheria toxin, and by finding similar reactions in only 34 cases.

Influence of Pregnancy on the Reaction.

Report on a series of 50 maternity cases. With the exception of three or four all the tests were made during the first week of the puerperium, the babies' ages varying from two to eight days.

Mother and baby negative	45
Mother and baby positive	1
Mother negative, baby positive	1
Mother positive, baby negative	3

* Reaction doubtful (baby 4 months).

That is, 90 per cent of the mothers, and 95 per cent. of the babies, gave a negative reaction. Controls were done at the same time with toxin which had been heated to 75° C. for ten minutes. We found that no less than 30 (that is, 60 per cent) of the mothers, gave pseudo reactions, 27 of them occurring in the immune mothers and 3 in those who gave positive Schick reactions. Three of the 27 who showed a pseudo reaction had had diphtheria in infancy.

The actual technique in newly-born infants presented some difficulty, but only those results have been used in which a quite satisfactory injection (showing the well marked white wheal, etc.) was made. The natural

erythema of a young infant's arm rendered one or two readings doubtful at first, but complete absence of pigmentation or seching at the end of a week led one to the diagnosis of a negative reaction.

Finding 90 per cent. of negative reactions in puerperal women as compared with the 75 per cent. quoted by Schick in the records of the Willard Park Hospital, and the 67 per cent. found by myself in scarlet fever patients, raises once more the long vexed question of the possibility of pregnancy conferring temporary immunity to disease. It is, however, quite impossible, in a short paper such as this, to enter into the controversial literature on that subject.

The large number of pseudo reactions (90 per cent.) found among pregnant women, I think, endorses the view that the pseudo reaction is of the nature of a local anaphylaxis, the woman in this instance being sensitized by the protein absorbed through the placenta.

Immunity in the New born.

In the 50 odd cases tested only one baby gave a definitely positive reaction, and one in a 4 months baby was doubtful. Schick, however, found 7 per cent. of positive reactions in a series of nearly 300 tests made on new born infants. According to Zingher,⁵ the antitoxin of the infant obtained from the immune mother lasts for about six to nine months after birth. Kazzowitz and Groer⁶ found that 84 per cent. of mothers and their new-born infants contain a body which has the property of neutralizing diphtheria toxin, and this they identified with diphtheria antitoxin. This is present in mothers and infants, and, presumably, is transmitted through the placenta to the foetus, and because of its frequency is regarded as a physiological phenomenon. The fact that children of the same family give the same reaction also suggests an hereditary factor, which in the absence of infections by the *Klebs-Loeffler bacillus* gives rise to the presence of the so called natural antitoxin. That nearly all infants are born with a sufficiency of antitoxin to render them immune to diphtheria is an established fact; why it should persist in some children and disappear in others is still unexplained. Zingher tells us that only a few infants retain their maternal immunity after the twelfth month, and probably all lose it before the eighteenth month of life.

Our next consideration is that of the establishment of an artificial immunity, which will replace or supplement the natural, and carry the child safely through those years when he is most susceptible to the disease.

Active Immunization of Infants.

As the immunity conferred by the mother varies in the length of time it persists—disappearing in most cases at the end of six months, yet persisting in some children till the end of the second year of life—it is obvious that a negative Schick reaction is not reliable until after the second year. Park and Zingher⁷ adopted the following procedure in institutions:

Inmates six months or more in age were Schick tested. If positive they were immunized by intradermic injection of three doses of toxin antitoxin mixture.

Schick reaction were retested every third year because of the gradual loss of passive immunity in many. Those giving a positive test at any time were immunized. After the administration of the immunizing doses (work done by Dr. Blum) immunity developed in from three weeks to three months, and lasted more than two and a half years.

Speaking at the New York Academy of Medicine in 1918 Zingher said: "In children over 2 years of age a negative Schick test indicates a permanent immunity to diphtheria. Fully 99 per cent. of the children over 2 years of age who give a negative Schick reaction continue, when retested at a later period, to give a negative reaction."

He finds that those who gave a positive Schick reaction and were injected with toxin antitoxin were slow in producing antitoxin. Only 30 per cent. were found to be immune at the end of three weeks, but the Schick test in the other children became fainter and fainter and eventually became negative in most instances.

Later Schick tests showed that 95 per cent. of these children had become immune. He has also immunized children by three doses of toxin antitoxin and found that they gave negative Schick reactions when retested two and a half to three years later. He recommends that all positive reactors under 18 months be given three doses of toxin antitoxin, each of 0.5 c cm., one week apart; and that of the children over 18 months of age, and of adults, only those who give a positive reaction

should be immunized with toxin-antitoxin. They should have three doses of 1 c.cm. one week apart. Young children show no reaction.

In 1916 Park and Zingher² presented a paper based on a series of over 1,000 cases that had been actively immunized with diphtheria toxin-antitoxin. These susceptible individuals were selected by means of the Schick test out of a total of about 10,000 children and adults in ten different institutions. The mixtures of toxin-antitoxin that were used for immunization were either neutral (66 to 70 per cent. L.+ to each unit of antitoxin), or slightly toxic (80 to 90 per cent. L.+ to each dose of antitoxin) to the guinea-pig. The dose was varied from 0.5 c.cm. to 1 c.cm. and the number of injections from one to three. The injections were made subcutaneously at intervals of seven days.

The retests with the Schick reaction showed that only 30 to 40 per cent. became immune three weeks after the first injection, about 50 per cent. at the end of four weeks, 70 to 80 per cent. at the end of six weeks, and 90 to 95 per cent. at the end of eight to twelve weeks.

The best results were obtained with the full immunization consisting of three injections of 1 c.cm. each, given at weekly intervals. The duration of the active immunity was studied in a group of children that was followed up for over one and a half years; these cases showed that the active immunity persisted for at least that length of time. It is possible that the immunity induced by the injections of toxin-antitoxin started a combined cellular production of antitoxin, which would have otherwise appeared much later in life. The L.+ dose of toxin is the amount which, when mixed with 1 unit of antitoxin and injected into a 250-gram guinea-pig, will cause its death at the end of four days.

Conclusions.

1. The Schick test has given us very definite data as to which years are the most dangerous with regard to diphtheria infection in a child's life. These are between 6 months and 6 years, while the periods of lowest susceptibility appear to be under 6 months and over 15 years. These results are endorsed by clinical experience.

2. It is of great value in deciding the difficult question of whether a patient is a carrier or is really suffering from diphtheria. For example, a case of streptococcal tonsillitis in a diphtheria carrier would by culture alone be thought to be one of diphtheria. If a Schick test were done on such a case no doubt would be left—in the case of the test being negative it would be treated as a carrier, and if the reaction were positive, as a case of diphtheria. Similarly in a case with a nasal purulent or sanious discharge the same difficulty would arise and a Schick reaction here too would indicate the line of treatment to be followed.

3. It has, perhaps, its greatest value in showing us to whom, among persons exposed to infection (for example, contacts, doctors and nurses), we may safely omit to give antitoxin—thus greatly minimizing the risk of anaphylaxis and also saving pain and expense. When possible, only those nurses who give a negative Schick reaction should be employed in diphtheria wards.

4. We are able by means of the Schick test to ascertain, in cases which have previously had the disease or have had antitoxin, to what extent their immunity persists, and whether they have sufficient antibodies to overcome a fresh infection.

5. Lastly, it has supplied us with a basis on which to build new immunizing methods, which have given such encouraging results in America that we feel justified in looking forward with confidence to the day when diphtheria will be a disease well under our control, and the infant and child life of this country robbed of one of its chief horrors.

I wish to express my thanks to Dr. Claude B. Ker for his guidance in doing this work, and for permission to publish the results. I also wish to thank Dr. Stewart Fowler, Dr. Lamond Lackie, and Dr. H. Gibson for giving me opportunities of carrying out the tests in their respective wards.

A MONUMENT was recently erected in one of the public parks of Madrid to Dr. C. M. Cortezo, the Spanish physician and politician, who is editor of the *Siglo Médico*, in recognition of his long philanthropic and public activities. At the inauguration ceremonies, in response to many speeches, Dr. Cortezo said that he accepted the tribute only as homage to the medical profession.

THE TREATMENT OF SYPHILIS IN MACEDONIA ON ACTIVE SERVICE.

BY

TREVOR HAYMAN FOWLER, M.R.C.S., L.R.C.P. LOND.,
CAPTAIN (LATE R.A.M.C.).

LATE SPECIALIST IN VENEREAL DISEASE, BRITISH SALONICA FORCE.

THE experience of four and a half years in the army, the greater part of which time was spent in the diagnosis and treatment of venereal diseases, may justify a few remarks upon the methods employed in dealing with syphilis in Macedonia during the late war. I soon became impressed, first, with the importance of making a definite diagnosis as early as possible, and secondly, with the danger of the policy of applying local treatment to a venereal sore and awaiting results.

The hospital for venereal diseases contained some 300 beds, of which roughly a third were set apart for patients suffering from syphilis. Cases admitted to hospital with no other signs beyond a venereal sore were treated as follows: The sore was scraped and the exudate transferred to a microscope slide, a film made, stained by the Giemsa method, no other being at our disposal, and examined. If deemed advisable, the blood serum was tested by the Wassermann reaction, which was regarded as a help to diagnosis, but not relied upon alone, nor was it allowed to outweigh clinical evidence. Cases which left no room for doubt clinically were not necessarily subjected to the microscopic search for the *Spirochaeta pallida*, or to the Wassermann test. It is well perhaps to mention this fact, because in an article which appeared in the *Practitioner* for December, 1920, upon the Wassermann reaction, by Dr. C. Lundie, it was stated that in the army "a diagnosis of syphilis is not allowed, except when the *Spirochaeta pallida* is found or the Wassermann reaction is positive, and *per contra*, a cure is not admitted until both have become negative, a result in the case of the Wassermann sometimes impossible to attain."

The diagnosis having been made the patient was at once put under treatment, the usual course consisting of:

- (1) A weekly injection (intramuscular) of mercury.
- (2) Daily mercurial inunctions.
- (3) A weekly injection (intravenous) of "606" (salvarsan, kharsivan, diarsenol, galy), 0.3 gram, or a fortnightly injection 0.6 gram.
- (4) The urine was tested weekly, and treatment regulated thereby.
- (5) The patient was weighed at the commencement of treatment and at stated intervals throughout the course.

A rigid régime was insisted upon before and after the "606" injections; the reaction was usually slight, sometimes there was none. No cases of arsenical dermatitis occurred, and no suppurations ever followed the mercurial injections. Iodides were frequently given, but they did not form a part of the routine treatment. They were never used except in conjunction with mercury, not being regarded in themselves as a cure for syphilis.

Patients who had had repeated attacks of malaria, or who had suffered from dysentery or severe diarrhoea, and who had become debilitated thereby, did not make good subjects for this intensive treatment. As a rule mercury was withheld in these cases, at first altogether, and "606" administered in doses of 0.3 gram. If, as was usual, improvement took place, mercury was injected cautiously, a careful watch being kept for albuminuria or diarrhoea. A great many cases showed a mixed infection, due either to superimposed sepsis, or to the original sore containing pyogenic organisms. Suppurating inguinal glands were treated by simple surgical methods and were incised when "ripe"; at one time the plan of excising the glands before the skin had become involved was adopted; we found it tedious and without any appreciable advantages. The average stay of a patient in hospital was five to six weeks.

Each patient on leaving hospital was given a slip of paper which he was told to hand to his medical officer; whether this was always done is open to doubt. The advice given was to take one pill of hyd. c. cret. gr. ij each night for three months, to leave off for one month, and at the end of that month to have the blood tested by the

Wassermann reaction; he was told that if this was negative he should go on again exactly in the same way—that is, to take the pills for a further three months, to leave off for a month, and at the end of that month to have his blood tested again, and so on for at least twelve months. He was told that if the Wassermann reaction was at any time positive he should act according to further medical advice; the fact that the reaction was positive not being taken, in the absence of any signs of activity, as proof that a further course of intensive treatment was necessary or advisable.

Although we did not claim to "cure" after so short a course of treatment, we could claim that after a few weeks our patients were fit to carry on their duties in the trenches or elsewhere, which after all was an important matter in such a crisis.

RETROGRADE CATHETERIZATION FOR IMPERMEABLE STRICTURE OF THE URETHRA.

BY

W. J. FOSTER, F.R.C.S. (ENG.),

Surgeon, ROYAL BERKSHIRE HOSPITAL, READING.

THE operation here described is proposed as a substitute, in suitable cases, for Wheelhouse's operation, because it is easier to perform and gives better results from the patient's point of view.

Severe stricture of the urethra with retention of urine in the male is not as common in Reading as in London, but a few cases are admitted to the Royal Berkshire Hospital every year. Most of them can be treated by rapid dilatation under an anaesthetic, and quickly discharged from the wards to out-patients. Frequently before admission attempts have been made to pass a catheter, and the patient arrives with false passages and bleeding from the penis. In these cases I have the bladder aspirated above the pubes two or three times and try what rest, hot baths, and a free purge will do. Sometimes it is possible in a few days to pass a catheter and dilate the stricture. If this fails the patient is anaesthetized and a variety of catheters and sounds are tried. If I fail to get in even a filiform bougie the usual proceeding has been to do Wheelhouse's operation; but when there are false passages and a bleeding urethra this is often very difficult and tedious. Moreover, it leaves the patient with a urethra further damaged, the wound is in a bad place, and there is a chance of trouble with a urinary fistula and sometimes delay in healing. I have known several cases to do very well, and even with neglect after treatment on the patient's part to go very many years before they returned with acute retention of urine. Probably with reasonable care in passing a bougie the patient might have avoided further trouble. In many cases with false passages the difficulty of finding the tiny aperture of the stricture, together with the dirty position of the wound, and the sensitive area in which it is situated, condemns Wheelhouse's operation at the present day, although it was undoubtedly a good operation at the period when it was first performed. With modern experience in the treatment of suprapubic wounds, retrograde catheterization and dilatation of the stricture is preferable.

In such a case as I have described my method of late years has been, in the first place, to pass some sort of a catheter or bougie and perform rapid dilatation of the urethra. If this fails I select a time when the bladder is distended and make a suprapubic opening in the bladder; a No. 10 or 12 catheter (silver) is then taken in the right hand and easily passed into the bladder end of the urethra as far as the stricture. A No. 8 silver catheter is then passed into the penile urethra until it meets with the point of resistance of the stricture, avoiding the false passages if possible. The catheter in the bladder is then advanced with firm pressure, but without violence, until the stricture is stretched and pushed forwards as much as possible. With this catheter held firmly in position the No. 8 catheter is manipulated with the left hand and disentangled from any false passages; it is passed on carefully but firmly until metallic contact is made between the two catheters. Once certain of metallic contact some force and a little rubbing action may be used as long as the surgeon is certain the two catheters are touching at

their points. It is now easy to hold the points of the two catheters in contact, and to allow the penile catheter to push the bladder catheter gradually backwards until the former is in the bladder. A larger penile catheter is now passed in place of the No. 8. If the larger catheter gets trapped in the false passages it is very easy to slip in the bladder catheter again from the suprapubic wound and make contact with a penile catheter.

The urethra can now be rapidly dilated to No. 16 or 18, and a No. 12 silver or a large size hard rubber catheter tied in. The bladder is well washed out through the catheter and suprapubic wound and a drainage tube purso-stringed into the bladder wall. The wound is stitched up, or if too dirty the stitches are inserted and left untied for a few days. It is advisable to put a small drainage tube into the wound below the last stitch, if the wound is sutured at the time, in case of a leak by the side of the large tube. The suprapubic wound is treated as usual after a prostatectomy, and the catheter left in the urethra for a week. The bladder is washed out once or twice daily, according to the condition of the urine.

A case operated on recently by this method left the hospital in four weeks with the suprapubic wound healed, except a superficial granulation and a urethra that a No. 16 would drop through by its own weight. His recovery was delayed by a misunderstanding by which the catheter was removed in four days; the house-surgeon was unable to replace it. Under an anaesthetic a No. 18 sound passed quite easily, and I tied a fresh catheter in for a week. There was no further difficulty. If this had been done at first, as I directed, he would have been fit to go out some days or a week earlier.

I have been unable to find this operation described in any textbook on genito-urinary surgery. Thomson Walker mentions retrograde catheterization. He says: "Suprapubic cystotomy is performed, and retrograde catheterization with a metal sound. The point of this is cut down upon in the perineum. The operation has little to recommend it over the perineal dissection." This is only a method of doing Wheelhouse's operation. I have adopted it with advantage in a case in which I failed to find the aperture in the stricture after starting a Wheelhouse operation in the ordinary way. It certainly solved the difficulty. Should the operation I have described fail, it would be the quickest way of dealing with the difficulty. At present I have never found any necessity, as retrograde catheterization has invariably succeeded.

I think it is highly probable that other surgeons may be using this method of dealing with troublesome strictures, although I have failed to find any record. I am sure those who have not done so will find it a very easy and safe way of dealing with these cases, and the result very satisfactory to the patient. It is needless to say that the whole operation must be performed with strict surgical cleanliness.

In considering what damage is done to the urethra by retrograde catheterization, it is necessary to remember that the actual length of a stricture of the urethra may be considerable, perhaps from half an inch up to 1½ in. or more, but the part of the stricture that is really so small as to prevent the passage of urine or a fine bougie is short; in my opinion it rarely exceeds a quarter of an inch, and is often less. It is this portion that is nipped between the points of the two metal catheters. With a fixed point in the bladder end of the urethra, it is possible to force the penile catheter effectively through the constriction by steady pressure, or with a slight grinding movement. The exact size of the penile catheter may have to be varied, but the No. 6 to 8 is the usual size required to give the necessary rigidity. Once the catheters are in good metallic contact the whole difficulty is overcome.

The damage to the urethra is very slight, and the free drainage of the bladder tends to prevent any inflammatory reaction on the kidneys such as sometimes takes place after passing a catheter. The patient is far more comfortable afterwards, and is not so long in recovery on the average, in severe cases, as after Wheelhouse's operation. I can strongly recommend the operation in selected cases as easy, certain, and better for the patient.

A MONUMENT has been erected at Rome, Georgia, U.S.A., to the memory of Dr. Robert Battery, the originator of Battery's operation, oöphorectomy, first performed at Rome, U.S.A., in 1872. The chief address at the inauguration was made by Dr. Howard Kelly, of Baltimore.

SUGGESTED AUTOINOCULATION OF A
RODENT ULCER.

BY

S. C. DYKE, M.B., D.P.H.Oxon.,

PATHOLOGIST TO THE CLINICAL UNITS, ST. THOMAS'S HOSPITAL.

IN view of the interest attaching to the autoinoculation of malignant growths the following case may be worth recording:

F. L., a woman aged 71, was admitted to the wards of the Surgical Unit, St. Thomas's Hospital, under Sir Cuthbert Wallace, suffering from a large ulcer over the spine, in the sacro-iliac region. The ulcer, which on admission was about four inches in diameter, was preceded by a small itching papule about five years previously; it steadily increased in size and commenced to ulcerate about one year before the patient's admission to the hospital. As seen in the ward, the ulcer presented a hard, raised edge and was diagnosed clinically as an epithelioma.

The patient also showed a small ulcer on the left upper lip, clinically resembling a rodent ulcer. The history in regard to this was that the patient had been bitten at this spot by a dog about a year previous to admission. The wound healed to a certain extent, but then broke down, and had since remained as a small, slowly growing ulcer.

Both ulcers were excised by Mr. W. W. Wagstaffe, and on examination both proved to be rodent.

Up to a short time before admission the patient had been in the habit of herself dressing the ulcer on her back, and it is easy to understand how cells could have been carried from it on the patient's fingers to the fresh raw surface on her lip resulting from the bite. It is not suggested that there is any absolute proof that inoculation occurred in this way; cases of multiple rodent ulcer, where there is no question of autoinoculation, are common enough, and this may have been one of them. On the other hand, the coexistence of the original ulcerating growth and of a raw surface on an easily accessible place like the lip established a state of affairs very favourable to inoculation, and that such inoculation occurred may at least be regarded as highly probable.

The literature in regard to autoinoculation of malignant growths was very fully reviewed by Shattock and Dudgeon¹ in 1914. They record two cases, one reported by Batlin and one by Schimmelbusch, in which the evidence for autoinoculation by means of the fingers is so strong as to be almost conclusive. One of these cases was an epithelioma; the nature of the growth in Schimmelbusch's case is not mentioned. No instance of suggested autoinoculation of a rodent ulcer occurs among those collected in Shattock and Dudgeon's paper.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PERNICIOUS ANAEMIA: REPEATED DOSES
OF CALOMEL: RECOVERY.

THREE years ago I attended a married lady, 37 years old, for anaemia. There was no haemorrhage to cause it. The complexion was lemon-coloured. The number of red corpuscles was about three-fifths of the normal, the colour index was above normal (1.25), and there was poikilocytosis. She got steadily worse in spite of arsenic and other tonics, until she was confined to bed. As she complained of the irritation caused by passing uric acid crystals, of which there was a considerable amount, the arsenic was stopped, and she was given 2-grain doses of calomel at first twice a week for six weeks, afterwards once a week for another six weeks, and finally once a month; she has kept on with the monthly dose until the present time.

The improvement after a few doses of calomel was marked. The uric acid crystals disappeared, and the anaemia steadily improved.

With the exception of some red bone marrow tabloids, after she had begun to improve, and some soda mixture for dyspepsia, she had no other drugs. At the present time she feels and looks quite well. Blood smears sent to the Clinical Research Association were reported on as follows:

"A differential count of the white blood corpuscles gives the following result:

Polymorphonuclear neutrophils	...	32 per cent.
Small lymphocytes	...	62 "
Large lymphocytes	...	4 "
Eosinophiles	...	0.5 "
Mast cells	...	0.5 "
Myelocytes	...	1 "

"The red blood corpuscles seem to have a fairly high colour index. They vary considerably in size and very appreciably in shape.

"Megaloocytes are very common. Microcytes and poikilocytes are also seen.

"Diffuse basophilia is seen fairly frequently, and nucleated forms are present in the proportion of one megaloblast per 100 leucocytes.

"No normoblasts were seen. The films gave an impression of a fairly well-marked leucopenia. These films are very suggestive of pernicious anaemia."

South Norwood.

JOHN C. FERRIER, M.D.

TARTAR EMETIC FOR VENEREAL GRANULOMA.

IN the BRITISH MEDICAL JOURNAL of November 30th, 1920, Dr. H. Lovett Cumming of Shanghai strongly advocates the use of intramuscular injections of tartar emetic in early cases of venereal granuloma. Might I venture a plea in favour of the intravenous route, both on account of simplicity and of the excellent immediate results both in early and late cases?

All my cases have been native Papuans. During the past eight months I have treated 84 cases (40 males and 44 females); in every instance the patients left the hospital apparently cured after a course of intravenous injections of tartar emetic. It has been impossible to trace the after-history of the majority, so that no statement can be made as to how permanent these results may be. However, four cases seen six months after finishing the treatment showed no sign of relapse. On the other hand, three cases definitely relapsed within two months of finishing the injections; these three cases received a second series of six injections. One of these cases four months after the second series shows no signs of relapse, and the smooth, healthy condition of the scars would lead one to believe that the cure is permanent.

Method.

A solution of 1 per cent. tartar emetic in distilled or rain water is filtered and boiled for two minutes. The injection is given on the same day with a 20 c.cm. Record syringe; 10 c.cm., containing 0.1 gram, is given twice weekly for ten injections; an interval of ten days is allowed to elapse, and then five more injections are given. In the case of men the dose can be increased up to 15 c.cm., containing 0.15 gram, without any very troublesome reactions, but 0.2 gram seems to be a dangerous dose to give as a routine. Acute antimonial poisoning developed in one case after such a dose.

The injections were given generally into the veins of the arm. Any extensive leakage into the subcutaneous tissues resulted in a most painful swelling with much oedema, which subsided in about two weeks without suppuration.

The beneficial effects of this treatment are apparent after two injections—that is, at the end of the first week. The rate at which new epithelium covers the raw ulcerated surfaces is remarkable. Islets of epithelium dotted here and there over the denuded area spring into existence. In the extensive cases of long standing new epithelium grows out from the anal margin and urethral orifice.

W. E. GIBLIN, M.C., M.B.

Samarai, Papua (British New Guinea).

THE PRIMARY ORGANISM IN CYTRES.

The following may be of interest to some of your readers: A short time ago I was asked to investigate a small epidemic of cases showing the following symptoms: (1) Pains in the limbs, (2) headache, (3) pyrexia, (4) slight sore throat. Cases in all stages, from the acute to the convalescent, were examined.

Stained smears from cultures of nasopharyngeal swabs of the early acute cases showed a pure culture of a Gram-negative coccus. Cultures of the rest showed a variety of organisms, among which was the Gram-negative coccus. On taking smears from the pure cultures two days later, I found that the Gram-negative coccus was dead and staining very faintly, and that what before appeared pure cultures

now showed a variety of organisms resembling smears of the convalescent cases.

Apparently, what had happened in the convalescent cases had now happened *in vitro*—namely, the primary organism had died, and when this happened the other organisms which had been present in the mucus of the swab began to grow. So that—and this is the point I wish to make—unless cases had been examined in the very early stages, one would have made the mistake of ascribing the epidemic to mixed infection.

I may add that my experience has led me to believe that this difficulty of getting the primary organism is responsible for a number of the failures of vaccine therapy.

C. B. DYSON,

Captain R. A. M. C. Officer in Charge,
District Laboratory.

Shorncliffe

Reports of Societies.

ORGANISM CULTIVATED FROM CARCINOMATA.

At a meeting of the Edinburgh Obstetrical Society on June 8th, with Dr. Wm. Forster, President, in the chair, specimens of pathological and clinical interest were shown by the President, Drs. HAIG FERGUSON, H. S. DAVIDSON, G. R. LIVINGSTON, and ROBERTSON DODD.

Dr. JAMES YOUNG gave a preliminary communication on the life-cycle of an organism that he had obtained by cultivation from carcinomatous tumours. In culture the organism appeared ordinarily as oval or rounded bodies of different sizes and with a bipolar staining, and as bacillary forms of a length and thickness varying with the medium. The round forms were found to vary in size according to the stage in their development. All stages in their evolution were shown, and it was pointed out that in suitable media they proliferated actively. Under certain conditions they clumped together to form densely staining masses of a rounded or a lobulated character. Dr. Young said that he had succeeded in producing germination of these masses. In the process they at first became paler in areas, the remainder of the staining matter showing as masses of irregular size and shape. Eventually the whole spore mass became pale or finely granular, and minute rod-like structures were formed. These became free and developed into the bacillary forms, which Dr. Young believed were the vegetative phase of the organism. The filaments were long or short, and their thickness varied from very fine threads to comparatively thick elements. They usually stained deeply at each end, and they often had deeply staining granules along their course. Dr. Young believed that by cultivating pieces of carcinomatous tissue in a special medium, which he described, he had been able to recognize that the deeply staining masses, which are present commonly in the nucleus or in the intercellular spaces, are in reality spore masses. He had been able to watch them germinate into the rod-like or hyphal forms. He had isolated the organism from 28 cases of human carcinoma, and he had also obtained a similar organism from breast carcinoma in the mouse. As controls he had used the medium without tissue and with non carcinomatous normal or diseased tissue. He believed that the organism belonged to the fungi, but he had been unable so far to classify it. As far as he could say, he believed that the vegetative phase of the germ was passed in the nucleus.

THE fourth report of the Conjoint Board of Scientific Societies contains evidence that scientific investigation is being seriously hampered by the heavy cost of the publication of results. An exceptional number of papers are being communicated to the scientific societies, including many held up during the war, but the resources of the societies, which have not increased, are insufficient at present prices to publish even the normal pre-war numbers. The report contains an abstract of the third report of the Committee on the Water Power of the Empire, suggesting that a conference should be held with the various dominions and dependencies of the Empire with a view to the creation of an Imperial Water Power Board with powers to carry out a comprehensive policy for stimulating, co-ordinating, and where necessary assisting development throughout the Empire.

Rebichus.

THE DAWN IN EUROPE.

BETWEEN the history of ancient Greece and Rome and the close of the glacial period lies the long series of centuries which marks the dawn for modern humanity in Europe. These centuries, numbering roughly one hundred, and known to the archaeologist as the Neolithic and Bronze ages, have been calling for a historian these years past, one who could weave into a consecutive whole the dry facts unearthed by generations of grave-diggers. The best historian we have discovered, the man who has succeeded in painting a vivid and living picture from the scanty material now available, is JOHN M. TYLER, Professor Emeritus of Biology, Amherst College, U.S.A. In his volume, *The New Stone Age in Northern Europe*,¹ he seeks to answer questions we are all interested in: Whence came the fair-haired Nordic peoples who live round the North and Baltic seas? How did they come by their Germanic or Saxon speech? How did they come by their robust manner of living? To be sure the answers he gives us are not final—are not even satisfying—but the manner in which he propounds his problems and frames his answers are those of a facile artist.

He is one of those writers who can have justice done to them only by quotation. The first excerpt we cite is chosen from the chapter in which he pictures the kind of life led by the Indo-dwellers in central Europe some five or six thousand years ago:

"Could we have sat on one of these village platforms of a summer afternoon and looked out to the wheat fields on the shore, and seen the oxen come in with fish and fowl, and the cattle returning from the woodland pasture; could we have watched the men fashioning implements and all manner of woodwork, and the women grinding the grain or moulding the pottery, or spinning or weaving, we should have found a great deal to interest us. The fruit and berries, the smell of roasting fish and baking bread."

A clever picture which combines into a living whole the odds and ends gathered by generations of patient and learned archaeologists. Mr. Tyler's merits constitute even his defects, for to get his vivid results he has, time upon time, to convert probabilities into actualities.

Nevertheless, here is a writer who can waken the past and make it live with a verve. Another passage may be cited to show how he handles the "invention" of agriculture, the discovery which heralded the beginning of neolithic culture:

"When she turned homeward with her load of 'spoil, some berries, seeds, and small bulbs doubtless fell to the ground and escaped her notice. These grew and flourished in the richer soil around the hut or shelter, for all the garbage could not have accumulated in the hut. Some unusually observing woman noticed this and protected the plants, or even cultivated them a little with her digging stick . . . and gradually started a garden."

This passage is taken from p. 103, and when we come to p. 223 we find the author's gallant supposition has become a fact, for there we read:

"We have seen that women were the first great discoverers and inventors; discoverers and founders of all our household arts and crafts as well as of most of our science."

Our author has, as all good men should have, a "soft side" for women; but if we take as our guide to the past our experience of the present, then we fear it is difficult to allow the claims he here makes for the inventive faculty of early neolithic women.

In spite, however, of a too free use of his fancy and of his genius for painting homely pictures, he has written a book which is not only readable but deserves to be read, for it is founded on a very close and competent study of available literature. Indeed, the list of references to authorities given at the end of the book will prove useful to novice and expert alike. Above all, we wish he had broken away from the traditional story that the early history of man is that of a cradle-land in Asia from which wave upon wave of migrants have issued to give the world its present population. The true story will show many cradle-lands, and a world which was not always echoing the resounding tramp of migratory hordes.

A. KEITH.

¹ *The New Stone Age in Northern Europe* By John M. Tyler. London: Bell and Sons, Ltd. 1921. (Demy) 8vo, pp 323; illustrated. 15s. net.)

THE NURSING OF EYE CASES.

THE nursing of ophthalmic patients is a special branch of the nurse's duties; in ELLIOT's *The Care of Eye Cases*, she will find all that is necessary for her to know about the subject.² The book is divided into three parts: in the first are details on the anatomy of the eye, on asepsis and antisepsis in eye surgery, on drops and other remedial measures, bandages, shades and dressings, on the preparation for an eye operation and the care of the patient after operation. The second part deals with the more important diseases of the eye in a brief manner, but sufficiently for the purpose of the work; an appendix is devoted to instruments.

Every surgeon has his own ideas and his own technique, but we venture to think that few will cavil at the sound advice which is presented to the nurse on nearly every page of this book. Perhaps the author might with advantage have laid more stress on the necessity for a nurse who is looking after a case of blennorrhoea to wear a pair of protective goggles and rubber gloves for her own protection; and we should have welcomed a few paragraphs on the care of ophthalmic instruments. We note that the author considers that a Buller's shield is now little used; but we believe that many eye surgeons are old-fashioned enough to consider that a Buller's shield forms a most important part of the treatment of unilateral blennorrhoea and of diphtheria of the conjunctiva, both of them, it is true, conditions happily rare in this country.

The book is well brought out, the illustrations are numerous and very good, and the text remarkably free from typographical errors, though a few have crept into the appendix, such as Placido's disc, Liebrich's probes, the Moorfield's hook, while Streatfeild's name is misspelt. Junior ophthalmic surgeons, who have to deliver a short course of lectures to nurses on ophthalmic surgery, will find in this book an admirable foundation on which to build their lectures.

DISEASES OF CHILDREN.

The Diseases of Children,³ by the late Sir JAMES GOODHART, edited by Professor G. F. STILL, now appears in its eleventh edition, and so proclaims its still vigorous life. The book is well known, and its qualities are proved by the test of time. Its form and size remain the same, but the number of illustrations has increased to sixty. In its 900 pages it gives a sufficiently complete and an admirably practical account of the subject. Goodhart set out to write his book in 1885 from the standpoint of the clinician, and especially from that of his own clinical experience. Through successive editions, and since the accession of Dr. Still to joint authorship, these outstanding qualities have been retained. We find faithful and vivid clinical descriptions of disease and a constant appeal to clinical experience. It is not difficult to understand the success of a book conceived on this plan, and written by two men, each an acknowledged master of his subject in his own generation.

We have an impression that the student would find this an easier book to read if, in the accounts of the various diseases, a more prominent and systematic place were given to pathology, and if the accounts of symptoms in all their fullness and variety were more deliberately connected with the diseased processes underlying them. We would not have less said about symptoms; but it would assist the reader, especially the student reader, if pathology and morbid anatomy were given their paragraphs and subtitles as regularly as symptoms, diagnosis, and treatment. It is interesting to note Dr. Still's views on some matters of immediate interest and discussion. He is sympathetic but cautious towards the doctrine that rickets is due to the lack of a fat-soluble vitamin. He admits the therapeutic value of the newer arsenical preparations in the treatment of congenital syphilis, but on the whole prefers the older methods of treatment by mercury, which are simpler, less painful and dangerous, and probably, he thinks, as effective. He has not admitted the term *spasmodiphilia* into his account of tetany and laryngismus: the word is perhaps clumsy, but some term covering a variety

of clinical conditions that seem to belong to one group is useful. More might perhaps have been said about anaphylaxis, with reference to asthma and certain of the cases of urticaria and eczema in children.

We cordially welcome this new edition of a book that has now served the needs of students and practitioners of medicine for thirty-five years. Goodhart abhorred a compilation. He was not slow to acknowledge his debt to other writers and teachers, but in his book he aimed chiefly at communicating what he had learned and proved in his own wards and practice. Dr. Still carries on that good tradition, and so retains the great merit of the book, that it is written by those having authority, and not as the scribes.

THE CLACTON MILITARY HOSPITAL.

WHEN war broke out the Governors of the Middlesex Hospital offered their convalescent home at Clacton-on-Sea for the treatment of wounded and sick soldiers. The War Office accepted the offer, subject to the condition that a properly qualified medical officer could be found to reside in the hospital. The Board of Governors was faced with the difficulty that nearly all the hospital surgeons had been mobilized for various duties. There remained, however, the two gynaecologists, Dr. Comyns Berkeley and Dr. Victor Bonney, who, being over military age, accepted the post of resident medical officer to the hospital at Clacton between them. From August, 1914, to February, 1919, each of them took half-weekly turns of duty. Their work, surroundings, and experiences are recorded in *The Annals of the Middlesex Hospital at Clacton-on-Sea during the Great War*.⁴

The hospital was one of the "first-line" distributing hospitals in the Eastern Command, and during the four years and a half of its existence dealt with 9,242 patients suffering from all sorts of medical and surgical conditions, many of a serious nature. The solitary resident medical officer acted as physician, surgeon, specialist, x-ray expert, house-surgeon, house-physician, and registrar—just as if these two gynaecologists were officers in the R.A.M.C., ready to go anywhere and do anything, though neither, in fact, held a commission. The volume is not a record of scientific work; the description of the medical and surgical results is condensed into 14 of the 127 pages. The book is a chatty account of life in a soldier's hospital during the war at an exposed position on the East Coast. It is filled with many anecdotes of the medical officers, the matron, sisters and V.A.D.'s and other members of the staff, and of the patients; the hospital dog, donkey, and motor car are not forgotten. The illustrations are many, and consist of sketches, often comic in nature, by James Gibbon, Dr. T. Grimsdale, and Dr. Eric Fagan, and of photographs, some of which are somewhat spoiled by a curious speckling. At the end of the book is a complete list of the staff, the auxiliary hospitals to which patients were distributed, and the regiments to which patients belonged. There is also a list showing the extent to which the shower of honours connected with the war reached the Clacton Hospital; a list chiefly remarkable for its brevity. The Royal Red Cross reached the matron, the housekeeper, and a nurse. The strenuous labours, and sacrifice of time and money by the honorary surgeons appear to have passed quite unnoticed; there is no mention even of letters of thanks. No doubt the explanation is that Clacton, as one of the authors describes it, is really "off the map." It leads nowhere, and the only way out is the way you came in. The object in publishing the book is to advance the cause of the Middlesex Hospital by drawing attention to one part of its war services. There must be many to whom the story will appeal, and we wish the authors every success in their enterprise.

NOTES ON BOOKS.

THE second quarterly instalment of vol. Ixxi of the *Guy's Hospital Reports* reflects credit on the energy of the editor, Dr. A. F. HURST, both for its punctuality and for the interest of its contents, which have not, as some-

³ *The Diseases of Children*. By the late Sir James Frederick Goodhart, Bt., M.D., LL.D., Aberd., F.R.C.P. Edited by G. F. Still, M.A., M.D., F.R.C.P. Eleventh edition. London: J. and A. Churchill, 1921. (Demy 8vo, pp. 957; 60 figures. 32s. net.)

⁴ *The Annals of the Middlesex Hospital at Clacton-on-Sea during the Great War, 1914-1919*. London: W. J. Clark and Co. 1921. (Fcap 4to, pp. 127. Illustrated.)

⁵ *Guy's Hospital Reports*, vol. Ixxi (vol. i, Fourth Series, No. 2, April, 1921; pp. 137-251. Edited by A. F. Hurst, M.D. London: Henry Frowde, and Hodder and Stoughton, 1921. (7s. 6d. Subscription for volume of four numbers, £2 2s.)

times happens in hospital reports, been previously published. The first article is by Dr. Newton Pitt. In *Memorandum* of the late Dr. P. H. Pye Smith, who died in 1914; it quotes some of his numerous aphorisms, the last to the effect "Be sympathetic, and never give a minute diagnosis to the patient himself." Sir William Hale White supplements his recent article on "Richard Bright and the discovery of the disease bearing his name" by another on his observations other than those on renal disease. The fourth of Dr. J. A. Riley's studies in gastric secretion records experiments performed on himself to ascertain (1) the degree of discomfort entailed by swallowing and retaining the gastric tube, and (2) the satisfactory response to a standard test meal in a healthy subject; on no occasion was any real difficulty experienced in swallowing the tube, and after the first trial no unpleasant symptoms of any kind was noted, talking and even mastication not being interfered with. Hom glass contraction of the stomach is admirably described and illustrated in an article by the Editor and Mr. R. P. Rowlands. Mr. A. W. Ormond discusses the pathological effects of the visible and invisible spectrum on the eye, and points out the need for further information on the exact wave lengths responsible for the morbid effects. Two cases of unilateral hysterical deafness cured by the monochord, an instrument consisting of a steel bar designed to produce high notes, are recorded by Mr. Mollison, and as Mr. T. B. Lawton advocates local anaesthesia for the removal of tonsils in adults, and Mr. Zamora reports four cases of mastoiditis and complications without pyrexia or orrhea, the throat and ear department is well represented. Dr. G. W. Nicholson's studies on tumour formation show a philosophic outlook and much thought, and the volume closes with a case of impacted upper wisdom tooth removed by Mr. Rowlands and Mr. M. I. Hopson.

The fourth edition of the *Elements of Practical Medicine* by the late Dr. A. H. CARTER, who died in 1918, appeared in 1912, and last year the eleventh was revised and brought out by Dr. A. G. GIBSON, Lecturer on Morbid Anatomy in the University of Oxford, and Physician to the Radcliffe Infirmary and County Hospital, Oxford. A happier choice of an editor it would have been difficult to find, for Dr. Gibson keeps an accurate watch on the pulse of current medical opinion and has performed his duties with a due sense of proportion. The war has considerably modified aided to our knowledge of some diseases, and care has been taken to incorporate as much of this as comes within the scope of this well known manual, which, by its title implies, is strictly elementary and more suited for the student when commencing clinical work than for the practitioner. In a short appreciation Dr. Carter is described as representing that type of English doctor of which Sydenham was the earliest example.

Prof. O'DONOGHUE's *Introduction to Zoology* for medical students supplies a definite want. The types selected are those which usually appear in the syllabus of elementary examinations in zoology, though the arrangement is somewhat different. The author has adopted Huxley's method of commencing with a vertebrate type, in this case the frog. He deals next with the protozoa, including the life history of the malarial parasite, coelenterates, earthworm, dogfish, and rabbit. A chapter is devoted to histology and cytology, another to evolution, variation, and heredity, and two to embryology, the chick and the rabbit being selected as the examples in dealing with organogeny and later development. The book is clearly written and understandable. The illustrations are not too loaded with detail, so that they can be followed easily by the beginner. Physiology is dealt with more fully than is usual in a textbook of zoology, and there is a short account of such matters as toxins and antibodies generally. These are valuable additions for all students, more particularly students of medicine, for whom the book is primarily intended. It is a most useful textbook for the elementary student, and any one who has mastered it has a good solid foundation on which to build.

Most medical men who were on active service during the war have an idea that if they cannot speak French fluently at least they can understand the language. When, however, the average man attempts to read a French medical work—and those who looked a few years ago to

Germany as the fount and origin of modern medical matters may well be surprised at the wealth of scientific information that French medicine has to offer—he is humbled by his ignorance of the precise meaning of many of the scientific terms. To his aid comes the *French-English Medical Dictionary* that Dr. ALFRED GORRIS of Philadelphia, has edited. It is full, and appears, so far as we have tested it, to be accurate. It can be commended as a very useful little volume.

The *Large Municipal Directory and Year Book*, which has now attained its thirty-ninth annual issue, is a useful directory of the British and Colonial municipal corporations and county, urban, and rural councils. It includes lists of the chief officials, with their addresses and telephone numbers. There are also special articles on such subjects as public health, public cleansing and waste utilization, housing and town planning, practical sanitation, and sewage disposal, containing reviews of recent progress on these problems and descriptions of all the approved methods. The volume may be commended to the attention particularly of public health officials.

APPLIANCES AND PREPARATIONS.

A Compact Warm Ether Inhaler

Dr. G. A. THOMAS (Assistant Physician, Laidlaw & Hopital, Hastings), writes: "The advantages of warm ether vapour for anaesthesia by the open method are generally admitted; they were described by Simpson in this country in 1816, and considerable experience was afforded later by the use of his apparatus at many of our clearing stations and hospitals during the war. I have, however, felt the need of an inhaler of some kind which being independent of an extraneous source of heat, and needing no continuous air pumping, would be sufficiently compact to be easily accommodated in the smallest of cases, and I could use warm ether vapour to a sufficient extent. A fairly obvious device is the utilization of a heat chamber so lost to the patient in his expired breath, this takes place in all closed forms of inhaler, and to a certain degree with open methods is unnecessary. It is incidentally exactly comparable to the exhaust heating of a motor car carburettor. The inhaler in which I have employed this device somewhat resembles the small 10 lb. Dwyer instrument, and consists (see illustration) of three parts: (1) a face piece carrying the usual rubber cushion and providing the inspiratory and expiratory valves; (2) a radiating chamber containing nineteen thin metal tubes, and (3) a container for sponge or gauze upon which the ether is dropped. The ether is inspired from the container through the warmed 'radiator' tubes, while the expired breath is directed by the expiratory valve through a short passage into the radiating chamber, where it passes between the tubes, to which it gives some of its heat, and escapes through holes in the opposite side. The radiator is locked to the face piece by a small screw, and the container can be revolved into any convenient position for the dropping of ether. The inhaler is strictly of the semi-open type, but the arrangement has been kept everywhere as free as possible to prevent restriction of breathing and promote interchange of heat, a slight amount of rebreathing is allowed by the volume of the face piece, the in and out going streams being otherwise separate. Without the radiating chamber in use the temperature of the inspired vapour above the face piece is from 32 to 33 F. This is considerably lower than is shown by a thermometer under a Skinner's mask during 'open' administration, but here the actual temperature is variable and uncertain owing to the fluctuation of the alternate warm and cold streams. On bringing the radiating chamber into use the temperature rises in the course of a few minutes to 65–70 F., occasionally higher, generally rather above room temperature, and remains fairly steady. This is again not so high as can be obtained with an extraneous source of heat, but is, I think, sufficient for the purpose. There is a considerable economy of ether over the use of a mask, and a welcome diminution in the amount of ether in the air surrounding operator and anaesthetist. Anaesthetic mixtures can be used equally well if desired. The instrument is made entirely of metal except for the rubber cushion and the valve flaps; it can therefore be readily sterilized. Its length is approximately 7 in. and its weight 13 oz. It has been made for me by Messrs. Down Brothers, St. Thomas's Street, S.E. 1. I have not been able to find any description of an inhaler on these lines; if such exists I must apologize to the designer for my unconscious plagiarism."

Elements of Practical Medicine. By Alfred H. Carter, M.D., M.Sc. F.R.C.P. Revised by Alexander G. Gibson, M.A., M.D., F.R.C.P. Eleventh edition. London: H. K. Lewis and Co., Ltd. 1920. (Ct. 8vo. pp. 634 + 2, 15s. net.)
An Introduction to Zoology. For Medical Students. By C. H. O'Donoghue, D.Sc. F.Z.S., Professor of Zoology, University of Manitoba. London: G. Bell and Sons, Ltd. 1921. (Demy. 8vo., pp. 511, 17s. 6d. net.)

X-RAY AND RADIUM PROTECTION.

PRELIMINARY REPORT OF COMMITTEE.

THE X-Ray and Radium Protection Committee, representing the various radiological and other scientific bodies with their headquarters in the metropolis, after deliberating for some weeks, has issued its preliminary report, which is admittedly tentative in some of its recommendations. This report, which is a carefully thought out statement of present knowledge in regard to equipment, ventilation, and working conditions of x -ray and radium departments, as a matter of considerable urgency owing to the constant demand for guidance from individuals and institutions; it is printed in full below. After the completion of this, the preliminary part of its work, the Committee intends to proceed with its more extensive objects which may entail considerable research.

The chairman of the Committee is Sir Humphry Rolleston, K.C.B. The other members are: Sir Archibald Reid, K.B.E., C.M.G. (St. Thomas's Hospital), Dr. Robert Knox (King's College Hospital), Dr. G. Harrison Orton (St. Mary's Hospital), Dr. S. Gilbert Scott (London Hospital), Dr. J. C. Mottram (Pathologist, Radium Institute), Dr. G. W. C. Kaye, O.B.E. (National Physical Laboratory), and Mr. Cuthbert Andrews. The honorary secretaries are Dr. Stanley Melville (St. George's Hospital) and Professor S. Russ (the Middlesex Hospital).

Suggestions and offers of personal or other assistance are invited, and should be sent to the Honorary Secretaries of the Committee, care of Royal Society of Medicine, 1, Wimpole Street, W.1. Copies of the preliminary report may be had on application to the Honorary Secretaries.

Introduction.

The danger of over-exposure to x rays and radium can be avoided by the provision of efficient protection and suitable working conditions. The known effects on the operator to be guarded against are: (1) Visible injuries to the superficial tissues which may result in permanent damage. (2) Derangements of internal organs and changes in the blood. These are especially important, as their early manifestation is often unrecognized.

General Recommendations.

It is the duty of those in charge of x -ray and radium departments to ensure efficient protection and suitable working conditions for the personnel.

The following precautions are recommended:

1. Not more than seven working hours a day.
2. Sundays and two half-days off duty each week, to be spent as much as possible out of doors.
3. An annual holiday of one month, or two separate fortnights.

Sisters and nurses, employed as whole-time workers in x -ray and radium departments, should not be called upon for any other hospital service.

Protective Measures.

It cannot be insisted upon too strongly that a primary precaution in all x -ray work is to surround the x -ray bulb itself as completely as possible with adequate protective material, except for an aperture as small as possible for the work in hand.

The protective measures recommended are dealt with under the following sections:

- I. X rays for diagnostic purposes.
- II. X rays for superficial therapy.
- III. X rays for deep therapy.
- IV. X rays for industrial and research purposes.
- V. Electrical precautions in x -ray departments.
- VI. Ventilation of x -ray departments.
- VII. Radium therapy.

It must be clearly understood that the protective measures recommended for these various purposes are not necessarily interchangeable; for instance, to use for deep therapy the measures intended for superficial therapy would probably subject the worker to serious injury.

I.—X RAYS FOR DIAGNOSTIC PURPOSES.

(1) *Screen Examinations.*

(a) The x -ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 2 mm. of lead. The material of the diaphragm to be equivalent to not less than 2 mm. of lead.

(b) The fluorescent screen to be fitted with lead-glass equivalent to not less than 1 mm. of lead, and to be large enough to cover the area irradiated when the diaphragm is opened to its widest. (Practical difficulties militate at present against the recommendation of a greater degree of protection.)

(c) A travelling protective screen, of material equivalent to not less than 2 mm. of lead, should be employed between the operator and the x -ray box.

(d) Protective gloves to be of lead-rubber (or the like) equivalent to not less than $\frac{1}{2}$ mm. of lead and to be lined with leather or other suitable material. (As practical difficulties militate at present against the recommendation of a greater degree of protection, all manipulations during screen examination should be reduced to a minimum.)

(e) A minimum output of radiation should be used with the bulb as far from the screen as is consistent with the efficiency of the work in hand. Screen work to be as expeditious as possible.

(2) *Radiographic Examinations ("Overhead" Equipment).*

(a) The x -ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 2 mm. of lead.

(b) The operator to stand behind a protective screen of material equivalent to not less than 2 mm. of lead.

II.—X RAYS FOR SUPERFICIAL THERAPY.

It is difficult to define the line of demarcation between superficial and deep therapy. For this reason it is recommended that, in the reorganization of existing, or the equipment of new, x -ray departments small cubicles should not be adopted, but that the precautionary measures suggested for deep therapy should be followed. The definition of superficial therapy is considered to cover sets of apparatus giving a maximum of 100,000 volts (15 cm. spark-gap between points; 5 cm. spark-gap between spheres of diameter 5 cm.).

Cubicle System.

Where the cubicle system is already in existence it is recommended that:

1. The cubicle should be well lighted and ventilated, preferably provided with an exhaust electric fan in an outside wall or ventilation shaft. The controls of the x -ray apparatus to be outside the cubicle.

2. The walls of the cubicle to be of material equivalent to not less than 2 mm. of lead. Windows to be of lead-glass of equivalent thickness.

3. The x -ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 2 mm. of lead.

III.—X RAYS FOR DEEP THERAPY.

This section refers to sets of apparatus giving voltages above 100,000.

1. Small cubicles are not recommended.

2. A large, lofty, well ventilated and lighted room to be provided.

3. The x -ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 3 mm. of lead.

4. A separate enclosure to be provided for the operator, situated as far as possible from the x -ray bulb. All controls to be within this enclosure, the walls and windows of which to be of material equivalent to not less than 3 mm. of lead.

IV.—X RAYS FOR INDUSTRIAL AND RESEARCH PURPOSES.

The preceding recommendations for voltages above and below 100,000 will probably apply to the majority of conditions under which x rays are used for industrial and research purposes.

V.—ELECTRICAL PRECAUTIONS IN X-RAY DEPARTMENTS.

The following recommendations are made:

1. Wooden, cork, or rubber floors should be provided; existing concrete floors should be covered with one of the above materials.

2. Stout metal tubes or rods should, wherever possible, be used instead of wires for conductors. Thickly insulated wire is preferable to bare wire. Slack or looped wires are to be avoided.

3 All metal parts of the apparatus and room to be efficiently earthed.

4 All main and supply switches should be very distinctly indicated. Wherever possible double pole switches should be used in preference to single pole. Fuses no heavier than necessary for the purpose in hand should be used. Unemployed leads to the high tension generator should not be permitted.

VI.—VENTILATION OF X-RAY DEPARTMENTS.

1. It is strongly recommended that the x-ray department should not be below the ground level.

2 The importance of adequate ventilation in both operating and dark rooms is supreme. Artificial ventilation is recommended in most cases. With very high potentials coronal discharges are difficult to avoid, and these produce ozone and nitrous fumes, both of which are prejudicial to the operator. Dark rooms should be capable of being readily opened up to sunshine and fresh air when not in use. The walls and ceilings of dark rooms are best painted some more cheerful hue than black.

VII.—RADIUM TREATMENT.

The following protective measures are recommended for the handling of quantities of radium up to one gram.

1 In order to avoid injury to the fingers the radium, whether in the form of applicators of radium salt or of emanation tubes, should always be manipulated with forceps or similar instrument, and it should be carried from place to place in long handled boxes lined on all sides with 1 cm. of lead.

2 In order to avoid the penetrating rays of radium all manipulations should be carried out as rapidly as possible, and the operator should not remain in the vicinity of radium for longer than is necessary. The radium, when not in use, should be stored in an enclosure, the wall thickness of which should be equivalent to not less than 8 cm. of lead.

3. In the handling of emanation all manipulations should, as far as possible, be carried out during its relatively inactive state. In manipulations where emanation is likely to come into direct contact with the fingers thin rubber gloves should be worn. The escape of emanation should be very carefully guarded against, and the room in which it is prepared should be provided with an exhaust electric fan.

Existing Facilities for Ensuring Safety of Operator

The governing bodies of many institutions where radiological work is carried on may wish to have further guarantees of the general safety of the conditions under which their personnel work.

1 Although the Committee believe that an adequate degree of safety would result if the recommendations now put forward were acted upon, they would point out that this is entirely dependent upon the loyal co-operation of the personnel in following the precautionary measures outlined for their benefit.

2 The Committee would also point out that the National Physical Laboratory, Teddington, is prepared to carry out exact measurements upon x-ray protective materials and to arrange for periodic inspection of existing installations on the lines of the present recommendations.

3. Further, in view of the varying susceptibilities of workers to radiation, the Committee recommend that wherever possible, periodic tests—for example, every three months—be made upon the blood of the personnel, so that any changes which occur may be recognized at an early stage. In the present state of our knowledge it is difficult to decide when small variations from the normal blood count become significant.

NURSING associations in the United States of America have collected a sum of money to erect a memorial to the 284 American nurses who gave their lives in the war. It takes the form of a new building for the Florence Nightingale Training School for Nurses at Bordeaux, founded twenty years ago by Dr. Anna Hamilton.

The third international post graduate course in balneology and balneotherapy will be held at Carlsbad from September 11th to September 17th, when lectures will be delivered by members of the medical faculties of Berlin, Breslau, Budapest, Erlangen, Göttingen, Halle, Prague, Rome, San Pablo (Biarritz), Stockholm, and Vienna. The opening address will be given by Dr. Abderhalden of Halle.

THE PRIVATE CLINIC SYSTEM.

DISCUSSION AT THE ROYAL SOCIETY OF MEDICINE.

A GENERAL meeting of the Fellows of the Royal Society of Medicine was held on June 16th, under the presidency of Sir JOHN BLIND SUTTON, to discuss the question of the private clinic system in Great Britain.

Sir THOMAS HORDER, who used the American term "group medicine," said that there was nothing new in this conception. The principle was in daily operation in most of the general hospitals, where patients were often transferred from one ward or department to another so as to secure for them the benefits of the service most nearly adapted to the nature of their disease. The facilities for group practice afforded by general hospital conditions had led to increased efficiency so far as the patient was concerned, and had also contributed to the advance of medical knowledge. It seemed natural, therefore, to consider some adaptation of the method to private practice; perhaps such a development was already overdue, and if the profession did not itself arrange for group medicine its hand might be forced by the public, and that would bring about many professional complications. The problem of the nursing home was bound up with this question of group diagnosis and treatment. The patient of moderate means wondered why little or nothing had been done to improve the present condition in this respect and if the development of group clinics hastened the arrival of institutions properly equipped and administered to replace the small private houses, used as nursing homes, group medicine would at least have done something which would go far in its justification. Any clinic system must be planned so as to supplement the ordinary routine examination of the patient by the clinician for expert investigation, and must also offer his facilities for more thorough and therefore more beneficial treatment than could be undertaken by any individual practitioner. It should also save time both for doctor and patient without sacrifice of efficiency. A practitioner working with a number of persons, who were in effect his assistants, and had no special knowledge or training, was a group indeed but one which did not fulfil the requirements, and the same was true of a group consisting of a number of practitioners or consultants working together but not chosen so as to represent the various branches of medicine. A true group which did fulfil the requirements had down consisted of a number of practitioners or consultants of equal professional status, chosen carefully—"hand picked," as the Americans said—so as to be representative of various branches of medicine. Another system which fulfilled the requirements, although it was not a true group, was one in which a practitioner of great experience and balanced judgment first himself made a careful routine examination of the patients, and then referred them to particular specialists who were in association with him for expert investigation and report. The first of these units he called a group clinic, and the second a personal clinic. The group clinic had certain advantages. It could deal with patients having a large variety of diseases, and it would naturally have some arrangement by which its constituent members would be readily available for the expert examination of any patient. The chief of the personal clinic, on the other hand, must make his own special arrangements with his experts. In the group clinic meetings of all the members could take place at a settled time, whereas the chief of the personal clinic would rarely if ever meet all his experts together. Nevertheless, the personal clinic had advantages of its own. Its chief was brought into close touch with each patient, whereas in a group this personal relationship would tend to lapse, at least in respect to those patients whose trouble was found to concern more than one member of the group. The success of any form of group medicine depended upon a sound judgement at the outset in deciding what expert examinations were necessary, upon the subsequent co-ordination or integration of the various expert reports, and upon the decision as to a programme of treatment, and Sir Thomas Horder rather thought that in these respects the personal clinic would score. To send a patient round to a number of experts quite apart from the whole position of group medicine, and regard to finance also, much more was to be gained by the group clinic than the personal clinic. It was difficult to see how, under the group system, a first rate fee could

be arrived at without considering the members of the group as partners in a concern. On the other hand, the specialists attached to a personal clinic might be paid their customary consultation fees as extras. As a general financial principle, he thought it would be better to charge a smaller rate for the original survey, and then a surcharge for whatever special services were necessary, rather than to institute a larger flat-rate fee to cover all services. He left the problem of distribution among the members of the group to other speakers, and also the question of legal relationship, whether a deed of partnership or the setting up of an incorporated body was preferable. Certain precautions must be taken to prevent the growth of undesirable cliques, which would impair the cordial relationships existing at present among members of the profession. He feared also that the personal relationship between doctor and patient would tend to lapse in group medicine; it might be maintained by making the group no larger than was absolutely necessary to cover the main branches of practice, and by each member guarding the personal relationship of all patients who came originally to him. Up to now the private clinic supervised by one man who was fitted for this kind of work had been more easy to set going than the group clinic, yet it seemed highly probable that the group clinic would become a British institution. He believed that it had a better future than the personal clinic, although, of course, initial experiments must be regarded critically and its limitations must be faced—as, for instance, that it was less fitted for rural than for urban areas, and that some men were temperamentally less able than others to work in a team.

Sir HUMPHRY ROLLESTON said that the expression "team work" first became familiar in connexion with research into problems necessitating collaboration between experts in various branches of medicine. There its advantages were obvious, and its application to practice followed naturally. The question was how to place within the reach of the rest of the population the advantages which the necessitous poor got in the ordinary hospitals. To a certain extent practitioners in partnership had endeavoured to carry out the team idea. In choosing a junior partner, for instance, they would apply to the schools for one familiar with recent advances in surgery, and the older partners would give up their holiday for post-graduate instruction along some special line, so as to be authorities on a particular subject in their locality. He went on to refer to the great development of the Mayo Clinic at Rochester, Minnesota, and said that those who had had the opportunity of seeing the phenomenal success which had followed the organization of the Mayo brothers felt like the Queen of Sheba after her visit to Solomon. The Mayo Clinic had now become an educational and research institution as well, but originally it was an excellent example of a surgical clinic—the cases were mainly surgical—run on these group lines of medicine. There was room for a great deal of variation in the personnel and arrangements of team work; the team and its equipment might be made comprehensive, or it might be confined to a surgical or specialist function. The patients might be merely those belonging to members of the particular group, who had united their former practices so as to economize time and secure more satisfactory results, or they might be patients sent by outside practitioners for the purpose of diagnosis, to be returned with the report. In large cities there would be room for both these arrangements. In a small town the team might act injuriously to the interests of practitioners who were not members, and this must be prevented as far as possible. But in any case a team in an organized form was bound to come, if it had not already arrived. From the patient's point of view there was no doubt that a systematic examination by all available methods of the laboratory would be a great advantage. The procedure would be economical because the equipment would be concentrated in one establishment, so that the inclusive charge to the patient might be lower than would be the aggregate of fees under ordinary circumstances, while yet the return to the members might be higher. Medical men, with this combination of facilities and accessibility of advice, would get through their work in a more satisfactory manner and with less waste of time. A team of consultants and experts would be in the same position as a firm of general practitioners; as members of a team they might be regarded as a company, but he saw

no difficulty in securing any necessary statutory amendments to meet the position.

Dr. DRURY PENNINGTON spoke as a general practitioner who had had country experience. His attempts to get team work started had met with individual encouragement, but collectively there was a certain shyness among medical bodies, which hesitated to pronounce one way or the other. The most articulate objection was that the time was not ripe; but certainly the time was judged to be ripe for combination in all lines of trade and commerce. Was the medical profession alone to continue in the old-fashioned way? He maintained that the time was ripe, and for two reasons: (1) the rapidly decreasing power of the public to pay the old dues; (2) the formidable increase in the cost of diagnosis alone during the last fifteen years. When confronted with a chronic case having a multiplicity of symptoms probably arising from some fundamental cause or causes, he had found it necessary, in order to assure himself of the accuracy of his diagnosis, to apply to the bacteriologist and other experts for some of the links in the chain of evidence, but he had always to consider the patient's pocket, and this difficulty was often only surmounted by begging for gratuitous service from his colleagues—to which he greatly objected—or by converting his own fee into payment for such service. No one more highly appreciated the value of the advice of specialists than he did, but he thought that specialism sooner or later tended to produce a mental myopia, and the whole was sometimes lost in the part. He found himself often forced into being an arbiter between the conflicting opinions of rival specialists. He conceived it his duty to keep his eye on the individuality of his patient. He found himself less and less consulting with the man whose sole armamentarium was a stethoscope. Before many years were out he believed the general consulting physician would cease to exist, but he would find his regeneration in the rôle of assessor to a team. Dr. Pennington held that the time was ripe for an adaptation of medical practice to the evident requirements of modern science and economics alike. The formation of teams all over the country, each suited to the local requirements, must supersede the present system of individualism, and the faults which existed here and there in private practice would tend to disappear when the individual himself was no longer the only one to be considered.

Mr. BISHOP HARMAN said that he felt honoured in being asked to contribute to the discussion as Chairman of the Hospitals Committee of the British Medical Association, but he wished to make it clear that he had no authoritative information to give. There were certain points, however, which might throw light on professional feeling in the matter of these private clinics. During the war the Central Medical War Committee urged private practitioners to combine in order to foster subdivision of their work, thereby promoting economy and higher attainment in special branches, and to facilitate continuity during illness, holidays, and periods of study. The recommendation was well received and was acted upon with success. A combination for in-patient work in a private hospital in the provinces had been under review, and no exception had been taken to it. In general, he thought, the principle of combination, either for domiciliary treatment or clinic work, would be conceded. It was the necessary outcome of the growing complexity of medical work. It was the logical corollary of the established principle of hospital practice. It was a means of extending the known benefits, which patients in a charity foundation obtained as a matter of course, to private patients who were able to pay their way. In practice certain difficulties might arise: (1) The cost of establishing an efficient private clinic might be so high as to prevent a combination of capable doctors establishing their clinic on their own resources, and they might be tempted to accept lay association in finance, which might mean lay control or direction. The lay element would desire financial success, and the temptation to some form of advertising would be difficult to combat. Difficulties akin to this had arisen in connexion with establishments which were originally founded as quasi-medical institutions and now combined medical work with facilities for legitimate entertainment. A risk like this could be guarded against by a legal deed of constitution for each clinic before it was set up. (2) If powerful combinations became numerous they might exert an inhibitory influence on the younger members of the

profession who could not or would not seek admission to existing combinations. Possibly existing combinations might be powerful enough to prevent the establishment of new combinations, and thereby act detrimentally on the development of professional knowledge and skill. Possibilities such as these foreshadowed a risk of professional competition far more serious than anything now existing between individual practitioners or partnerships, and it was difficult to see how it could be guarded against. (3) Some might think there was a risk that the commercial aspect of a costly clinic would cause patients to be exploited for profit. That risk was present in any form of practice, individual or combined, and there was no safeguard against it other than a high standard of integrity in the profession. As long as the standard remained as high as it was to day the risk was minimal, and there was no reason why it should not be maintained. In conclusion, Mr. HARMAN cited some actual expressions of intelligent patients in describing their experiences to him, which showed with what favour they viewed these arrangements.

Mr. W. H. CLAYTON GILM, speaking as a surgeon, declared that the existing system was most unsatisfactory to him. He believed that the phrase of a previous speaker, "mental myopia," excellently described the condition of some of the workers in laboratories who were not brought into contact with cases clinically. Specialism did narrow the view. At one end of Harley Street he thought there was a tendency to talk of ileum stasis, and at the other end a tendency to note duodenal irritation! If cases were consulted over, not only by the surgeon and physician, but by the radiographer and pathologist, many avoidable mistakes would not be made. The custom of sending a patient—or, rather, a piece of the patient—without any clinical report to the expert was utterly wrong. It resulted in what might be called the suggestion error in diagnosis. These difficulties would be overcome if a clinical system were initiated whereby the specialists in different departments met and consulted and realized their own mistakes. On the operative side every one would agree that the smoothest operations were done in hospital, where real team work was available. How different was the condition obtaining in many of the nursing homes! It had to be remembered that no operation could be prophesied as a perfectly simple one. These reasons made him support most strongly the provision of private clinics. If a clinic system were introduced and did its job well, he had not the slightest doubt that the public would wear a path to its door.

Mr. W. S. DICKIE discussed in considerable detail the cost of setting up an institution for receiving private patients. In his view the ideal hospital for private patients might be constructed at a capital cost of not more than £500 a bed, and probably less. He discussed also the running costs, and his figures as he worked them out showed that a good private hospital might be run at seven guineas per bed per week.

Dr. A. F. HURST described the private clinic which he has set up twenty miles from London. In his view there was no question but that the patient needing elaborate examination gained considerably by the establishment of such a clinic. An inclusive fee made it possible to carry out many examinations, routine and otherwise, which they would be loath to make if each separate examination entailed an additional cost to the patient, and it had been remarkable what unexpected diagnoses they had reached as a result of these extra examinations. A clinic of this sort should be regarded as a place where there was a prolonged consultation. The saving of time to the medical man was very considerable because the work was all in one building, and there was no necessity to fit in various appointments at different places. Time was also saved from the patient's point of view, because within a week, even in the most complicated case, a definite diagnosis should be made if such diagnosis was possible at all. The presence of a resident medical officer was of enormous advantage because he took over a great deal of the routine work, and also was available to examine the patient and check the patient's description of his symptoms at any time, day or night. Dr. Hurst quite realized that the primary object of such an institution was diagnostic, but there were certain patients who ought to have their treatment under the same absolute control from day to day.

Dr. G. C. ANDERSON, who said that he spoke privately and not as an official of the British Medical Association, was quite sure that any movement on the lines of the private clinic system would be welcomed by the general practitioner. He urged the advantage it would be to a general practitioner to send a patient to a private clinic and there obtain a complete history report, with, most probably, an accurate diagnosis, owing to the ancillary aids to examination, combined with the ordinary clinical methods. Without such assistance the general practitioner might in the first instance direct the patient to a surgeon only to be told that the case was purely a medical one, or, again, that the surgeon must consult the radiographer. The fees charged at a clinic could be more moderate than the present fees charged by individual consultants because by combination the expenses would be lessened. Dr. Anderson sketched the possible constitution and working of a team. Each member might carry on his usual private practice at the clinic, where he would always have at hand a second opinion. Each member of the team might draw his own fees from the patients who consulted him at the clinic in a private capacity, but if any patient were sent by an outside practitioner to the clinic for general diagnosis the fee received for such diagnosis should go into the central pool, upon which would fall the burden of the upkeep of the establishment. The expenses necessary for the conduct of the clinic would be met out of this central fund, and the practitioners would thereby be enabled to carry on their private practice without any expense at all. Any surplus from the pool could be divided yearly among the members of the clinic. As for treatment, if a patient were treated in a nursing home attached to the clinic payment should be made in the usual way, the nursing home charges going towards the upkeep of the home, whilst the surgeon's or physician's fees would be paid direct to the individual who had undertaken the treatment. It would be an advantage to have a medical assessor attached to the clinic, to whom all patients other than those who wished to see a particular member of the team might be directed in the first instance. To be a success a private clinic should be conducted on such lines as would secure the hearty co-operation both of the general practitioner and of the consulting branch of the profession; the fact that such clinics existed should be communicated to the profession only in the usual way. Once the public was asked to aid in the financing of a nursing home the question of advertising was bound to arise, and he felt strongly that the control of private clinics, whether for diagnosis or treatment purposes, should be entirely in the hands of medical men.

Sir THOMAS HOBBS then proposed a resolution:

That in the opinion of this meeting the time is ripe for the formation of group clinics in this country, and that sympathetic encouragement should be given to them by the profession and by its governing bodies.

Dr. C. O. HAWTHORNE suggested that it was inadvisable that such a resolution should be put to the meeting before the subject had been thrown open for general discussion; all the speakers had been those previously advertised to take part. He suggested that the discussion be adjourned to a convenient date.

Sir THOMAS HOBBS fell in with this view, and it was agreed to hold a further meeting for fuller discussion, after which the resolution would be submitted.

THE USE AND ABUSE OF SCIENTIFIC MEDICAL LITERATURE.

A LECTURE which had its humorous touches was delivered at the Institute of Pathology and Research at St. Mary's Hospital on June 16th by Professor W. Bulloch, M.D., F.R.S., whose subject was the use and abuse of scientific medical literature. Professor Bulloch did not spare the frailties either of editors or contributors, and he appeared to think that medical journals still left a great deal to be wished for. His subject was suggested to him by a conversation he had with a house surgeon, who was proposing to write a paper on injuries of the upper extremity. Professor Bulloch remarked that this was an unusually comprehensive theme, and that if he confined himself to the last phalanx of the little finger he would probably

After a reference to prevention associated with industrial conditions, and to the report of the Health of Munition Workers' Committee, Dr. Addison said that it could scarcely require argument that in a definite effort to improve and develop our preventive health services, not only the goodwill and sympathetic co-operation, but also the direct counsel and advice of those whose business it was to understand these questions was essential. What form this should take was a proper subject for discussion in detail, but the medical profession in the past, through its various associations and societies, had proved itself well able to arrange for such discussion, and he was sure it would do so in the future. He reiterated the need for well-considered effort in such directions as the spread of useful information and instruction, the provision of better housing conditions, the encouragement of research and inquiry, not only into the more strictly scientific aspects of medical problems, but in the field of employment and industrial conditions, and the improvement of facilities for early diagnosis and treatment, aided by better organization and direction of the agencies charged with responsibility in these matters.

In reply to a vote of thanks, which was accorded to him by acclamation, Dr. Addison said that some parts of his lecture were the result of experiences in public life not always gained in the easiest way. It might seem a far cry from the scientific application of medicine to the question of 16,000 different rating authorities, but all these factors were involved. The first step in the national prevention of disease—namely, the consolidation of the State departments—had been carried out, but the second step awaited the active co-operation of the medical profession in preventive directions. If society had had available in some practical form during the last fifty years the guidance of the medical profession in the prevention of disease a much larger advance towards national fitness would by now have been made.

SCHEME FOR A POST-GRADUATE MEDICAL SCHOOL IN LONDON.

REPORT OF THE MINISTRY OF HEALTH'S COMMITTEE.

The Report of the Post-Graduate Medical Committee, appointed by Dr. Addison, then Minister of Health, last January, to investigate the needs of medical practitioners and other graduates for further education in medicine in London, and to submit proposals for a practicable scheme for meeting these needs, was issued on June 18th. The Committee was constituted as follows:

The Earl of Athlone, G.C.B., Chairman.
Mr. H. J. Cardale, M.B.
Sir Wilmot Herringham, K.C.M.G., M.D.
Sir George Makins, G.C.M.G., F.R.C.S.
Sir George Newman, K.C.B., M.D.
Sir Robert Newman, M.P.
Sir Edward Penton, K.B.E.
Sir E. Cooper Perry, M.D.
Mr. J. Dill Russell, M.B., F.R.C.S.
Dr. T. W. Shore, O.B.E.

The Report begins by giving a short review of the provision hitherto made. After a reference to the special clinical or laboratory courses arranged from time to time at the undergraduate schools, and attended chiefly by old students each at his own school, a sketch is given of the story of the Medical Graduates' College and Polyclinic, and of the work of the Fellowship of Medicine and Post-Graduate Medical Association since 1918. The action of the Fellowship in arranging courses to meet a sudden and clamant demand which arose after the armistice is praised, and it is noted that the experiment showed the nature of the demand for post-graduate teaching and, by actual experiment, the difficulties by which the position is surrounded. A brief account is given of the work of the West London and the North-East London Post-Graduate Colleges, of the London School of Clinical Medicine, and of certain special hospitals.

Some comments on the ordinary medical curriculum lead up to the affirmation that "the undergraduate course of training alone does not at present equip men and women to practise their profession in a fully efficient way," so that provision is needed for post-graduate instruction to amplify and consolidate what has been learnt prior to

qualification. Additional training and the acquirement of a sense of responsibility immediately after actual qualification being recognized as essential, the opinion is expressed that the only effective way of bringing such opportunities within the reach of every recently qualified doctor competent and anxious to take advantage of them is to increase considerably the number of resident appointments and clinical assistantships. The number of students who qualified from the London medical schools in the year 1919-20 was 579, and it is thought that the number qualifying in any year in the immediate future may be estimated at 500. Though the teaching hospitals cannot provide resident appointments and clinical assistantships for anything approaching this number the Committee considers that the Poor Law infirmaries, the special hospitals, and the general hospitals without medical schools, can be utilized for the purpose.

THE NEED FOR POST-GRADUATE INSTRUCTION AND THE EXTENT OF THE DEMAND.

The Committee considers that the graduates requiring post-graduate instruction may be divided into seven categories:

(a) Graduates who have recently qualified; their needs have been briefly noted above.

(b) General practitioners of some years' standing who require general courses in medicine and surgery. The courses must be simple, practical, and so arranged as to minimize the calls upon the practitioner's time, opportunity and resources. He may wish to have in concise and concentrated form very much the same kind of instruction as the undergraduate is given at the bedside, but he does not wish to attend the same class as the undergraduate. "This," the Committee says, "is natural enough, and we are convinced that any post-graduate instructions, whether of this particular kind or any other, must be organized quite separately from undergraduate work. By this we mean that at the least it must be given at a different time, if not at a different place."

(c) General practitioners who seek instruction in special subjects; they want to keep abreast with latest advances in specialties in which they are interested, and are anxious to attend first-rate instruction at some special hospital or department. "To an increasing extent," it is said, "doctors are working in co-operation, partners take up different specialties in addition to their usual routine duties, so that collectively they can deal with cases . . . to the greater benefit of their patients, and without as much recourse to a consultant as has been the custom."

(d) Graduates from home and abroad who need instruction immediately after qualification, with a view to a higher degree or diploma, such as the M.D., or the M.S., or the F.R.C.S., or the diploma in public health, or that in tropical medicine. With regard to the latter the Committee points out that provision is already made, but it considers that instruction in public health should be better organized. In 1920, it is stated, 120 persons were preparing for the D.P.H. at five of the London schools, and all the other schools undertake to provide instruction if asked for. This is considered to be uneconomic, and it is suggested that an Institute of State Medicine should be formed in direct connexion with the University of London. In addition to providing courses necessary for the diploma in public health the institute might arrange for instruction in forensic medicine, in toxicology, and in industrial medicine, as well as in the relation of the practitioner to the State, his fellow practitioners, his patients, and the community at large. Such a course should be given by a general practitioner of experience. It would be of service to undergraduates who desire appointments or clinical assistantships and are about to be faced with the difficulties of private practice and the complexities of the insurance system.

(e) Officers in the naval, military, Indian and Colonial Medical Services would find civilian post-graduate instruction useful.

(f) Graduates who require facilities for extended medical research find at present little satisfactory provision made for them; the Committee is of opinion that further facilities should be afforded, but in the main at the undergraduate schools.

(g) Graduates from abroad falling into categories (b), (c), and (f) suffer from the lack of organization in London to meet their needs.

Assistance for General Practitioners.

It is pointed out that doctors in general practice, particularly those in category (b), might encounter difficulty in finding time to attend post-graduate courses; especially will this be true in the case of those working in rural areas, who will find it impossible to attend whole-time courses unless a locumtenent of a reliable and satisfactory kind can be obtained. It is suggested that the creation of a "Panel of Substitutes" among recently qualified practitioners would serve the double purpose of providing locumtenents and of encouraging newly qualified persons to seek resident appointments. The panel (or register) of substitutes would be kept by the central post-graduate office. At the same time it is recognized that the young graduate may have difficulty in meeting his expenses, and the suggestion is made that eventually State aid might be given to supplement the emoluments, if any, attached to resident posts or to clinical assistantships. On the other hand, the Committee has considered certain suggestions for offering inducements to general practitioners to attend post-graduate courses, by giving a certificate after successful attendance, by paying the fees of the courses, or even by raising the capitation fee of insurance practitioners on condition that they attended courses periodically. The Committee does not approve "these adventitious aids." It thinks that the man worth having will go to the post-graduate school "out of pride in his work and his profession, if only it is made practically possible for him to do so without encroaching on his meagre annual holiday, which is probably more essential to his efficiency than further instruction." It is, however, suggested that it would be reasonable to provide a locumtenent free to the practitioner attending a course at periodic intervals.

CENTRAL POST GRADUATE HOSPITAL AND SCHOOL.

The Committee recommends the institution of a post-graduate medical school, attached to a large and well equipped hospital, for practitioners able to devote from one to three months to general instruction, for practitioners desiring further knowledge in special subjects, for officers in the services enjoying study leave, and for graduates from overseas. The school would be the centre of a great teaching organization, in which the special hospitals of London, the Poor Law infirmaries, and the medical schools with their clinical units and research departments, would all find their place. As an integral part of the organization there would be a bureau or central office, established under a committee of management, to co-ordinate the whole system, and with the central office would be included a library, a hostel, and all things necessary to afford full facilities for social intercourse.

The central institution for post-graduate instruction, with its hospital, should be situated in a central district easy of access. The hospital should be equipped in up-to-date fashion, and should have at least 300 beds devoted in the main to medicine and surgery, a comparatively small number being set aside for the chief specialties, so as to give completeness to the teaching in the out-patient departments, which should be very fully equipped. Midwifery and fevers should be studied in the special hospitals, and other special hospitals would be brought into the scheme for the benefit of post-graduates anxious to qualify themselves to follow the several specialties. The general wards of the post-graduate hospital, comprising about one hundred beds for medical and surgical cases respectively, might, it is suggested, be divided into three services, the remaining 100 beds being allocated for special diseases in some such proportion as follows: Ophthalmology, 12; skin diseases, 12; gynaecology, 24; children's diseases, 12; venereal diseases, 6; neurology, 12; laryngology, otology, and rhinology, 12; for observation and septic cases, 12. It would be essential

to have a well-equipped pathological department to work in conjunction with the wards; it would be primarily concerned in giving full opportunity for studying the latest methods of examining blood, sputum, etc., and of applying the usual tests, but it might provide accommodation for a few graduates wishing to carry out research in some particular branch of pathology. The general features of the plan proposed are shown in the accompanying diagram.

The Conduct of the School.

Medicine.—Instruction would be given daily in the mornings in the out-patient department by the assistant physicians; in the afternoon the physicians would take classes in the wards in the usual manner. On one day a week all the physicians might combine to give demonstrations and discuss selected cases in the wards for the benefit of all attending graduates. The resident house physicians, who would be of senior standing, would receive an honorarium for teaching, and would be responsible for some share in the training of the graduates in attendance.

Surgery.—A similar procedure would be followed.

The follow-up departments would be organized under the physicians and surgeons who to this extent at least should share in the out-patient work.

Special Demonstrations.—Late afternoon sessions (5 to 6.30 p.m.) should be arranged for special demonstrations by distinguished consultants not on the regular staff of the hospital. A consultant in medicine or surgery would give one demonstration a week for ten weeks, but in some of the special subjects it might be unnecessary to provide more than two or three demonstrations. These afternoon demonstrations would be given by the leaders in the subjects, and arrangements might be made during university vacations for eminent specialists from the provinces and Scotland, or from overseas and foreign countries, to share in the work. The beds at the central hospital allotted to special subjects might be used for these demonstrations, but it would also often be practicable for the specialist to bring with

him cases to illustrate his exposition or to hold demonstrations at his own hospital. General practitioners living at no great distance and able to attend only one or two afternoons a week might take advantage of these special demonstrations. Courses with practical instruction, should be arranged in general and chemical pathology, bacteriology, and serology. Comparative pathology would be a proper subject for post-graduate study should the university be able to carry out the proposals put forward for the establishment of an institute of comparative pathology in conjunction with Brown's Animal Sanatory Institution and perhaps the Royal Veterinary College.

Therapeutics and Applied Anatomy and Physiology.—Courses in these subjects might be arranged at the central school, and pharmacology might be treated from a post-graduate point of view by means of special courses elsewhere under arrangements made by the central school.

Special Hospitals.—It is recommended that the great special hospitals should be closely associated with the central hospital and that the departments of the undergraduate schools should be regarded as special hospitals for the purposes of the scheme. Provision for dental training, would be made at the Royal Dental Hospital, and at existing dental departments attached to the general hospitals with teaching schools.

Staff of the Central Hospital.

The Committee recognizes that the staffing of the central hospital and school presents difficulties, especially if, as is considered desirable, an existing hospital and undergraduate school is converted into a post-graduate school. At the same time the difficulties are not considered

fundamental, and one at least would be diminished if the centre chosen for post-graduate instruction is already a school of the University of London, for the Senate is not likely to raise any objection to its continuance as such, even though its activities were limited to post graduate work and to research. In this case it would continue to be managed as at present, but the general control of the system of post-graduate education would be assigned to the committee of management of the central office described below. The Committee is of opinion that the conversion of an existing hospital into a post-graduate school is the best way of forming a . . . and points out that if the post-graduate centre achieves the success that is confidently hoped, it would be a unique institution with which it would be a high honour to be associated. If an existing school were converted the present staff would continue to serve it, strengthened as far as necessary by any suitable additions. It is, however, considered desirable that one of the three services in medicine and surgery respectively should be placed in charge of a physician or surgeon who is not a regular member of the hospital staff; he might be a distinguished past or present member of the staff of one of the undergraduate schools, and the duty might be taken in rotation for a period of three months by a series of physicians and surgeons.

Details of Staff and Finance.

On the assumption that the hospital service would be provided by the governors on the same scale as at undergraduate hospitals the following suggestions are made with regard to the constitution of the staff and the remuneration of its members.

Medicine and Surgery.—Three physicians or surgeons each receiving an annual honorarium of 100 guineas; three assistant physicians or surgeons with an annual honorarium of 200 guineas; three resident house officers with a salary of £200 a year with board and residence. The total for each service would be about £1,500 a year.

Pathology.—A full-time professor debarred from private practice and receiving a salary of £1,200 to £1,500, together with superannuation provision, would be required. As the subject would include bacteriology and serology, chemical pathology, morbid histology, and post-mortem examinations, full-time lecturers would be required to deal with branches of the subject other than that to which the head of the department devoted himself. The department would provide for instruction of post-graduates and for some research work; its total annual budget, including laboratory maintenance, would be about £4,000.

Special Departments.—A physician or surgeon would be required in each special department, and provision should be made also for teaching therapeutics and applied anatomy and physiology. The estimated cost of these departments and branches is £2,500.

Special demonstrations would be paid for at the rate of about ten guineas a demonstration; the cost it is estimated would be £2,000 a year.

Associated Hospitals.—Payment of the teachers at the special hospitals associated with the central hospital would be regulated by the extent of the demand, but it is estimated that an annual outlay of £1,500 would be required.

Superannuation.—The contribution of the school to the federated superannuation system of the universities on behalf of the full-time members of the staff of the post-graduate school would be £1,000 a year.

The total annual cost of the staff would thus be approximately £14,000.

Central Office.—The establishment of a central office easily accessible from the central hospital is recommended. It should be under the charge of a whole-time principal officer with a medical training, working under a committee of management. This committee should be appointed in the first place by the Privy Council, and should be . . . of general practitioners and the principal . . . The salary of the principal officer should be £1,500 a year, . . . he would be provided with an adequate clerical staff. In addition to providing accommodation for the principal officer and his staff the central office should be so arranged as to serve as a convenient meeting place for post-graduates; it would contain a library, a reading room, and a restaurant; it would be desirable to have a hostel also. It is estimated that the annual expenditure would be £4,000.

Financial Summary.

If the recommendations of the Committee were carried out a total annual revenue of £28,000 would be required—namely, for the teachers £14,000, for the central administration £4,000, for the Institute of State Medicine £10,000. There are only two sources from which this income can be derived—namely, the State or private endowment; local support from rates, the Committee points out, could not be expected for a series of institutions of a national character,

and "the course fees paid by post-graduates should, we suggest, be allocated for capital purposes." If the school and the institute were constituent parts of the University of London, as the Committee recommends, they would be eligible for inclusion on the list of grant-aided university institutions, and the Committee hopes that an annual grant of sufficient amount will be favourably considered by the University Grants Committee and the Treasury. If an undergraduate school were converted the grant at present given to that school would provide in part for the annual grant without additional cost to the State. In addition to the annual revenue considerable capital outlays for initial equipment and adaptation of premises for the school, the central office, and the institute, would be required. The Committee expresses the hope that the University Grants Committee might consider the possibility of making a capital grant for initial equipment and for social purposes on the basis of £ for £ contributed from other sources.

Provincial Areas.

The reference to the Committee did not instruct it to make recommendations with regard to provincial areas. While the Committee considers that the plan outlined will serve the purposes of a much wider area than London itself, there will remain a provincial demand to be met by the universities at the great centres, and they have already taken the matter into consideration.

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on June 14th twenty-seven cases were considered and £382 voted to twenty-three applicants. The following is a summary of some of the cases relieved:

Widow, aged 42, of M.B.Dublin who died in 1915. Applicant had nervous breakdown two years ago and sold her furniture to pay expenses, and only within the last few months has she been well enough to try to support herself and children. She receives £25 subscribed by medical men and invested with the Public Trustee, £30 from Devon and Exeter Medical Society, and £50 from a brother-in-law. Voted £18 in two instalments.

Daughter, aged 67, of M.R.C.S.Eng. who died in 1878. Three daughters were left to support themselves; one died recently who helped with the house. Their sole income is derived from letting apartments. Applicant and her sister, owing to indifferent health, find the work very trying. In 1910 and 1911 the Fund helped this case to the extent of £22. Voted £18 in twelve instalments and a special grant of £6.

Widow, aged 63, of L.R.F.P.S.Glasg. who, when the war broke out, went as a surgeon on transports engaged by different shipping companies, and not coming directly under the Admiralty was not entitled to a pension. Applicant is an invalid. Her son allows her £1 per month; the youngest daughter is out as a cook, but unable to help her mother financially. Voted £12 in . . .

Widow, aged 45, of L.S.A.Lon. funeral expenses and debts out of . . . so little left that she applied to . . . £20 pending the settlement of her father-in-law's estate, . . . expected to realize about £60 per annum. The eldest girl earns 14s. per week and board; the youngest is undergoing three months' training as a shorthand-typist, the fees being paid by a neighbour. Voted £10.

Daughter, aged 36, of L.R.C.S.Edin herself by literary work, but owing to a nerve . . . unable to carry on work, and was dependent c . . . under the notice of the Charity Organization Society, who applied to the Fund on her behalf. She was found to be very ill and near starvation. Another society sent her away for six weeks to regain strength, and ask for a grant towards the cost. Voted £15.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

THE Labour Department of the United States has equipped a number of automobile dispensaries for child welfare work in country districts; each dispensary has a staff consisting of a woman doctor, nurse, driver, and conductor.

THE French Government announced recently that a premium would henceforward be paid for children born in France. In the provinces 300 francs will be paid for third infants, the scale being gradually increased to 650 francs for the tenth child; in Paris the premiums will be increased 50 per cent.

British Medical Journal.

SATURDAY, JUNE 25TH, 1921.

THE POST-GRADUATE SCHOOL REPORT.

As was to be expected from the constitution of the Post-Graduate Medical Committee, its report is a workmanlike document which makes certain definite proposals and is free from superfluities; we could, indeed, have wished that it had discussed one or two points more fully. It presents a scheme for meeting the wants of general practitioners and other post-graduates who are willing to devote a definite period to whole-time instruction of a general or specialist nature; it definitely recommends that for the proper provision of the necessary facilities a post-graduate medical school should be instituted in a central part of London and that a large and well-equipped hospital should be attached to it. In making this recommendation the Committee arrives at a conclusion which was reached by the Fellowship of Medicine more than a year ago; the Committee, indeed, pays a high compliment to the amalgamated Fellowship of Medicine and Post-Graduate Medical College when it says that one great service rendered by the courses instituted at the beginning of 1919 was to show the nature of the demand for post-graduate teaching, and the extent and variety, demonstrated by actual experiment, of the difficulties with which the position is surrounded. One of the difficulties, as has all along been realized, is that the possible attendants at a post-graduate school will not all want the same sort of instruction and opportunity. The Committee, indeed, as will be seen from the full account of the report given elsewhere (p. 942), makes out that there are seven different classes of post-graduates, although it must be admitted that the wants of some of the classes do not differ fundamentally from those of some others; as, for instance, (a) graduates who have recently qualified, and (b) graduates seeking a higher degree or diploma.

Another difficulty is that, to put the matter rather crudely, the staff of no one hospital can, under any conceivable conditions, be strong enough to be representative of all that is best in London. The Committee seeks to meet this objection by two suggestions, both ingenious and both, we believe, feasible. It will be observed that the Committee proposes that the hospital of the post-graduate school should have at least 300 beds, of which 100 would be for the medical service, 100 for the surgical service, and the remainder divided in certain proportions among various specialties. To bring in teachers not directly attached to the staff of the hospital it is proposed that the 100 medical and the 100 surgical beds should be divided each into three services, and that at the head of one of these services in each case should be a distinguished past or present member of the medical or surgical staff of an undergraduate school, who would take his turn in rotation for a period of three months. In the next place it is suggested that special demonstrations should be given by distinguished consultants not on the regular staff of the hospital; each would give one demonstration a week, for ten weeks as a maximum, the hour fixed being, for the convenience of general practitioners in the neighbourhood, late in the afternoon. The scheme presupposes proper medical

school buildings, with lecture rooms and laboratories. It is considered possible that the specialist giving the demonstrations might bring cases to illustrate his exposition to the Post-Graduate Hospital or might hold his demonstration at his own hospital—whether a special hospital or a general hospital with a medical school—the demonstrations in the latter case being so timed as not to clash with undergraduate instruction. Beds assigned at the Post-Graduate Hospital for special diseases might, however, be utilized, and the scheme contemplates the possibility of eminent specialists from the provinces and Scotland, or even from overseas dominions and foreign countries, taking their share in the work during university vacations. It is proposed to pay fees for the demonstrations, to give the physicians and surgeons of the post-graduate hospital an honorarium, to pay the residents' salaries, and to engage whole-time professors and whole-time lecturers in the department of pathology. The cost of all this would, it is estimated, be £14,000 a year, and the central office would cost £4,000 a year. In addition some capital expenditure would be necessary, which might be considerable unless it were possible to take over an undergraduate school as a going concern. There is general agreement that there are too many undergraduate medical schools in London, though when it comes to selecting the particular school which is superfluous, agreement ceases; still, as the Committee points out, the post-graduate centre, if it achieves the success that is confidently anticipated, will be a unique institution with which it would be a high honour to be associated.

The report does not say what is to happen to the West London Post-Graduate College, or the North-East London Post-Graduate College, and we cannot suppose that they will allow themselves to be snuffed out. The Fellowship of Medicine might continue to do the social work, particularly among overseas or foreign visitors, for which it was instituted. The plan for "a panel of substitutes," to consist of recently qualified practitioners who would act as locumtenents for practitioners attending post-graduate classes, is interesting and ingenious. The Committee thinks it hardly possible, however, that it could be realized without a subsidy, direct or indirect, and were the rest of the scheme to be delayed on this account it would be regrettable.

When we ask ourselves what prospect there is of the recommendations of the Committee being carried out, we cannot but regret the introduction into the scheme of a plan for an Institute of State Medicine. We do not doubt that in the present temper of the country and of the House of Commons, objection to the scheme will be taken on the ground of expense. The proposal with regard to an Institute of State Medicine adds something like 50 per cent. to the total annual expenditure the recommendations of the Committee would involve, and we are decidedly of opinion that the establishment of such an institute, although theoretically advisable, is, as a matter of practical politics, not urgent. Excellent training for the examination for the diploma in public health can be obtained both in London and other centres, and we have not heard that candidates have ever experienced any difficulty in obtaining the facilities they needed.

It is a reproach to London, as everybody must be growing tired to be told, that it has not got a post-graduate medical school worthy of it. We may well be grateful to Dr. Addison for appointing the committee which, under the guidance of the Earl of Athlone, chairman of the Middlesex Hospital, has presented the Government, Parliament, and the public with a very clear statement of the situation and a

bold plan for remedying deficiencies which have long been the cause of anxiety to those jealous for the honour of British medicine. We earnestly hope that the recommendations of the report may early receive the attention of Dr. Addison's successor. The matter has two aspects, the national and the international, and in respect of the latter time is of great importance. Many teachers who themselves frequented Vienna and Berlin are sending foreign, and perhaps also overseas, post-graduates to these cities, whereas it is to the interests of this country from many points of view to attract them to London. Already there has been two years' delay: perhaps it was inevitable, but further delay is not inevitable. We hope also that the University of London will show itself alive to the necessities of the situation, and that the Senate will be disposed to encourage the conversion of an undergraduate school into a post-graduate school.

A NEW STUDY OF APHASIA.

II.

In a preceding article some account was given of the position to which the theory of aphasia had been advanced by the labours of Hughlings Jackson and Pierre Marie, and it was shown how Head's examination of Jackson's opinions brought us back to Locke's view that language is the use of articulate sounds as marks or signs of ideas within a man's own mind whereby they can be made known to others. We propose now to consider some of Dr. Head's own most recent observations.

During the war he examined many young and healthy patients who, from head wounds, had developed slighter and more specialized defects of speech than are met with in disease. They were for the most part intelligent and anxious to improve. Even had it not been clearly appreciated before, it would have been obvious from observation of this class of patient that there is no single psychological function or faculty corresponding to "speech." Dugald Stewart saw this when he remarked that "words only convey hints." Gradually societies of men agree amongst themselves to limit the scope of hints conveyed by particular words and phrases until a conventional dialect is arrived at. Words have no natural signification; the idea which each stands for must be learned and retained by those who would exchange thoughts. But words are not only the names of ideas in the mind: they are also the signs of the connexion that the mind gives to ideas one with another.

No lesion can affect speech and speech only. Cerebral injury only disturbs the complex act called "speech" by interfering with certain physiological processes which underlie the use of language. As Head shrewdly put it, "we should as soon expect a special centre for eating as for speech." This idea will come as rather a shock to those who have been brought up on the current teaching, with its terms "motor" and "sensory" aphasia, "alexia," "agraphia," and "amnesia verbalis." We had almost come to regard the faculty of speech as consisting of word-clusters pocketed away in definite centres in the brain which could be destroyed piecemeal and independently of other cerebral faculties. Head reminds us opportunely of Hughlings Jackson's division of language into emotional and intellectual. It is eminently helpful and practical; once grasped it is never forgotten and proves a key to unlock many doors. Emotional utterance is phylogenetically developed earlier and in the presence of injury or disease is retained longer. It enables man in common

with the lower animals to exhibit states of feeling. Intellectual language is developed later and consists in a power to convey ideas or propositions by gesture, vocal sounds, and by written signs. When the physiological processes which subserve the complex act of speech are disturbed, words, numbers, pictures, and every function which depends upon the use of symbols in constructive thought, may be affected. From what has gone before the reader will be prepared to learn that Head does not allow that language can be considered to be a function apart; it may suffer impairment in common with any mental process which demands for its performance exact comprehension, voluntary recall, and perfect expression. We cannot set definite limits to the processes involved, we do not know them. Head suggests that the whole group of allied processes might be spoken of as "symbolic thinking and expression," because it is mainly the use of words, numbers, and pictures which suffers in aphasia and kindred disorders. He warns us against regarding the term as in any way defining the group of processes affected and would have preferred some entirely indifferent term if one had been available. Hughlings Jackson had used the word "propositionize" to represent the mental processes which precede the intelligent use of language. Loss of language for both Hughlings Jackson and Head is, as we understand them, primarily a defect in formulating ideas, and secondarily a defect in correlating ideas to men's arbitrary signs, whether spoken or written words or gestures.

Locke discussed some of the difficulties to be encountered in analysing the nature of language. He pointed out that in the first place the ideas words stand for may be very complex, and made up of a great number of ideas put together; and that, in the second place, the ideas they stand for may have no certain connexion in nature, and no settled standard by which to rectify and adjust them. Thirdly, he observed that the signification of a word may be referred to a standard which is not generally or easily known, and finally he maintained that the signification of the word and the real essence of the thing may not be the same. Locke offers the definition we are looking for: "Words are the voluntary and unsteady signs of men's own ideas." Head's phrase "symbolic action" seems intended to cover all the possible uses of these unsteady signs.

The whole difficulty of adopting Head's views seems to lie in the acceptance of two particular terms: Jackson's "propositionizing" to represent the process of getting ready in the mind a concept or idea in such a shape that it may be communicated to others, and Head's "symbolic action" to represent the utterance of those signs or marks which, if employed according to the conventional dialect of a man's neighbours, will convey to them the idea or sequence of ideas which have been marshalled in his mind. In a concluding article the classification of conditions which Head proposes will be explained.

RESIGNATION OF PROFESSOR SIR HALLIDAY CROOM.

THE Court of the University of Edinburgh, at its meeting on June 13th, received with great regret the resignation of Professor Sir J. Halliday Croom from the Chair of Midwifery and accepted with grateful thanks a gift by the Professor of all the preparations, specimens, apparatus, and diagrams which he had collected during his tenure of the chair. It was known during the session that Sir Halliday Croom intended to resign before the beginning

of another winter, and at the close of his class in the university in March last he bade farewell to the men of the year in characteristically beautiful and thought-laden words. Some parts of this valedictory address were published in *The Student* for May, but it is to be hoped that in its fullness it may be made available for the reading of Sir Halliday's former pupils scattered all over the world. What a teacher has to say of his work after nearly fifty years' devotion to it cannot fail to be interesting; and when, in addition, large numbers of eager undergraduates attended that teaching all these years, interest deepens into absorbing, impressive, and rapt attention. Examples of the Professor's pithy, picturesque, sometimes pungent, and always arresting and memorable phrasing were not wanting in the farewell address. "Obstetrics can never be relegated to a second place in the curriculum. . . . As I have often said to you, in medicine and surgery you can fall back on the advice of your colleagues or on eminent specialists, but in the dramatic incidents of private obstetric practice you must work unaided and alone. . . . You are the lineal descendants of Goodfellow, Simpson, Lister, Christensen, Laycock, Syme, and Bennett. . . . Can I make a stronger appeal than the old words, *Nollese allige*? . . . Let me assure you that to live is sometimes very difficult, but it is never meritorious in itself, and we must have a reason to allege to our own conscience why we should continue to exist on this crowded earth. . . . I am optimistic enough to re-echo Whittier's article of belief, and to make my last adieu to you all in his words, so full of good cheer and of eternal hope: 'Of course the world is growing better; the Lord reigns; our old planet is swinging slowly into full light. I despair of nothing good. All will come in due time that is really needed, and all you have to do is to work and wait.' The class was not lacking in its recognition of Sir Halliday Croom's outstanding merits as a teacher, and in presenting the retiring Professor with a silver-mounted walking-stick and a silver cigar box from the present and from some of the former students, Mr. A. M. MacLachlainn said some true things in a felicitous way. "Coming to your department as to a somewhat dry and unromantic study, we have found you not, certainly, mis-calling technicalities, but, so to speak, handing us a chair, and illustrating the minutiae of your art with aphorisms and modern instances ranging from the peerage to the byre." In speaking of the Professor's constant kindness shown to his pupils, Mr. MacLachlainn provoked a smile with his remark, "Sir, the medical student, like other wildfowl, responds to kindness." The undergraduate, with unerring instinct, laid emphasis, too, upon the outstanding attractiveness of Sir Halliday's lectures when he spoke of their aphoristic and vivid phraseology. Sentences minted in the midwifery class-room have over and over again become current coin in the University. Carlyle may have called man a tool-using animal, and the French have defined him as the cooking animal; but it needed Sir Halliday Croom to describe woman as a being with a Curve of Camus, throwing a sudden spotlight on this modest and retiring anatomical feature, and showing it up as a feature of generic import. Sir Halliday Croom's resignation of the Midwifery Chair has coincided with the completion of his term of office as Chairman of the Central Midwives Board for Scotland, and has involved his departure from the acting staff of the Royal Maternity Hospital; but he is still hale, hearty, full of life, keen of mind, and imbued with what he himself spoke of as the enthusiasm of humanity, and Edinburgh and his colleagues rejoice in his continued presence in their midst. If he finds time hanging heavily upon his hands a volume from his pen on Medical Edinburgh in the seventies of the past century would be a delightful book of remembrance as well as a joy to the lover of those less recent days when John Hutton Balfour spoke of "woody fibre," when Croom Brown (still alive and well at a great

age) set off explosive mixtures in the chemistry class-room, when Hughes Bennett and Laycock saluted one another, when Sir William Turner ruled in the anatomy department and "axed all very nervous pupils," when Sir Robert Christison tried the effect of swallowing calabar bean on an empty stomach, when Spence was said to be somewhat "dismal" in surgery, and Lister was brilliant in invention, when Sir Wycliffe Thoms made a d in prismatic eloquence the beauties of the jelly-fish of tropical seas, and when Sir Alexander Russell Simpson (Sir Halliday Croom's friend and predecessor in the chair) had, perhaps, his own brilliancy a little obscured by the exceeding brightness of his uncle's fame. It is understood that Sir Halliday Croom has expressed abhorrence for anything and everything of the nature of reminiscence; but will he not "take another thought" and give to his many friends the real gift of a sketch of the Edinburgh Medical School in the seventies?

PROTECTION OF RADIOLOGICAL WORKERS.

THE X-Ray and Radium Protection Committee, the constitution of which was announced in the *Journal* of May 28th, 1921, has now issued a preliminary report which we print in full this week, at p. 955. The Committee was set up by a number of metropolitan corporations interested in radiology. The chairman is Sir Humphry Rolleston. In view of the constant demand for guidance from individuals and institutions, it was thought desirable to issue an early statement on the means for the protection of the worker, and the present report accordingly gives an outline of existing knowledge with regard to equipment, ventilation, and working conditions of x-ray and radium departments. After the completion of this, the next pressing part of its work, the Committee will proceed further with the collection of data bearing on the effect of irradiation, with special reference to protection. Researches will be undertaken and further reports published from time to time. It will be observed that the preliminary report opens with the positive statement that the danger of over-exposure to x-rays and radium can be avoided by the provision of efficient protection and suitable working conditions; it is, therefore, the duty of those in charge of x-ray and radium departments to ensure that this provision is made for their workers. Although the Committee believes that an adequate degree of safety would result if the recommendations now put forward in some detail were acted upon, it insists that this protection depends entirely upon the loyal co-operation of the workers in following the precautionary measures advised. The Committee further recommends that periodic tests should be made of the blood of the personnel, so that any changes may be recognized at an early stage. This is necessary because susceptibility to radiation is not constant for all workers, and in the present state of knowledge it is difficult to decide when small variations from the normal blood count become significant.

THE IDEALS OF A BELOVED PHYSICIAN.

IN 1905 Dr. C. N. B. Camac of New York brought out, with the consent and guidance of his old teacher, a volume of *Counsels and Ideals*, selected from forty-seven of Sir William Osler's writings. This attractive collection of *obiter dicta*, representing Sir William's philosophy of life down to the time when he took up the duties of the Regius Professor of Medicine at Oxford, met such an immediate and well-deserved demand that within two years a fourth impression was required. In 1918 the book went out of print on account of the loss by enemy submarine action of a consignment for the American market. During his fatal illness Sir W. Osler had the possibility of a second edition in mind, and now, though with some hesitation from the consciousness that he had to act without the help of his former guide, Dr. Camac,

and the General Medical Council is therefore now free to recognize South African medical degrees which fulfil the prescribed conditions.

CONGRESS OF MEDICAL HISTORY.

THE Congress of Medical History, of which we have already published some particulars, will be opened at the Faculty of Medicine in Paris, by the Minister of Instruction, on the morning of Friday, July 1st. Discussions will take place on that afternoon, and on July 2nd, 4th, 5th, and 6th. The subjects for discussion include the history of hospitals; the diet scale of man, of animals, in antiquity, and in the Middle Ages; great historical epidemics; and the part played by drug dealers in the development of biology. On certain afternoons visits will be paid to various medical institutions and also to the principal libraries, galleries, and museums of Paris. On Friday evening Dr. Henry de Rothschild will give an entertainment at the Gymnase Theatre, when a piece by M. Pascal, entitled "Le Caducée," will be given. There will be other afternoon and evening entertainments, and a banquet at the Palais d'Orsay on the evening of July 6th, when the congress closes.

THE SERUM DIAGNOSIS OF SYPHILIS.

IN the report in our issue of June 11th, 1921 (p. 859), of a lecture given by Professor Georges Dreyer, M.D., F.R.S., on June 2nd at St. Mary's Hospital, on a new method for the serum diagnosis of syphilis, the expression "Professor Dreyer's method" was used. We are asked by Professor Dreyer to make it quite clear that the lecture was mainly an account of the joint work of himself and Dr. H. K. Ward, M.C., and the method should therefore be referred to as the Dreyer-Ward method.

As already announced, the gold medal founded by a Fellow of the Royal Society of Medicine for a member of the medical profession who specially distinguished himself during the previous three years, was awarded to Sir Almroth Wright, who gave an address in acknowledgement last November (BRITISH MEDICAL JOURNAL, November 20th, 1920, p. 797). The medal, which was not ready at that date, will be presented to Sir Almroth Wright at the annual meeting of the Society at 5 p.m. on July 6th.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Public Health Officers Bill.

THIS measure, which was introduced in the House of Commons by Sir Philip Magnus, and passed through all its stages there, is now awaiting second reading in the House of Lords. It had formal first reading on June 7th, and since then a petition against it has been presented by the City of Westminster.

Dentists Bill.

The Earl of Onslow, on behalf of the Ministry of Health, moved the second reading of the Dentists Bill in the House of Lords on June 16th. Having explained the provisions, he said that there was only one matter in regard to which there was any material difference of opinion, and that was as to the form of the Register. The admission of unqualified practitioners, even on the guarantee of experience required under the bill, had been opposed by Sir Frank Colyer, and a different form of register suggested. He had been answered by the chairman of the Departmental Committee (Mr. Acland) upon the report of which the bill was based. The reasons why the Government stood by the report could be explained in Committee. Lord Greville intimated that, as representing the Ivory Cross Society, he would have some criticism to make in Committee.

The Marquess of Salisbury said he believed all in that House were in favour of the bill. There was an element which

needed careful scrutiny. In order to arrive at an agreement Mr. Acland's Committee seemed to have been led, as a *quid pro quo* to the unqualified practitioners, to admit the existing ones *en bloc* as fully qualified dentists. That might be good tactics from a parliamentary standpoint, but it was extremely bad for the people who suffered from toothache, and the peers would have to consider closely whether they were going to allow a number of practitioners, some of whom were little better than charlatans, to be admitted by a stroke of the pen to the full advantages, privileges, and dignities of dentists in order to facilitate the passage of the bill. That appeared to be the point. If there were a good answer they would bow to it, but he suggested that the Government should carefully consider whether a change in the bill in this respect ought not to be inserted.

Lord Knutsford said he was a member of the Departmental Committee, which sat for a long time and took a great deal of evidence. There was no suggestion that all unregistered men should be admitted *en bloc* to the Register. On the contrary, the Committee limited the admission to those men who had been in good practice for five years and could bring evidence as to good character in their practice. They also recommended that those men who had not been five years in practice, but who would submit themselves to a qualifying examination, should also be admitted. They had also received letters and circulars from a certain number of gentlemen, more noisy than wise, who wished to keep out all the unqualified men from the Register. He did not know whether it was realized that by far the greater part of the dental work in this country was done now by these unregistered men, and it would be monstrous to prevent them from carrying on their practice. Moreover, the dental work of the country could not be done unless these unqualified men were allowed to practise. Hence the clause. In those circulars and letters, which their Lordships might have read—or might not have read, but have put in the waste-paper basket for other people to read—there was a suggestion that a special list of these men might be made. A much better way would be that the Register should show the qualifications of every dentist opposite his name, and that those who were unregistered, or were on the Register without qualifications, should have this fact shown opposite their names in brackets. The Marquess of Salisbury spoke of the privileges of being on the Register. There was a good deal more than privilege in it. It meant that the way in which a dentist carried on his profession was controlled; that he was obliged to obey the ethics of the profession; that he could not do this and he could not do that; that he might not canvass and that he might not advertise for work. The Register, therefore, was a controlling influence. What they wanted to insist upon was that there should be no unregistered men operating in the country. Those were the huge advantages of the bill, and unless it passed good men would not go into the profession. If the bill passed it would increase the number of qualified men who would join and secure better treatment for everybody.

The bill was read a second time.

Ireland and the Dangerous Drugs Regulations.—Captain Charles Craig, on June 16th, brought before the House of Commons two alleged grievances in the proposed operation of the Dangerous Drugs Regulations as affecting Ireland, and for that purpose formally moved an address to His Majesty to annul the draft. His first point was as to the position of farmers. Hitherto they had been able to keep a small supply of laudanum for dosing horses and cattle for certain complaints, especially for colic. In future they would have to get a prescription from a veterinary surgeon before they could procure any laudanum. He understood that the Home Office was willing to modify the rule so that the drug could be obtained on some sort of certificate to be given by the police or some other body, but he asked for information. The second point concerned the chemists and druggists of Ireland. Under the law pharmaceutical chemists in that country had a monopoly of dealing with prescriptions, and ordinary chemists and druggists were able to sell poisons of any kind, though not to compound prescriptions. Under the Regulations the drugs specifically mentioned in the Act could be served out only on prescriptions, which meant that the chemists and druggists would lose their rights. It was hard that because of a certain amount of drug-taking in large cities these traders should lose a considerable part of their business. He put it that the same kind of certificate proposed for farmers should be available for them—for the sale of laudanum for instance—and that they should be at liberty similarly to sell patent medicines, such as chlorodyne and zinc ointment, which, he gathered, contained a prohibited drug, and other things which they received from manufacturers. Sir John Baird (Under Secretary for the Home Office) said it was certainly necessary to meet the case of the farmers. The Committee had suggested that this could be done in one of two ways—either by selling laudanum in a denatured form, or else, pending the discovery of some method of denaturing laudanum, by certificates issued to farmers by the local police. It was intended to provide for such issue. In the case of the chemists and druggists such legal opinion as the Home Office had been able to take held that, though the chemists and druggists were prohibited from compounding mixtures, they were entitled to dispense made-up prescriptions of something they had not made up themselves. Moreover, there was a considerable list of drugs which were exempted. Taking these two things together—the exempted drugs as contained in Schedule 2 and the belief that the druggist would be entitled to dispense mixtures containing poisons

which he had not him self compounded—by having the the position was met. On a further question Sir John Baird, as regards the farmers, that the police authorities would not have to state whether a man was entitled to have his name on a form supplied by the Home Office, and would be to the effect that the man was a bona fide farmer or stock owner. That was a matter of fact, not of opinion. Captain Ciar, afterwards withdrew his motion.

The Appointment of Medical Referees.—Mr. T. Gae asked the Minister of Pensions, on June 15th, (1) whether, seeing that the original appointments of medical referees were made before the completion of medical demobilization, these appointments would now again be declared vacant and re-advertised, or whether the original appointments were fixed and permanent appointments of the present holders; (2) whether the appointments of medical referees were now reviewed every six months as originally decided, how many of these appointments have been considered vacant on review and elapsed, and whether the opinion of the local pensions committee is ever asked or considered in these appointments. Mr. Macpherson replied that in the latter part of 1919, when the demobilization of medical men was practically complete, the then existing appointments of medical referees, to the number of 502 were declared and 1,553 new appointments were made, preference being given to those men who had served overseas during the war. All the present appointments were temporary, being subject to one month's notice on either side. While the paramount consideration in making these appointments must be medical, consideration was always given to representations made by local committees. In answer to Mr. Guest, Mr. Macpherson said that the Ministry utilized the services of 1,717 medical referees, whose appointments were part-time and subject to a month's notice. Payment was made at the rate of 5s. per case, except where the examination was in connexion with a claim to alternative pension, when the fee was 10s. 6d. The amount paid in fees to medical referees during the last financial year was approximately £2,500. He did not think there had been a transfer of duties formerly performed by war pensions committees to the medical referees. They dealt purely with the medical aspect of a case, and the local pensions committees dealt mainly with the facts.

Criminal Law Amendment Bill.—Viscountess Astor asked Mr. Chamberlain, on June 15th, whether he had received copies of two resolutions passed at a meeting held in the House of Commons in support of the Bishop of London's Criminal Law Amendment Bill, at which practically every organization interested was represented, promising to abstain from introducing controversial amendments, and whether, in the circumstances, he would give facilities for the passage of the bill this session. Mr. Chamberlain said he had received the resolutions, but could not make a pledge to find time at this stage, though he hoped it might be possible to do so later. Viscountess Astor again pleaded for a definite assurance, remarking that the measure would not involve any expenditure and was one of the bills that the Government could get through. Mr. Chamberlain said that he quite understood the importance attached to it by a very large section of public opinion, and he was anxious that it should be considered by the House this session. Major Claud Lowther asked whether Mr. Chamberlain was aware that the bill was likely to lead to considerable controversy. Viscountess Astor: Only by a certain section.

Scottish Universities.—Mr. Munro announced, at the instance of Mr. McCallum Scott, the decision that the annual financial and statistical reports relating to Scottish Universities for 1919-20 and future years, will be made available for members of the House of Commons in the form in which they appear in the returns from universities issued by the University Grants Committee.

National Health Insurance.—Mr. Jack Jones asked, on June 15th, if the Minister of Health would consider, in view of the large amount of unemployment and consequent distress, the advisability of making an allowance in contributions, under the National Health Insurance Act, so as to prevent a reduction in benefits to those who were drawing allowances under the Act. Sir A. Mond replied that the matter was being seriously considered, in the hope that it might be possible to do some thing in the direction suggested.

Medical Benefit.—Mr. Lyle, on June 20th, asked if there were statistics showing the number of insured under the National Insurance Act who were already in arrears with the maximum total of unpaid subscriptions, which, unless met before October, would debit them from medical benefit in 1922. Sir A. Mond replied that all insured persons remained entitled to medical benefit so long as they continued in insurance, and there was no suspension of benefit on account of arrears of contribution.

Holloway Prison.—Mr. Shortt, in reply to Lieut. Commander Kenworthy, on June 14th, said that no complaint as to the condition of the food served to prisoners in Holloway Prison had been made to the Visiting Committee. Members of the Committee frequently tested the quality of the food and were satisfied with it. Individual prisoners sometimes complained, but otherwise there was nothing to support the suggestion. No complaint had been made of the milk being sour. Mr. Shortt also answered in the negative the question as to the abolition of the hospital.

Medical Officers of the Forces.—Mr. Alfred T. Davies asked, on June 15th, what proportion of medical men whose services were not for examining ex-service men, had had experience overseas during the war, and whether the Minister of Pensions could state the general list of employing a large number of such medical men in the interests of the ex-servicemen from time to time. Major Trench said that approximately 60 per cent. of the medical officers employed in the department in examining ex-service men had served overseas during the past war. It was the practice of the Ministry, other things being equal, to give preference to medical men who had done the qualification named.

Income Tax (Income of Ex-Servicemen).—In Committee on the Finance Bill, on June 15th, Mr. Holmes moved an amendment to Clauses 15, under which Parliament resolved that, as that Section 33 and 34 of the Income Tax Act of 1915 were not continued in force for the year 1920-21, at least not explicitly in force. Under Section 33 of the Act of 1915, any person or company whose profits were reduced from year to year circumstances could claim to be charged on the average of three years ending the year of assessment instead of on the average of the previous three years. Under Section 34, any individual proving that his actual income from all sources was less than 10 per cent. than the income on which he had been assessed on the three years' average, was entitled to be charged upon his actual income and to obtain repayment of the difference. Last year Mr. Holmes moved specifically that the section of the 1918 Act should remain in force. This was defeated at the instance of the Government by a large majority. But it seems to have been left obscure whether in the absence of a definite repudiating provision the sections do not remain in force. Sir Robert Horne stated that there had been six decisions by Comptroller-in-Chief, one way and three another, and none had gone to a court of law. Two hundred claims were pending. In the course of the debate there were protests, more especially against the retrospective part of Sir Robert Horne's proposal, but it was carried by 203 votes to 31.

Retention of Pensions.—Lieut. Colonel the Hon. G. F. Stanley informed Mr. Frederick Thompson that, in the case of both officers and other ranks serving during the late war with a force under the British flag, service should count for retention of pension if the service had been rendered with the British forces.

Deaths Associated with Vaccination.—In answer to Mr. L. Dawson, Sir A. Mond stated that according to the Registrar-General's returns, the deaths registered in England and Wales in each of the last ten years as caused by or associated with vaccination are as follows:

	Registered on Certificate of a Registered Medical Practitioner	Registered on Certificate after Inquest	Uncertified	Total
1911	11	4	—	15
1912	6	4	—	10
1913	6	—	1	7
1914	1	1	—	2
1915	9	4	—	13
1916	2	1	—	3
1917	6	2	—	8
1918	4	—	—	4
1919	5	—	—	5
1920	15	4	—	19

It cannot, however, be stated whether any of the cases in which no inquest was held were reported to a coroner or not.

Outbreaks of Rabies.—Major Barnston informed Captain Sir Hamilton Benn, on June 14th, that the most recent outbreak of rabies in England occurred at Southampton on June 6th and at Salisbury on June 7th. There had been no recent outbreak of rabies in Scotland. In Wales the last outbreak was on September 8th, 1920. As regards Wales the Muzzling Order was withdrawn on May 1st, 1921.

Whole ale and Retail Milk Prices.—Sir A. Boscawen said that the average prices at which contracts had been made for the summer months for milk delivered into London, producer paying carriage, were as follows: May and June, 1s. 2d. to 1s. 3d. per gallon; July, 1s. 4d. to 1s. 6d.; August, 1s. 6d. to 1s. 8d.; and September, 1s. 8d. to 1s. 10d. He understood that the price at which milk was being retailed in London was usually 8d. a quart. On another question, by Mr. Hurd, the Minister said he was aware that in some districts in Somerset farmers were receiving from wholesalers no more than 10d., 8d., and in some exceptional cases, 6d. per gallon for their milk.

The River Lee.—Major Malcom, on June 16th, asked the Minister of Health if he would exercise such pressure on the Lee Conservancy Board as to compel that authority to purify the river. He said that as late as last week the medical officer for Tottenham had reported to his Committee that objectionable matter, consisting of decomposing organic material and oil substances, had entered the river below the Tottenham lock, causing that reach to be highly polluted and offensive. Sir A. Mond replied that he had no information as to the complaints referred to, and he had no power to compel the Board to carry out the work indicated.

Ex-Service Men in Asylums.—Mr. F. Roberts asked, on June 16th, whether when an ex-service man had been committed to an asylum on account of mental injury attributable to the war, the man himself and his next of kin were informed that one of the privileges attached to his having been placed on a private patient footing was that, provided that he could not be proved to be dangerous and unfit to be at large, his next of kin had the right, in accordance with Section 72 to 74 of the Lunacy Act, to direct his discharge. Sir Alfred Mond said it was not desirable to furnish this information on admission, but when a service patient was sufficiently recovered to raise the question of his discharge, he was informed of the legal position and of the steps to be taken by his relatives.

England and Wales.

THE WEST MIDDLESEX HOSPITAL.
The West Middlesex Hospital, situated at Isleworth, was formerly known as the Brentford Union Infirmary. It is built on an extensive site, which includes also the buildings of the workhouse, separate blocks for pulmonary tuberculosis, midwifery, and mentally defective boys. The wards of the hospital are of modern construction, well lighted and ventilated, and diverge from each side of a long central corridor. The wards on one side of this corridor contain 14 beds; on the other side are larger wards of 24 beds. There are three stories to each block. The total number of beds in the hospital is 420, but at present not all of these are available for patients. The number of beds in the workhouse is 880. Recently more of these have been made available for chronic patients and slight cases from the hospital; the total number of patients in the workhouse under the care of the medical staff of the hospital is now about 500.

Although it is now described as the West Middlesex Hospital the institution remains under the guardians of the poor of the Brentford Union. There is an arrangement by which the County Council sends its patients to the tuberculosis block, which has been railed off from the rest of the building. But this block, like the rest of the hospital, is under the governance of the guardians. The medical staff consists of a superintendent and two assistants. There is also a consultant staff, drawn mainly from London, whose services are honorary so far as the Poor Law patients are concerned; but they are paid the sum of one guinea as travelling expenses for each attendance.

The patients consist of Poor Law patients who are considered to be destitute and have to pass through the hands of the relieving officer. But the Ministry of Health allows considerable latitude in the estimation of medical destitution. Consequently many of the patients are by no means destitute from the financial point of view. They are admitted because their means do not permit them to obtain suitable treatment; and those who can afford to pay are charged up to a maximum of £3 5s. a week for maintenance. Recently it has been decided to set apart two wards of eight beds each for a better class of paying patient. These patients will pay four guineas a week for their maintenance, with extra charges on a fixed scale for special services of a consultant or specialist nature, such as consultations, operations, x-ray work, and so on. The paying patients will only be admitted on the recommendation of an outside practitioner, and not through the hands of the clerk to the guardians, and only serious cases, medical or surgical, shall be accepted for admission. Further, it is hoped to institute something of an out-relieving officer; and it is intended that only serious cases, patient nature, at all events for special cases. These paying patients will be treated by the medical superintendent and his assistants, but will have available the services of the consultant staff at the tariff which has been laid down.

In this brief description it will be seen that the arrangements at the West Middlesex Hospital differ in essential points from the ideals aimed at in Bradford; for example, the only attempt at disguising the nature of the institution has been the change of name. The guardians of the poor are the authority responsible for the institution. Except in case of emergency, the patients pass through the hands of the relieving officer. The hospital is not a municipal hospital open to all ratepayers. Inability to pay more than a certain rate for maintenance remains a safeguard against

misuse. With regard to the paying patients, however, the criterion for admission is not so much financial disability as the severity of the condition of sickness or disease. If the patient is sufficiently ill, or requires operation, he will be admitted, provided that his doctor recommends him and the clerk to the guardians is satisfied that he cannot afford to pay specialists' and nursing home fees. The decision as to admission rests with the authorities of the hospital; financial limitation being contemplated to a certain extent, inasmuch as the fees payable for consultant or specialist assistance are on quite a low scale.

The arrangements at this hospital do not seem to be in accord with the expressed opinions of the British Medical Association. The general practitioner is not used in any way except as a safeguard in the admission of patients to the paying wards. The treatment of the patient passes entirely into the hands of the hospital staff, and it is, we understand, considered impossible to make arrangements that patients admitted to the paying wards shall be treated by their own family practitioners. The hospital is not in any sense a primary centre such as is described in the Dawson Report.

There seems little doubt that the hospital, as at present conducted, meets some of the needs of the community. It provides hospital facilities for those who cannot afford to pay the ordinary fees of surgeons and of nursing homes. The facilities provided include nearly all those things which are said to be lacking in the treatment of panel patients and the poorer classes of the community. Both with regard to Poor Law patients and those who will become paying patients in the hospital it imposes limits to prevent abuse by those who can afford to pay. It safeguards the general practitioner by refusing admission to the paying wards except on his recommendation. There are certain other points which should be carefully considered by the medical profession. In the first place the question arises whether the facilities provided at the public expense should be limited to certain sections of the community. At the present time the necessity of limiting expenditure probably renders such limitations obligatory. Should they be maintained when the financial position of the local authority improves? Much has been said about the abolition of the stigma of pauperism. But so long as a distinction of classes is made into those who can afford to pay for their treatment and those who cannot, so long there is bound to remain a stigma, at all events of poverty. The distinction involves the retention of an official of the nature of a relieving officer. He may be glorified by the name of almoner, but in essence his duties will in this respect be the same.

Secondly, so long as the distinction of classes is maintained, are the safeguards to the general practitioner sufficient? On the one hand, the relieving officer should be an efficient check in preventing abuse of the Poor Law side of the institution; on the other hand, the requirement of a doctor's recommendation should prevent the use of the paying wards by persons able to pay full fees and charges. The requirement that the clerk to the guardians shall approve the recommendation will tend to relieve the general practitioner of the risk of incurring odium by refusing to recommend unsuitable patients. The working of these safeguards is likely to be more satisfactory if the local profession is represented by a strong medical committee acting in harmony with the hospital authorities, and ready to judge any hospital scheme for the good of the community. This leads to a third question, which is whether attendance by general practitioners will prove to be feasible in hospitals which serve large populous areas. So far as indication of their opinion has hitherto been given, the great majority of public medical officials regard such an arrangement as impossible. In cottage hospitals it can be made to work. In primary health centres, provided they serve a small area, it is possible that every local practitioner will be able to attend his patients in the hospital, though even here difficulties may arise. In large hospitals of the infirmary type it is not so easy to see how the difficulties would be overcome, and anything which helps us to understand how they may be surmounted is of value. The study of systems such as exist or are proposed in institutions of the nature of Bradford Municipal Hospital and the West Middlesex Hospital should help to elucidate these questions.

Scotland.

PARLIAMENTARY REPRESENTATION OF SCOTTISH UNIVERSITIES.

At meetings of the Unionist Associations of the Scottish Universities held recently a letter was received from Sir Watson Cheyne, Bt., K.C.M.G., one of the members for the Universities, stating that he might be compelled on account of his health to resign at any moment, and that even if he were able to remain in office till the end of the present Parliament he had definitely decided not to seek re-election. He suggested that a suitable prospective candidate should be selected without delay, so that he, Sir Watson Cheyne, might be in a position, if he felt unable to go on any longer, to resign without feeling that he was doing anything harmful to the constituency. It was unanimously agreed that in view of the complex problems of public health with which the House of Commons has now to deal, and of the value in relation thereto of highly trained professional opinion, the services of an eminent medical graduate of one of the Scottish Universities should if possible be obtained. Sir George Andreas Berry, LL.D., F.R.S.E., a former President of the Royal College of Surgeons, Edinburgh, and of the Ophthalmological Society of the United Kingdom, has been invited to become prospective Unionist candidate, and he has agreed to place his services at the disposal of the constituency. Sir George, who was educated at Marlborough and Edinburgh University, and also studied in London, Paris, Copenhagen, Vienna, and Giessen, was from 1882 to 1905 ophthalmic surgeon to the Edinburgh Royal Infirmary, later he acted as one of the managers; and for the past ten years he has been a member of the University Court of the University of Edinburgh. During the war, and for one year after the war, he served as Chief of the Ophthalmic Department of the 2nd General Hospital, in which capacity he had sometimes to deal with 100 new cases a day. He was knighted in 1916 in recognition of his scientific work. Lady Berry is a daughter of the late Sir William Muir, K.C.S.I., for many years Vice-Chancellor and Principal of the University of Edinburgh.

EDINBURGH UNIVERSITY COURT.

At a meeting of the Edinburgh University Court, on June 13th, Professor Sir Robert Philip and Professor Ritchie were appointed representatives of the University to the International Conference on Tuberculosis to be held in London in July. The Court resolved, consequent on the approval of the ordinance concerning matriculation and graduation fees, that on and after September 1st, 1921, the matriculation fee payable at the beginning of each academic year should be two guineas instead of one guinea; the fees for the degrees of Bachelor of Medicine and Bachelor of Surgery are to be £34 13s., for the degree of Master of Surgery £21, and for the degree of Doctor of Medicine £21. As recorded in another column, the resignation was intimated, and received by the Court with great regret, of Professor Sir John Halliday Croom from the chair of midwifery, and the gift by the professor of all the preparations, specimens, apparatus, and diagrams collected during his tenure of the chair, was accepted with thanks. The Court accepted also the offer of the Associated Societies of the University to present the records of the Hunterian Medical Society, formerly one of the Associated Societies, but now defunct for many years, and directed that the records should be deposited in the University library. It was reported to the Court that Lord Lytton and other members of the Committee on Indian Students appointed by the India Office would visit Edinburgh University on Monday, June 27th, and successive days. The Court resolved to invite all the Indian students and graduates of the University resident in Edinburgh to meet the committee in the Old College on June 27th, at 4 p.m.

CARE OF THE BLIND.

The Scottish Board of Health has issued a circular to local authorities with regard to the Blind Persons Act, 1920, drawing attention to the desirability of making proper use of the existing facilities and of assisting voluntary effort. At present, it is pointed out, grants are payable to approved voluntary agencies in accordance with the regulations made by the Board in respect of such services

as workshops and homes; for the blind, hostels, home teaching, and book production. Application may, however, also be made by a voluntary agency for a grant in aid of any scheme of assistance other than those referred to in the regulations, which has for its object the betterment of the conditions of the blind or the prevention of blindness.

Ireland.

IRISH MEDICAL ASSOCIATION.

The annual general meeting of the Irish Medical Association was held in Dublin on June 15th, Dr. E. Magennis presiding. The statement of accounts showed a surplus of £851, and the membership at the end of the year was 631. The annual report and financial statement were adopted. Dr. Magennis was re-elected president, and in acknowledging the honour said that it had been suggested that the constitution of the Association should be altered, as the present system had not been a success; it was also proposed that the present subscription be increased. Dr. W. O'Sullivan was re-elected vice-president.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held in Dublin on June 15th at the Royal College of Physicians, with Sir James Craig in the chair. The annual report was read by Sir John Moore. The amount given in grants during the year was £1,201, and the revenue from all sources was £2,915. The President said that it was a serious reproach to the members of the medical profession that they did not realize the urgent need of supporting the Benevolent Fund Society.

ROYAL VICTORIA HOSPITAL, BELFAST.

At the meeting of the Board of Management of the Royal Victoria Hospital, Belfast, held on June 15th, S. B. Boyd Campbell, M.D., F.R.C.P. (Edin.), was appointed assistant physician, in the place of Dr. J. E. MacIlwaine, lately appointed physician.

Correspondence.

TREATMENT OF ACUTE TOXAEMIA.

SIR.—In his letter on this subject to the *JOURNAL* of June 4th Sir Archdall Reid states clearly a strong *prima facie* case for his belief that it is possible, by artificial means, to abstract toxin from sufferers under acute febrile diseases, and appeals to all ranks of the profession to make a trial of the treatment he has employed with a view to testing its value. Among the diseases mentioned by him as suitable for this trial are acute lobar pneumonia, diphtheria, measles, puerperal fever, sepsis, small-pox, etc., and the treatment he advocates is the giving, as early as possible, a dose of aspirin (10 grains), phenacetin (5 grains), and pulv. ipecac. co. (5 grains), to be repeated once or twice in twenty-four hours till the symptoms cease to recur. Unable as I am to make any such trial myself, but being sufficiently convinced of the importance of testing the results of Sir A. Reid's considerable experience in the matter, I ask for space for the following few remarks:

It seems essential (1) that the selected cases for testing should be in the earliest stage possible for observation, so as to lessen the likelihood of natural recovery at the recognized average periods; (2) that a careful diagnosis be made, and the symptoms, signs, and course of each case accurately recorded; (3) that every possible means be taken for careful examination of the sweat for the purpose of discovering the presence or absence of toxins.

Sir Archdall's hypothesis is based to some extent on the widespread belief that the sweating which occurs, whether in the so-called "critical" or continuous form, in many acute fevers is a natural method of cooling the healthy body; but this hypothesis also requires the assumption that elimination of toxins accompanies the sweating which so soon follows on the administration of each dose of the drug in febrile cases.

Lastly, though this point is perhaps not essential, I would remark that the exact nature of the drugs employed by Sir Archdall Reid may possibly escape the notice of

some who will make trial of this treatment. Some practitioners who object to phenacetin may prefer to give 15 grains of aspirin, and leave out the phenacetin; and some may question the importance of giving the compound ipecacuanha powder. Many may be inclined to attribute the rapid fall of temperature, abolition of headache, and sweating to the aspirin, and to give aspirin alone. I mention this as it seems desirable, in an extended trial of this great importance, that the medicine and doses used should be uniform throughout, and that, at least in the early trials for the purpose of testing the value of the treatment, Sir A. Reid's formula should be strictly followed. If the test corroborates his results, it would be of course open to anyone to modify the composition of the medicament employed.

There is an ample field for this testing in fever hospitals and especially in general practice.—I am, etc.,
London, W., June 19th. H. BRYAN DONKIN.

WHAT IS SCIENCE?

SIR,—In your issue of June 4th, in a very able and interesting leader on *Medicine a Science*, in which you do me the honour of mentioning my name, you have discussed various definitions of the word *science*. You quote specifically Sir William Osler's dictum that "the goal of science is the acquisition of new powers by new discoveries," and that of Clifford, recalled by Sir E. Ray Lankester: that "the subject of science is the human universe; that is to say, everything that is, or has been, or may be, related to man." You dismiss—rightly in my opinion—both these descriptions as not entirely satisfactory.

Now, I am far from being prepared to give a definition of science; still less am I in a position to correct or amend the definitions given by the very distinguished men whom you have quoted. Yet, without attempting to define science, may I suggest a provisional test for what is a science—a test that has been helpful to me, and, I think, may perhaps be of service to others? It is a test that I have ventured to apply tentatively in a chapter on "Science" contributed to a recent book on *Medieval Contributions to Modern Civilization*, edited by Professor F. J. C. Hearnshaw.

The test I apply is that *science is knowledge in the making*. We are all in danger of considering that science is a particular kind of knowledge, but reflection shows that it is not so. A Greek text, for example, may be scientifically treated and the scientist (called a philologist) may apply a perfectly scientific method in restoring or correcting it. Again, chemical knowledge can be quite unscientifically treated, as a glance at an advertisement of a quack remedy may rapidly convince us. The corrected text, however, can hardly be said to give "new powers" (to use Sir William Osler's phrase) in the ordinary sense of the word "power." Yet it is clearly knowledge in the making, and the text may be said to be scientifically edited.

Apply this test for a moment to medical studies, and let us take, as an example, the simplest and most fundamental of those studies. Descriptive human anatomy was, in the main, a creation of the sixteenth and seventeenth centuries. In the hands of Leonardo and Vesalius, of Fallopius, Fabricius ab Aquapendente and Eustachius, it was a progressive science. During the eighteenth and nineteenth centuries the limit of that type of knowledge was nearly reached. Descriptive anatomy is now a valuable and indispensable discipline, but it has almost as much ceased to be a science as has the equally indispensable knowledge of the multiplication table. Descriptive anatomy is hardly any longer knowledge in the making. Of course anatomists still retain their position as men of science—there are probably none with a better right to that title—but they do so mainly by virtue of the excursions they make into kindred and still progressive studies, such, for instance, as comparative anatomy, embryology, ethnology, physiological mechanics, and the like.

Apply the same test to the knowledge of a language. The grammar and construction of the classical and of the Western European languages are a fully explored field. The learning of them is a discipline; science has no part here. But there are still progressive sciences of phonetics and of comparative grammar. When the unwritten language of some wild tribe is from time to time explored, the process is or should be an application of scientific

method, and that method is still applicable to the imperfectly known languages of the monuments of the ancient East.

Science in this view is inextricably wrapped up with research; it is the growing edge between the unknown and the known, between the desert and the sown. In places this edge is sharp and clear, in places there is a wider and debatable area.

But there is a corollary arising out of this view of science as a process. To understand a process it is inevitably necessary to understand how it came to be what it is. A process is an organic thing—to understand it you must know and understand its history. Thus the teaching of science becomes, in its ultimate analysis, instruction in history; not, of course, what is usually termed "history" by the professed historians, nor even by the historians of science, but history, nevertheless. The "neuritic" method of teaching science—the only method that teaches science proper, the art of discovery, as distinct from the results of science—is in reality a method of recognizing this. You can only explain "scientific knowledge" by explaining *why* you hold that knowledge to be true knowledge. The answer to this question *Why?* must in its nature be a verification of past experience by present evidence, and this is, in fact, the method of history.

Thus we see the wheel turn full circle. The methods and the manner of teaching of the science of medicine that are so eloquently preached by Sir James Mackenzie are not far removed from the line of advance of what are too narrowly termed the "humanities." For the truth is that knowledge is one, and there is only one true and safe method of advancing it, and that is science. It is sometimes pathetic to see so-called "specialization" in scientific knowledge tending to separate men's thoughts and spheres of work rather than to unite them. This separation, however, mentally destructive though it be, can only be a passing phase, and is, perhaps, already declining. It is an evil against which the life work of the great men you have quoted—Osler and Clifford, Lankester and Mackenzie—stands out in lasting protest.—I am, etc.,

Oxford, June 15th.

CHARLES SINGER.

CAPILLARY PRESSURE.

SIR,—Dr. Gillespie (June 11th, p. 873) compares the capillaries to a soap bubble, and imagines the capillary wall as exerting a surface tension which raises the internal pressure. Now in the amputated leg of a frog the capillaries of the web of the foot are not emptied. Many remain full. It is evident, then, that the capillary wall does not exert a surface tension comparable to that of a soap bubble. The same thing holds good for the capillaries of the arm. Let the circulation be stopped by a tourniquet, after emptying the big veins by raising the arm for a second or two; the skin only slowly blanches, and the blanching that does take place seems to be brought about by gravity or bringing in the compressive action of the muscles. Again, in the case of the brain: when the skull is trephined and the dura incised the brain bulges in the trephine hole, but collapses when the heart stops beating and gravity comes into play. It does not collapse if the animal be so tilted that gravity keeps the vessels full. The surface tension energy imagined by Dr. Gillespie should certainly empty the capillaries against a very moderate opposing force of gravity.

If the brain ceases to bulge into the trephine hole when the heart stops beating, and the animal is in the horizontal position, it is just to infer that the expansion of the brain is due to that part of the force of the heart-beat which is left over after overcoming the resistance in the arteries and arterioles and maintaining the kinetic energy of flow, and the pressure that is required to reduce the bulging of the brain into the trephine hole is then the pressure that is required to overcome the expansion of the arteriole, capillary and venous network. That pressure is the same within the limits of measurement as the venous pressure measured directly in the torcular Herophili, and the same as that of the cerebro-spinal fluid measured by passing a hollow needle through the occipital atlantal membrane.

The method which I have used for measuring capillary pressure is one contrived by Roy and Graham Brown, and is one which has been used by many other physiologists. My findings are supported by Basle, who, after cutting

the finger and inserting it into a suitable vessel, measured the pressure to which the escaping blood raised the manometer—that is to say, he measured the internal pressure and found results which agree closely with those obtained by me using the Roy and Graham Brown apparatus.

In the amputated leg of the frog a very slight alteration of external pressure sends the corpuscles swirling along the capillary vessels. When the blood is flowing naturally a very small external pressure suffices to stop the flow in the outlying capillaries at the external edge of the web, the flow taking the pathway of less resistance through wider networks.

Physiological experiment has shown that an artery, big or small, when compressed by a surrounding fluid pressure, is shut up by a compressive force practically equal to that of the pressure which is maintaining the flow through the artery, and which is measured directly by a manometer connected with the lumen of the artery. The same holds good for a vein, big or small. It holds good also for the excised kidney when Ringer's fluid is circulated through it and the whole organ is submitted to external compression. It is known that a pressure of 10 to 15 mm. Hg suffices to maintain a circulation through the kidney. If the capillaries of the kidney were striving to contract like a soap bubble owing to surface tension, they ought to resist the flow of fluid at such low pressure.

The capillaries open into the veins, and measurement shows that venous pressure is very low, and in close agreement with the measurements of capillary pressure made by me. It seems highly improbable that there should be a high internal pressure produced by surface tension inside capillaries and a very low pressure in the veins with which they closely communicate. All these facts seem to show that we have the right to assume that the Roy and Graham Brown method holds good for the capillary sized vessel.

These statements are founded on physiological experiment, and if erroneous they can be overthrown by further experiment and more exact measurement. Physical theory unaccompanied by such experiment will do nothing to elucidate the principles of capillary circulation.—I am, etc.,

London, N.W. 3, June 14th.

LEONARD HILL.

Sir,—The application of even elementary facts in physics to physiological data presents more difficulty than is apparent at first sight. It is apt to be forgotten that the physicist, especially in his mathematical treatment of experimental data, simplifies his data as far as possible. He introduces into his argument certain postulates, but prefers not to have too many postulates to deal with. The physiologist, on the other hand, can advance only slowly because he can neglect no data whatsoever pertaining to his problem.

To illustrate: Dr. Gillespie, in his interesting letter, sees an analogy between the mechanism which maintains a soap-bubble wall under tension and the mechanism by means of which a capillary wall, though thin and flaccid, could withstand high capillary pressure. Now, in the case of a soap bubble the pressure distending it is created by the tendency of the walls—surface tension—to contract into smallest compass, and, as elementary books on physics state, the pressure inside a soap bubble decreases as the bubble gets larger. Consequently small radius of a capillary, it could pressure. After all, states Dr. Gillespie, the wall would be very small.

Now the physiologist may enter the field and ask whether the walls of a capillary actually behave like a soap-bubble film. If the pressure inside a soap bubble could be suddenly diminished below atmospheric the bubble walls would collapse. If, similarly, the pressure inside a capillary is reduced to zero we do not find that the walls of the capillary suddenly collapse. When the large veins are emptied by raising the arm for a few seconds and the brachial artery stopped by a tourniquet it takes quite a considerable time for the skin to become blanched, and even in this the blanching is aided by gravity. Evidently, then, there is no analogy between the tension of the wall of the soap bubble and the physical state of the wall of a capillary full of blood.

But I am quite willing to be aided by the simple formula used by Dr. Gillespie. I shall now proceed to apply it.

Let p_1 = pressure in the artery, for example, the artery in the capillary.

Let p_2 = pressure outside the artery, for example, pressure in the capillary.

Now, states Dr. Gillespie,

Let p_3 = the pressure caused by 50 mm. of Hg.

Here, again, the physiologist must interrupt the physicist. Where is that 50 mm. of Hg obtained? There is an airiness about that postulate of quite an engaging nature. The trouble is that no data whatever are available to the physiologist until he first measures p_1 plus p_2 , the pressure inside the capillary and the pressure outside the capillary.

Now the point arises whether the pressure outside the capillary can be compared with the pressure in a soap bubble. The skin is elastic and is distended by the imbibition of the tissues. Wounds we know gape. The skin then exerts a force inwardly. It, like the soap bubble film, struggles to contract itself into smaller compass. According to the latter part of Dr. Gillespie's argument, we shall not need so much pressure to blanch capillaries, because the skin is compressing them. Now we find that $p_1 + p_2$ may amount to 33 mm. of Hg, where the measurement is made at heart level on the skin of the last digit of the thumb.

But p_2 can be measured—that is, the pressure required to collapse the flaccid capillary wall—when we have reduced the capillary blood pressure to zero and then found the pressure required to blanch them. According to Dr. Gillespie, that should not require much pressure, for the distended capillary wall under tension is striving to collapse and the outside skin is striving to contract. A small pressure, much less than the internal tissue pressure, is sufficient, according to Dr. Gillespie, to narrow the capillary walls and squeeze the blood out. We find that the pressure required to blanch the same last digit of the thumb at heart level is 23 mm. of Hg.

Now $p_1 + p_2$ = 33 mm. of Hg.
 p_2 = 23 mm. of Hg.

Accordingly p_1 = 10 mm. of Hg.

and $p_1 - p_2$ = 10 mm. of Hg at proximal side.

following Dr. Gillespie,

$\frac{1}{r} = \frac{1}{12.5} \text{ cm.} \times \frac{1}{10 \text{ mm.}} \times \frac{1}{10 \text{ mm.}}$
 $\frac{1}{r} = \frac{1}{12.5} \text{ cm.} \times \frac{1}{10 \text{ mm.}} \times \frac{1}{10 \text{ mm.}}$

Then $\frac{1}{r} = \frac{1}{12.5} \text{ cm.} \times \frac{1}{10 \text{ mm.}} \times \frac{1}{10 \text{ mm.}}$
and $T = 0.00005 \text{ gram per cm. of length.}$

It will be noted that when physiology enters the field and supplies actual measurements in place of a gross assumption of 50 mm. of Hg, as the value of $p_1 - p_2$, Dr. Gillespie's application of simple physical law shows the tension per unit of length tending to split the tube longitudinally is actually a minus quantity. Is not this the result to be expected? No such tension exists.

The fact is, Dr. Hill is as nearly correct as any man of equal eminence who has devoted a large measure of his life to the study of these difficult problems can hope to be in the present state of our knowledge. The capillary wall is, to use Dr. Gillespie's phrase, "so thin and collapsible"; the venous wall is thicker but collapsible. The moment you compress and diminish the calibre of a vein by outside pressure, you measure the internal pressure. Similarly in a capillary, but with this fundamental physiological difficulty before you, in both cases—if you constrict the wall even slightly, the pressure you measure is no longer capillary but mounts automatically to the higher arteriole pressure of the entering blood stream.

There is no evidence whatever that the capillary wall is under strain like the film of a soap bubble. If you block by compression a capillary by stopping a red corpuscle, you have overtopped the internal capillary pressure without any assistance whatever from the flaccid capillary wall.

Finally, in the case of the measurement of arterial blood pressure it has been found that stoppage of the pulse wave accurately measures the systolic pressure and gives practically the same reading as a manometer connected directly with the artery. The blood flow stops at a pressure of at most a few millimetres of Hg higher.

Now the arterial wall is under distension, and to this extent may be compared to a soap-bubble film. It exerts

pressure tending to narrow the artery. But we have to exert a pressure equal to the internal pressure and no less to stop the pulse wave when the armlet is used on the upper arm.—I am, etc.,

Halesowen, June 10th.

JAMES M. McQUEEN.

HEART-BLOCK.

SIR,—In your issue of June 11th Dr. G. Arbour Stephens makes some criticisms on my paper on heart-block which appeared in the *JOURNAL* of June 4th. Especially he calls in question my justification for the statement "it is clear that the systolic plateau is dimpled by the drag of the contracting auricle," and in connexion with this he asks "Is it the function of the auricle to 'dimple,' and if not, why in this particular case?"

I think it is generally recognized that when the auricle contracts at its usual time, that is to say, immediately before the ventricle, it will drive blood into that cavity, and cause the apex to rise against the chest wall to such an extent that in many cases, though not in all, this may be demonstrated in a tracing taken from the apex beat. It has been explained to us, and by no one better than by Sir Arthur Keith, that the auricles not only drive blood into the ventricles, but pull the bases of the ventricles upwards and backwards over the volume of blood in the auricles, and he happily likens this double action to that of a man pulling on a boot; for not only does he push his foot into the boot, but he pulls the boot up over his foot. Now, when the left auricle contracts, as it normally does at a time when the ventricle is at rest, its pull at the base in a direction away from the apex of the heart is more than neutralized in many instances by the projection of blood into the cavity of the ventricle, whose apex therefore is caused to rise, as may be shown in a tracing. When, however, the auricle contracts at the same time as the ventricle, there is probably no passage of blood into the lower chamber, and there will be no such wave as I have described. On the other hand, the auricle will, by its contraction, draw back the base of the ventricle in the manner described by Keith, and this will result in a dimpling of the systolic plateau.

It may be asked, "If the auricle cannot drive its blood onwards when it contracts at the same time as the ventricle, what becomes of that blood?" I suppose the answer to this is that it is driven back to some extent into the pulmonary veins, in the same way as we know from jugular tracings that the right auricle drives blood back into the veins of the neck when it finds itself contracting at the same time as the ventricle in some varieties of extrasystole, and in certain cases of spasmodic tachycardia. It is only therefore, I repeat, when the auricle and ventricle are contracting synchronously, and especially when the auricular systole falls near the middle of that of the ventricle, that we should expect to find this dimpling. It is seen in Figs. 4 and 5 of my paper that every fourth ventricular systole, and only every fourth, has an auricular systole associated with it in this manner. It is the plateaus of those systoles, and of those alone, therefore, which show the dimpling. The observation is not an original one on my part.

I am well aware how deceptive tracings taken from the region of the apex may be. As Mackenzie pointed out long ago, a systolic plateau may easily be represented by a systolic depression if care is not taken to place the receiver exactly over the apex beat. There may be no accessible apex beat, and that which has been so regarded may have its real character exposed by presenting a depression which is found to be systolic in time. During the systole of the ventricle there is often some lateral movement of the apex, and so the "apex tracing" may present mixed characters, and the movements of respiration may cause the tracing to present a rhythmical transition from plateaus to depressions. Now before I accept a tracing as being that of the apex beat, I try to eliminate these and other sources of fallacy. My receiver is $1\frac{1}{2}$ inch in diameter, and it might I think with advantage be less; a receiver three inches in diameter cannot give a tracing of the "apex beat" alone with accuracy, for this is a phenomenon limited to the apex of the heart. It may be the case that valuable information can be obtained by the use of a receiver of this size, but it would be the resultant of more than one movement and not the effect merely of the forward thrust, of the maintenance of this and of the

recession, and it was these alone with which I was concerned.

Dr. Stephens says I have given "no consideration . . . to the quantity and quality of the pericardial fluid present." That is true; but in none of the cases was there any evidence of fluid in the pericardial cavity. The absence of the ordinary signs of pericardial effusion is, of course, quite compatible with the presence in the sac of a considerable increase in the amount of the physiological secretion. My attention has not been directed to the influence of such small quantities of fluid on the characters of the apex beat.

Dr. Stephens claims more for my tracing (Fig. 5), and sees more in it than I do myself. To me, apart from the points discussed, it shows merely a condition of complete heart-block, and tells me nothing as to its causation; to Dr. Stephens it "suggests a toxic condition." The subsequent history does, I agree, lend support to such a view, with which, however, I was not concerned in my paper, but I cannot read into the tracing anything bearing upon the cause of the block.

I am quoted as having stated that my first case (the italics are my own) died "without any obvious (sic) cardiac symptoms." If I am right in supposing that the "sic" implies an incorrect use by me of the word "obvious" I do not agree. But the criticism may be on other grounds; and I may be in the position of Diogenes Teufelsdröckh, who was asked to believe that the reason for the appalling epitaph he had written not being engraved was a "defect of Latinity." I do regret, however, that Dr. Stephens has, quite accidentally, I feel sure, quoted me as saying "the case died." I am glad to feel that I did not express myself in those words. What I wrote was "He"—that is to say the patient—"died."—I am, etc.,

Leeds, June 20th.

T. WARDROP GRIFFITH.

VOLUNTARY HOSPITALS COMMITTEE.

SIR,—In Section 39, with reference to the "contributors' certificates" issued at the Great Northern Central Hospital, the Committee says: "The scheme is in its infancy, and we are unable to express an opinion as to its value." The Committee must here be speaking of "value" in a financial sense only, since the contributor's certificate is merely the old "subscriber's line," which, from the medical standpoint, experience has shown to be an unmitigated evil. It is evil in two aspects. For many years, and as recently as this month, I have heard hospital officers allege that it is difficult to keep beds clear for cases medically urgent because cases not medically urgent are admitted in virtue of holding a line from a subscriber whom it will not do to offend. Thus, in practice, a non-medical condition takes precedence of medical urgency in the admission of patients. In the second place, I have known of the relatives of poor people sacrificing a whole working day in the search for a line which had been demanded after the patient was admitted. This was a means of impressing on them the importance of the hospital subscription in a factory or in a congregation.

No matter how generously the "voluntary" regulations are drawn, in practice constant supervision is needed to guard against an insidious entry of compulsion.—I am, etc.,

Dundee, June 19th.

R. C. BRIST.

CAMBRIDGE DIPLOMA IN HYGIENE.

SIR,—The University of Cambridge, in response to a communication from the League of Red Cross Societies at Geneva, has established a new Diploma in Hygiene.

In order that the scheme may assume an international aspect, it is hoped to bring together men representing the views of different countries; and that candidates from advanced countries, such as America and Scandinavia, as well as those from the more recently reorganized nations of Eastern Europe, may avail themselves of the facilities provided in these classes.

The training is primarily intended to benefit those who wish to familiarize themselves with English methods of sanitary science and practice, and to return to their own countries holding an official certificate that they are qualified to act as officers of health.

The diploma is open to candidates from all countries outside the British Dominions who possess a qualification to practise medicine or surgery which, though not registrable in Great Britain, is recognized by the authority of

the country in which the candidate practises. The diploma is not registrable by the General Medical Council of Great Britain and Ireland.

The full course must extend over a period of nine calendar months, and all candidates must have matriculated and resided in the University for not less than two terms, or for one term and during a long vacation course. The examination is divided into two parts, and the requirements for each part are similar to those demanded for the diploma in public health, with the exception that no detailed knowledge of English public health laws and statutes will be called for. It appears to be more important that candidates should become acquainted with the general principles of the English code of sanitary legislation than that they should possess a detailed knowledge of the legal duties and responsibilities of our sanitary authorities.

Arrangements are now being completed to ensure lodging accommodation not only for D.P.H. students but for the students who intend to take the diploma in hygiene.—I am, etc.,

J. E. PRINIS,

Secretary to the State Medicine Syndicate.

Public Health Laboratory, Cambridge,
June 15th.

COCCYGEAL FISTULAE.

SIR.—I have read Mr. Ernest Miles's comments on my paper on coccygeal fistulae in your issue of June 18th with much interest. There are one or two points which seem to me to call for a reply.

I did not mean to convey that all abscesses and fistulae over the coccyx are necessarily due to dermoids. Ordinary abscesses may, of course, occur in this as in any other situation due to caries of underlying bone, etc.; but the majority of such lesions in this situation will, I believe, prove to be due to the causes I have described.

The condition described by the late Mr. Goodsall as "sinuses over the sacrum and coccyx" is, I feel sure, the same as that which I have described as congenital coccygeal fistulae, in spite of Mr. Miles's arguments to the contrary. As no sections were made in Mr. Goodsall's cases it is not possible to prove this, but the descriptions given of his 10 cases bear such similarity to my own that I feel sure had a microscopical examination of sections of the fistulous tracks been made their congenital origin would have been apparent.

Mr. Miles seems to attach much importance to the opening of these sinuses being in the middle line, and to argue that when the opening is not in the middle line the sinuses cannot be congenital in origin. These congenital sinuses, however, may open in any direction, as the external openings are more often than not due to the secondary septic infection. Only this week I operated upon a patient in whom there was a large fistula with two long tracks running forward, one on each side of the anus, and opening on each side in front of the anus. Posteriorly these tracks communicated with a small cavity over the tip of the coccyx. This cavity proved to be a dermoid cyst of congenital origin, which had suppurated as the result of injury.

Most of the reasons given by Mr. Miles for considering that these sinuses are not congenital are quite unconvincing. Unless a case is seen before there is any sinus, it is not possible to know whether there had previously been a dimple or not. There may be quite a large amount of granulation tissue where suppuration has been going on for some time, and I see no reason why the aperture should not temporarily close, even where the sinus is congenital in origin, since it does not follow that the external opening, which is usually the result of secondary suppuration, is lined with skin. Teeth one would not expect to find in an inclusion dermoid.

With regard to their not being lined with skin, this can only be ascertained by a microscopical examination, as considerable modification of the lining membrane may have taken place as the result of suppuration. These cases are not so rare as Mr. Miles thinks. Since I have been on the look-out for them I have seen quite a number, and I feel sure that if Mr. Miles will have sections cut of such cases, he will be surprised by the number in which he finds evidence of congenital origin, in spite of the history

of injury, and the fact that there had been no previous history of any lump.—I am, etc.,

J. P. LOCKHART-MURCHLEY, F.R.C.S.

London, June 14th.

NORTH EUROPEAN CONFERENCE ON VENEREAL DISEASES.

SIR.—In reference to your report of this conference, appearing in the JOURNAL of June 18th, permit me to inform you that the English delegates to the conference consisted of: Colonel L. W. Harrison, Dr. F. N. Kay Menzies, and Mrs. C. Neville Rolfe (Mrs. Gottol), who are well known opponents to immediate self-disinfection as a method of prevention.

Directly I heard that the conference had been arranged, I communicated with the Danish Red Cross at Copenhagen, requesting that my society should be represented at the conference, and the secretary sent me a most courteous reply, intimating that he would be pleased to welcome delegates from the Society for the Prevention of Venereal Disease, but that the selection of such delegates was entirely in the hands of the British Red Cross. I thereupon reiterated my request to the British Red Cross, and received a reply stating that the Society for the Prevention of Venereal Disease could not be represented at the conference, as the League of Red Cross Societies at Geneva had adopted the National Council for Combating Venereal Diseases as the recognized channel in this country, for communications on these subjects, and that they had already selected the delegates mentioned above.

The views of that very large section of the public in this country, who support the policy of immediate self-disinfection advocated by the Society for the Prevention of Venereal Disease, had no opportunity, therefore, of being represented at the conference, and this important aspect of venereal disease prevention was therefore largely neglected.—I am, etc.,

H. WATNEY BAILY,
Hon. Sec. S.P.V.D.

London, W., June 17th.

THE PATHOLOGICAL MUSEUM AT THE ANNUAL MEETING.

SIR.—The Committee wish to call attention to the importance of the Pathological Museum, and the necessity of making it an adjunct to the work of the Sections.

It is requested that readers of papers in the various Sections, or others taking part in the discussions, should have specimens illustrating these to show, and should communicate at once with the Secretary of the Pathological Museum Committee. This also applies to anyone who wishes to exhibit specimens of general interest.—I am, etc.,

A. F. BRIDGES SAW, M.D.,

Honorary Secretary, Pathological Museum,
College of Medicine, Newcastle upon Tyne,
June 16th.

The Services.

INDIAN MEDICAL SERVICE.

ANNUAL DINNER IN LONDON.

The annual dinner in London of the Indian Medical Service took place on the evening of June 15th, when Major-General Sir R. Havelock Charles, G.C.V.O., M.D., Medical Adviser to the Secretary of State for India, was in the chair.

The officers present were:

Major-Generals: E. E. Giffard, C.S.I., G. F. A. Harris, C.S.I., Sir P. Hehir, K.C.I.E., C.B., C.M.G.
Colonels: J. K. Chose, J. Crimmin, V.C., C.B., C.I.E., Sir P. J. Freyer, K.C.B., J. J. Pratt, H. Austen Smith, C.I.E., C. N. C. Wimberley, C.M.G.

Lieutenant-Colonels: A. Alcock, C.I.E., W. G. P. Alpin, O.B.E., J. Anderson, C.I.E., F. V. O. Beit, G. T. Birdwood, L. P. Brassey, A. W. T. Buist, W. H. Burke, S. H. Burnett, D. G. Crawford, C. D. Daves, R. H. Elliot, S. C. Evans, A. A. Gibbs, L. Hirsch, C.I.E., C. T. Hudson, C.M.G., E. V. Hugo, C.M.G., J. G. Hulbert, C. P. James, J. G. Jordan, H. Kirkpatrick, W. Glen Lister, C.I.E., R. McCarrison, R. H. J. Meyer, A. Miller, R. A. Needham, C.I.E., D.S.O., J. W. F. Rait, Sir J. Rogers, C.I.E., A. Spitteler, R. Steen, W. A. Sykes, D.S.O., W. H. Thornhill, W. Vost, J. N. Walker, H. J. Walton, J. H. Tull Walsh, H. R. Woolbert, J. C. S. Vaughan, A. C. Younan, A. W. Cook Young.

Majors: H. C. Brown, C.I.E., H. P. Cook, W. T. Finlayson, D.S.O., C. A. Goldson, M.C., I. Davenport Jones, H. C. Keates, W. D. Keyworth, H. H. King, A. A. McNeill, M. J. Quirke,

F. B. Shettle, E. C. Taylor, C. Thomson, W. P. G. Williams, N. M. Wilson, W. E. Rees Williams, O.B.E.
Captains: P. M. Antia, H. S. Cormack, M. L. C. Irvine, N. N. G. C. McVean, N. D. Pari.

The guests were the Editors of the BRITISH MEDICAL JOURNAL and the *Lancet*.

The toast to the Service was given by the Chairman; Colonel R. H. Elliot, who proposed the health of Sir Harelock Charles, eulogized his loyal defence of the interests of the Service. The toast was very warmly received and suitably acknowledged.

ROYAL NAVAL MEDICAL SERVICE.

APPROVAL has been given this year by His Majesty in Council for the following alterations in the regulations regarding promotion. They are applicable to medical officers of the Royal Naval Reserve and Royal Naval Volunteer Reserve serving on July 1st, 1919:

(a) Surgeon Lieutenants to be eligible for promotion after six years instead of eight as at present, the promotion of those on the list on July 1st, 1919, being antedated as necessary.

(b) Surgeon Lieutenant Commanders to be eligible for promotion to Surgeon Commander after six years instead of eight as at present, those on the list on July 1st, 1919, being given two years' seniority.

(c) Surgeon Commanders on the list on July 1st, 1919, to be given two years' seniority.

(d) The necessary promotions to the ranks of Surgeon-Lieutenant Commander and Surgeon Commander to be made.

(e) The period of sea service required to qualify an officer for promotion to the ranks of Surgeon Lieutenant Commander and Surgeon Commander to be reduced from three to two years.

Officers who are promoted, or whose seniority is antedated under any of these rules, will not receive any advantage in respect thereof as regards pay from a date earlier than July 1st, 1919, but they will be granted such increments of pay as their new rank or seniority may entitle them to as from that date.

NAVAL, MILITARY, AND AIR FORCE HYGIENE.

A MEETING of the Naval, Military, and Air Force Hygiene Group of the Society of Medical Officers of Health will be held at the house of the Society, 1, Upper Montague Street, W.C., on Thursday, June 30th, at 4.30 p.m. Colonel H. W. Grattan, C.B.E., D.S.O., A.M.S., Deputy Director of Hygiene, War Office, will read a paper on "The co-operation between civil and military sanitary authorities during a grave national emergency."

HONOURS.

THE following appointments to the Order of the British Empire are announced:

To be Officers (Military Division).—Major (acting Lieut.-Colonel) John B. Dalzell-Hunter and Captain (acting Lieut.-Colonel) James Bennett Hance, of the Indian Medical Services, awarded in connexion with m. within t William of value against

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on June 16th the degree of Doctor of Medicine was conferred on Herbert C. Squires.

UNIVERSITY OF CAMBRIDGE.

DR. G. H. F. NUTTALL's reappointment for three years as Quick Professor of Biology expires in November, 1921, and a fresh election to the chair will be held on July 20th.

Dr. Louis Cobbett has been reappointed University Lecturer in Pathology.

At the congregation held on June 10th the degree of Doctor of Medicine was conferred on Mark Avent (Gonville and Caius College).

UNIVERSITY OF LONDON.

Semon Lecture, 1920-21.

DR. W. JOHNSON HORNE, President of the Laryngological Section of the Royal Society of Medicine, will deliver the Semon lecture in the lecture hall of the Royal Society of Medicine, 1, Wimpole Street, W.1, on Tuesday, July 5th, at 5 p.m. The chair will be taken by Mr. Herbert Tilley, F.R.C.S. The subject of the lecture is "The relationship of the larynx to pulmonary tuberculosis" (with lantern illustrations).

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary comitia of the Royal College of Physicians of London was held on June 15th, the President, Sir Norman Moore, Bt., occupying the chair. Communications were received (1) from the Secretary of the Royal College of Surgeons:

these were read and entered on the minutes; (2) from Jugalkisor Adhya, M.B., M.R.C.P., resigning the Membership of the College; this was accepted. Sir Humphry D. Rolleston was appointed a representative of the College on the Court of Governors of the University of Sheffield in place of Dr. T. D. Acland. A report from the representative of the College on the General Medical Council concerning the meeting of the Council held in May last was received and ordered to be entered in the minutes.

After some discussion the following resolution was passed and referred to the Committee of Management for report to the College:

That every candidate for the conjoint diploma of the Royal College of Physicians and the Royal College of Surgeons shall be required to produce evidence of adequate training in diseases of children, and that the final examination shall include examination in diseases of children.

The President then dissolved the comitia.

Obituary.

CHARLES JAMES MORTON, M.D., C.M.EDIN.

DR. CHARLES JAMES MORTON, who died at Territet, Switzerland, on May 28th, at the age of 57 years, received his medical education at Edinburgh, taking the degree of M.B., C.M., and the diplomas L.R.C.P., L.R.C.S.EDIN., and L.R.F.P.S.Glasg. in 1886. After some time spent in study in London and Vienna, he took his M.D. degree in 1890, and in the same year settled at Walthamstow, where he practised for fifteen years and was much beloved by patients of all classes. He took great interest in the work of the British Medical Association, was secretary of the East London and Essex District of the Metropolitan Counties Branch in 1900-1, secretary of the Walthamstow Division during 1903-5, and Representative of the Walthamstow Division in the Representative Body for 1904-7. After leaving Walthamstow he migrated to Welbeck Street, where he practised as a radiologist. He was appointed radiologist at Guy's Hospital in 1907, doing much good work there till 1912, when failing health compelled him to resign.

On the outbreak of war Dr. Morton immediately offered his services, and received his commission in the Royal Army Medical Corps in 1914, being posted as radiologist to the Pavilion (Indian) Hospital, Brighton, and afterwards in a similar capacity to the Kitchener and 2nd Eastern Hospitals. He served until March, 1920, but his health having suffered severely from the labours of these strenuous years, he was obliged to give up active work and retire to Switzerland.

In addition to other offices Dr. Morton was consulting physician to the Walthamstow Dispensary and consulting radiologist to the Surrey County Hospital. Though not a prolific writer, he contributed a number of very practical articles on radiology to medical periodicals. His loss will be felt by a wide circle of friends, especially those of his profession whose interests he always had at heart. He leaves behind a widow and daughter.

Medical News.

IT has not been found possible to arrange for a meeting in July of the Dermatological Section of the Royal Society of Medicine.

MR. A. M. M. FORBES, coroner for East Middlesex, has been elected President of the Coroners' Society for England and Wales.

THE sixth annual meeting of the National Council for Combating Venereal Diseases will be held at the Morley Hall, George Street, Hanover Square, W., on Tuesday, June 28th, at 4.15 p.m., when Lord Gorell will preside.

DR. R. M. F. PICKEN, Assistant Medical Officer of Health, Glasgow, has been appointed Medical Officer of Health of the City of Cardiff and Port Sanitary Officer.

A CONFERENCE under the joint auspices of the Central Committee for the Care of Cripples, 19, Berkeley Street, London, W.1, and the Newcastle Invalid Children's Aid Association, 17, Ellison Place, Newcastle upon Tyne, will be held at Newcastle on July 19th, 1921. The subjects for discussion will be the treatment and education of physically defective children and the best methods of administration and co-ordination to procure the same. Programmes will be ready by the first week in July.

... Tax is chargeable under Schedule D "in respect of the annual profits or gains arising or accruing to any person residing in the United Kingdom from any trade, profession ... whether the same be respectively carried on in the

United Kingdom or elsewhere." If our correspondent maintains a residence in this country and actually resides here personally during a portion of any financial year, we anticipate that he would be held liable on the whole of the net profits; if he was not in this country during the year we consider he could claim exemption on his foreign earnings. The question is not one of domicile, but of residence. "Domicile," as our correspondent is no doubt aware, has a technical legal meaning. A man might give up his residence here and with his family reside wholly abroad, while still retaining his English domicile.

"NESTOR" has for fifteen years returned and been assessed on the basis of three years' average receipts, "less expenses for the year in question." He is now asked to have his books audited and to supply a copy of the resulting profit and loss account.

"We advise 'Nestor' to point out that he has made his return on a cash basis for fifteen years, and that that method is established as the appropriate method of dealing with medical profits over the whole country. It has to be borne in mind that this system, however, breaks down when any special cause enters to increase or decrease the receipts; as, for instance, in the case of the purchase of an additional practice or the sale of a panel connexion, but we assume that there has been no such cause in this case. Our correspondent, however, is not quite correct on the question of expenses; these, like the receipts, should be taken on the basis of the three years.

"H." had to buy a second car in 1920 owing to the fact that his first car had broken down and was necessarily out of commission for some time. The car was bought for £350 and sold for £100 when the first car became available.

"* On the facts stated, and assuming that the two cars were not used together for any appreciable period, we are of opinion that the loss of £250 on the purchase and resale of the second car can properly be treated as an expense incurred in the overhaul of the first car.

LETTERS, NOTES, ETC.

DENTAL CARIES, APPENDICITIS, AND GASTRIC ULCER.

DR. W. E. NICKOLLS DUNN (London, W.) writes: In his letter from Mauritius in the JOURNAL of June 4th Dr. Andrew Balfour comments on the prevalence of ankylostomiasis. He continues, "Other worm infections are exceedingly common, and so, be it noted, is appendicitis." For several years I was in charge of the Luxor Hospital for natives in Upper Egypt, and much to my surprise I never saw ankylostomiasis was almost universal many years I have pointed out that my patients had for the most part sound teeth, and that I never saw appendicitis, gastric ulcer, or cancer of breast or stomach. The town arab acquires dental caries, and the Egyptian surgeons inform me that they see appendicitis amongst the arab children in Cairo. In my opinion our diet, which causes dental caries, may also cause the appendicitis, ulcer, and cancer of the stomach. It is my expectation that with prevention of dental caries the above-named diseases will become infrequent.

NEED FOR POST-GRADUATE INSTRUCTION IN MOUTH SEPSIS.

"X. Y. Z." writes with reference to the difficulty "A. B. C."—a dental surgeon—is experiencing in arranging demonstrations, as part of a post-graduate course, at the hospital to which he is attached: In my opinion, no post-graduate course in medicine is complete without this subject being fully dealt with; indeed, so strongly do I feel about it that I would go farther and say that if time is a factor to be considered, then some of the less important classes should be cut out in order to give this subject a proper opportunity of being taught. The holding of such an opinion seems all the more justified after reading the article "The coming of age of oral sepsis," by Dr. William Hunter, which appears in the JOURNAL of June 11th, p. 859.

THE CHEMISTS' EXHIBITION.

THE Chemists' Exhibition, the twenty-second in a series organized by the British and Colonial Pharmacists, was held during five days of this week at the Central Hall, Westminster. The exhibits were confined to medicinal, dietary, and toilet preparations, but even with this restriction the contributions of nearly a hundred firms crowded two large floors. The general appearance of the stands said much, not only for skill and ingenuity in chemical manufacture, but for that decorative ability which makes the most of the product. The pharmaceutical craft is very old, receptive though it be of modern notions, and one firm (Allen and Hanbury, Ltd.), amid a tempting display of their gelatine capsules and other goods, summoned up some ghosts of former times by exhibiting their old prescription books and ledgers, dating

back to the eighteenth century, from which many quaint extracts might be made. Another old firm, with considerably more than a century behind it—Howards and Sons, Ltd.—made a feature of their standard ether and quinine salts and aspirin tablets; and then again, to show the stability of British firms, there was Pears' soap, which began its career in the reign of George III. Many exhibitors emphasized the wide range of their products, while others concentrated on a single article. Among the former were Parke, Davis and Co., with their lozenges and pills and soaps and peroxide solutions, making a very effective display, Genatosan, Limited, the British purchasers of the Sanatogen Company, and the Hoffmann-La Roche Works, from which came alkaloids, fine chemicals and pharmaceutical products. On the other hand, one large stall—that of William Browning Co., Ltd., a pioneer firm along this line—was devoted to purified petroleum and petroleum jellies. British Colloids, Ltd., placed in the forefront two of their colloidal preparations—one of metallic silver, and the other containing iron in colloidal form. Then there were on view such well known preparations as Glaxo products, Horlick's malted milk, and, on another range of application, were soaps and ointments at the stand of Newbery and Sons, Ltd., the Sanitas fluids and powders and embrocations, and the Milton disinfectant, a clear hypochlorite fluid. A little aside from the strict purpose of the exhibition, but none the less interesting, was a display of supports, pads, and cushions for the feet, shown by the Scholl Manufacturing Co., Ltd., and a range of natural mineral waters, brought together by Ingram and Royle, Ltd., the product of half a hundred springs, from Aix-les-Bains to Woodhall Spa. Elsewhere in the exhibition one noted many improvements in the way of syringes, atomizers, tubes, sprinklers, bottle-caps, and the like. The ingenuity shown in this direction seems to make an advance with each successive exhibition.

POST AND PROPTER.

"T. L. B." writes: A town medical society, taking its annual half holiday this week at a remote moorland village, where the only resident doctor had died a short time previously, was confronted by the following typewritten notice in the church signed by the two chairmen of parish meetings:

"A public meeting of the inhabitants of B— and H— will be held in the school at B— on Saturday, April 30th, 1921, at 7 p.m., to discuss the possibility of securing the services of a doctor for the district; and to consider the question of providing a hearse for the two parishes."

This apparent slur on the profession caused, at first, some consternation, but serene feelings were restored when it was recognized that the villagers had apparently never felt the need of a hearse until they were without a doctor.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 32 and 33.

THE appointments of certifying factory surgeon at Ruabon (Denbigh) and West Drayton (Middlesex) are vacant.

THE post of one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Falmouth and Truro, Helston, Newquay, Penzance, Redruth, and St. Austell County Courts, in Circuit No. 59, is vacant. Applications to the Private Secretary, Home Office, by July 13th.

Cultivation of Medicinal Plants in Scotland, by R. Glode Guyer, is the title of a little book which has been published at the price of 1s. 6d. by the well-known drug firm of Duncan, Flockhart and Co., Edinburgh and London. An interesting account of the romantic early history of the cultivation of medicinal plants in Scotland introduces the story, illustrated by photographs, of the establishment in 1915 by Messrs. Duncan and Flockhart of gardens at Edinburgh for the cultivation of medicinal plants under their laboratory control.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	19 0 0
Whole page	27 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-
rested letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

716. Reduction of Nervous Irritability.

JACOBSON (*Journ. Nerv. and Ment. Dis.*, April, 1921) urges the importance of the principle of progressive relaxation in the reduction of nervous irritability and excitement, or nervousness. Since overactivity or increased tonus of the central nervous system, as shown in tenseness or excessive movement of striated muscles, is under voluntary control it is sought to cultivate such control in order to counteract excessive activity, thereby quietening the nervous system. Experience shows that when the patient learns how to relax the voluntary system a similar quiescence follows in the autonomic apparatus, the emotions tending to subside as he relaxes. The method consists of voluntary continued reduction of contraction or tonus of muscle groups, the relaxation being progressive in each group and consecutively with other groups, so that the patient tends towards a state in which quiet is automatically maintained. When an unpractised person lies as quietly as possible on a couch there still remains some residual tension, or voluntary fine contraction, which has further to be overcome for successful results. The practised person aims at noting the location of tenseness and doing away with it, yet attention must not be concentrated on his muscles, as all effort, even the effort to relax, has to be avoided. In simple form the patient is directed to relax whatever parts appear to be tense, or a few representative muscle groups may be selected for practice on the assumption that progressive relaxation of one part tends to be followed by a similar condition in other parts. Treatments vary in duration and number according to the case, averaging about thirty minutes, repeated weekly or bi-weekly.

720. The Rate of Propagation of the Arterial Pulse Wave.

LAUREY, MOUGLOR, and GIRONX (*Arch. de mal. du coeur*, February and March, 1921), as the result of their investigations on the rate of propagation of the arterial pulse wave in health and disease, come to the following conclusions: (1) The rate of propagation of the arterial pulse wave in physiological conditions is about 6 metres a second in the upper limb and 9 metres in the lower limb. (2) In all cases in which the rate was determined in the lower limb below Scarp's triangle, it was distinctly less than in the upper limb. (3) Under pathological conditions the rate of propagation of the arterial wave varies in relation with the blood pressure, and the changes in the rate are related to the variations in the systolic pressure. (4) When the relation between the rate of the arterial pulse wave and the systolic tension is destroyed, signs of cardiac failure are almost always present. In other words, slowing of the pulse should, *ceteris paribus*, be regarded as a sign of insufficiency of the left ventricle. (5) Loss of arterial elasticity produces such definite changes in the rate that a radio-femoral asynchronism results, the femoral being in advance of the radial pulse—an important sign in the diagnosis of thoracic or abdominal aortitis. (6) Sudden and localized changes in the calibre of the artery, as in pure aortic stenosis or aneurysm, has a distinctly retarding influence upon the rate. (7) The relations of the rate of the arterial pulse wave with the vascular tone were studied in disordered action of the heart, especially in Graves's disease, with inconstant results, the rate being normal in some cases and accelerated in others. (8) Determination of the rate of propagation of the arterial pulse wave is capable of giving valuable information, especially as regards vascular sclerosis, localized sclerosis of the aorta, and insufficiency of the left ventricle.

721. Digitalis in the Treatment of Hypertension.

ACCORDING to DAMADE (*Gaz. hebdomadaire de la Méd. de Bordeaux*, April 10th, 1921) until recently most clinicians were opposed to the use of digitalis in arterio-sclerosis or cardio-renal disease, at least before the stage of complete cardiac failure. The work of Vaguez and Lian, however, in 1913, on insufficiency of the left ventricle, of Martinet in 1914 on the laws of the circulation and diuresis, and of Josué and Godlewski in 1912 and of Gallavardin in 1920 on the use of digitalis, showed that this drug was also indicated in hypertension associated with failing compensation. Damade, who records four

personal cases, recommends that large doses should never be used, 10 drops of digitaline, repeated for four or five days, and in some cases half this dose, being sufficient. The treatment should be controlled by a daily study of the blood pressure. Any rise of the minimal blood pressure should be an indication to discontinue the treatment or to diminish the doses. The success of the treatment is an important factor in the prognosis. Damade having always found that failure to respond to digitalis is a bad sign.

722. Zinc Chloride Poisoning.

MCCOY and KILMER (*Journ. Am. Med. Assoc.*, February 12th, 1921) report an outbreak of dermatitis from zinc chloride poisoning among workers in a wood-preserving industry. In addition to the dermatitis and as a due to tar, multiple lesions of the fingers, hands, and forearm were noted following upon some slight injury such as abrasions, splinters, burns, or chapping. The typical lesion was a small opening in the skin corresponding in size to the antecedent injury, but on examination the surrounding skin was readily removable, revealing white and bloodless, underlying tissues, in the centre of which was a cylinder of escharotic tissue. When this was removed and the crater filled with sodium bicarbonate healing took place. The lesions occurred among workers with railway ties which had been subjected to treatment with zinc chloride solution, which after exposure to air approached saturation. Prevention for the hands was secured by the use of flexible "indented" canvas gauntlets, which were found to be impervious to the fluid and were comfortable, durable, and inexpensive, and by prompt treatment of all trivial injuries of the hands and forearms.

723. Acute Nitrobenzol Poisoning.

LOHN, BOKE, and FITZ (*Am. Journ. Med. Sciences*, April, 1921) find that the oxygen capacity of the blood in cases of nitrobenzol poisoning is markedly diminished, in one case as low as 6.2 volumes per cent., while the total amount of haemoglobin is unchanged, and that the symptoms are due to the fact that the blood loses its function of transporting oxygen. Nitrobenzol, besides being used in the manufacture of high explosives, is also used to a limited extent in perfumery, soap, confectionery, and cooling processes, in making dyes, in pharmaceutical laboratories, and in shoe dyes, and it is noticeable that the people who handle it in their daily work are not those who usually suffer seriously from its poisonous action, which in most instances follows drinking it, either by accident or intentionally. Symptoms are slow in onset and vague until unconsciousness occurs. The gastro-intestinal and nervous symptoms are mainly nausea, headache, and dizziness, with a characteristic steel grey-blue colour of the skin and mucous membranes. One remarkable feature is the rapidity with which a return to normal occurs in those who recover, one patient waking up and becoming apparently normal while transfusion was being performed. This is explained by the fact that the changed haemoglobin rapidly returns to normal, so that the body cells become reoxygenated quickly. There is no specific or antidotal treatment, but the stomach contents should be evacuated as quickly as possible, and bleeding and transfusion are indicated in severe cases.

724. Tetrachlorethane Poisoning.

PARMESTER (*Journ. Indust. Hygiene*, April, 1921) discusses the prevention of tetrachlorethane poisoning during the war in connexion with its commercial importance now in the manufacture of non-inflammable films, lacquered goods, and artificial silk. A typical case generally commences with symptoms of abnormal fatigue, discontent, general nervousness, and loss of appetite, accompanied, as the poisoning progresses, by nausea, vomiting, abdominal pains, and dizziness. Jaundice, with pale stools and bile-stained urine, may develop after several days or even weeks, followed in fatal cases by confusion, stupor, delirium, coma, and death, the insidious onset, lengthy duration of acute stage, and intense jaundice being the chief clinical features. Characteristic blood conditions may precede the clinical symptoms—an important factor in prevention, as well as in diagnosis and prognosis. The blood abnormalities include a progressive increase of large

mononuclear cells, the appearance of many immature large mononuclears, a slight elevation in the white count, a progressive slight anaemia, and a slight increase in the number of platelets, a percentage of large mononuclear white cells above 12 being the first sign of a reaction to tetrachlorethane. Blood examinations in connexion with clinical observations are necessary in regulating the employment of workers, and should render possible the prevention of all but very slight cases of poisoning. By suspending cases early from work for a time, by eliminating the susceptible, and by proper methods for enclosing and ventilating the processes and protecting the workers, tetrachlorethane may be rendered an entirely feasible material with which to work commercially, and no more difficult or hazardous to use than benzol, trinitrotoluol, or lead.

725. The Therapeutical Action of Ouabain.

ZUCCOLA (*Il Policlinico*, Sez. Prat., March 28th, 1921) describes ouabain as a glucoside extracted from a plant growing in the mountains in Somaliland. The opinions of botanists are divided as to which genus it belongs to. Ouabain is indicated in certain cases of cardiac insufficiency with acute dilatation of the ventricles and tendency to bigeminal rhythm which are not affected except unfavourably by digitalis. The drug should be administered intravenously, four injections being given every four hours, the first consisting of $\frac{1}{4}$ mg. and the others of $\frac{1}{2}$ mg. Zuccola has used ouabain in twelve cases of acute cardiac insufficiency secondary to mitral or aortic lesions, cardio-sclerosis, and infectious diseases. He found that after the first injection there was a rise of blood pressure, especially of the minimal blood pressure, whereas the maximal blood pressure did not show a corresponding rise. In correspondence with the rise of blood pressure there was a fall in the pulse rate, diuresis became more abundant, and there was improvement in the general condition. While not sharing the enthusiasm of some writers who maintain that it is absolutely harmless and has no cumulative action, Zuccola considers that in some respects ouabain may be regarded as superior to strophanthus.

726. Myocardial Tuberculosis

JAFFÉ (*Zeit. f. Tuberkulose*, April, 1921) states that in human pathology tuberculosis of the heart muscle plays only a small part, though it is by no means so rare as has been hitherto supposed. In general military tuberculosis military tubercles are frequently found in the walls of the heart (Thorel). Larger cascating tuberculous nodules have often been described in the myocardium. They may be solitary or multiple, and occur with predilection on the right side of the heart, especially in the right auricle. Among 1,200 tuberculosis autopsies which Jaffé performed during the war, he found myocardial tuberculosis twice. The distinction between syphilis and tuberculosis of the myocardium is often difficult to make, as the specific organism is frequently absent in the lesions. Tuberculosis of the myocardium in the human subject is usually haematogenous, infection being conveyed by the coronary vessels. Direct transmission of neighbouring tuberculous processes—for example, in the pericardium—and lymph-borne infection may also occur. Clinical signs of myocardial tuberculosis are most likely to develop when large areas of the myocardium, especially of the conducting system, are involved. In experimental myocardial tuberculosis in the guinea-pig, produced by intraperitoneal injection of one-thousandth of a milligram of tuberculin, Jaffé found that myocardial tuberculosis was a manifestation of a severe general tuberculosis, in which there was a rapid multiplication of tubercle bacilli in the organism.

727. Pneumococcal Septicaemia.

LAFFORGUE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 3rd, 1921) agrees with Menetrier in the belief that pneumococcal septicaemia is more frequent than is generally supposed, as it can only be revealed by blood cultures. He adds, however, that the following three rules must be observed in making the examination for such cases: (1) A systematic blood culture should be made as early as possible in all cases of pyrexia whose nature remains undetermined, especially when they are accompanied by various eruptions. (2) Considerable quantities of blood should be used, 20 c.cm. being an indispensable minimum. (3) If, as is the rule in such cases, the blood culture is made on an ordinary medium, the blood should be diluted with a large quantity of the medium, a dilution of 1 in 10 being a good rule. By observing these rules he was able to detect three cases of pneumococcal septicaemia, the first case being primary in the strict sense of the word, and the other two being associated with pulmonary tuberculosis and malaria respectively.

SURGERY.

728. Incomplete Fractures of the Scapula.

MOREAU (*Journ. de radiol. et d'électrol.*, March, 1921), who records four illustrative cases, states that the interest of fractures of the scapula consists in their rarity, only 18 examples having been found by Lonsdale among 1,900 fractures of all kinds. According to various statistics their average frequency is about 1 per cent. In spite of the view held before the discovery of x rays, fractures of the body are less frequent than those of the neck of the bone. The scapula readily escapes injury owing to its mobility on the thoracic wall, its protection by muscles, and the elasticity of its flattened portion. Fractures of the scapula have been divided by Tanton into fractures of the supraspinous and infraspinous fossae, fractures of the inferior angle, fractures of the supero-internal angle, and fractures of the spine. Incomplete fractures of the upper border of the scapula have a fairly definite individuality. They cannot be mistaken for fractures of the supero-internal angle, in which the fragment is always of considerable size, and there is no abnormal mobility or crepitation, as the fragment is too deep to be felt beneath the fibres of the trapezius and infraspinatus, but on palpation a distinctly tender spot is detected above the middle part of the spine of the scapula. Functional disturbances are ill marked. The lesion to the bone may escape recognition even on x-ray examination, for the cervical border of the bone is often difficult to see on the plate, especially on superficial examination. If left to itself incomplete fracture of the upper border of the scapula may be consolidated without leaving any loss of power, but often pain persists and there is a more or less marked limitation of the movements of the shoulder, and palpation of the trapezius above the spine of the scapula is painful. If this condition persists removal of the bony fragment is indicated.

729. Direct Fractures of the Calcaneum.

MOREAU (*Paris méd.*, April 16th, 1921) states that up till now little has been known about direct fractures of the calcaneum. Although they are undoubtedly rare in peace time, they were frequent during the war, and Quénu was able to collect 30 cases in 1916. Moreau has also observed 30 cases, in 17 of which the calcaneum alone was fractured, and in 13 there was an associated fracture of neighbouring bones, such as the cuboid, astragalus, scaphoid, and metatarsals. The diagnosis of a lesion of the calcaneum does not offer any difficulty when the projectile has struck the back of the foot in the submalleolar zone corresponding anatomically to the position of the calcaneum, although it cannot be definitely stated that the astragalus and cuboid are not also injured. But there are tangential lesions which may have grazed the bone without causing definite signs of fracture. In all these cases x rays will establish the diagnosis and determine the gravity of the prognosis. The prognosis is good when the bone is only grazed, even when there is secondary formation of an osteoma, and also in "tunnelization" of the bone by a bullet when the articulations with the astragalus and cuboid are not affected. In comminuted fractures the prognosis depends on the degree and extent of the bony lesions. In almost all Moreau's cases the foot could be preserved, and in only one case was it necessary to perform a supramalleolar amputation, and in another astragalotomy. In most of the cases scraping, sequestrotomy, and partial resections were sufficient.

730. Hallux Valgus, Rigidus, and Malleus.

JANSEN (*Journ. Orthopaedic Surg.*, March, 1921) points out that hallux valgus, rigidus, and malleus may occur separately, but are usually associated. Disturbance of motion, valgus, and joint wear, most prominent in hallux rigidus, are the main principles underlying the deformities. Hallux rigidus is due to extra strain upon the first metatarsophalangeal joint, and may occur in people with everted foot and muscle weakness from outgrowth of strength. Flattening of the metatarsal head, shortening of the bone, lipping and thinness of the joint cartilage are noticeable; the lipping causes pain in walking, gradually leading to permanent involuntary contracture of the flexor brevis muscle and producing hallux malleus. This latter, by causing the abductor hallucis to slide downwards, thus losing its abduction power, may produce hallux malleo-valgus when the power of the adductors prevails. Hallux valgus is generally produced by the wearing of narrow-pointed shoes with high heels causing luxation of the extensor proprius and flexor longus hallucis. These conditions may

be prevented by the use of well-fitting shoes with the inner border raised, attention being paid to muscle balance and joint wear. Transplantation of the abductor hallucis is useful, and with this may be combined shortening of the first metatarsal bone by Ludloff's method or by the removal of part of the metatarsal neck. In the discussion which followed upon Professor Jansen's paper complete removal of the head of the bone was considered to be the best line of treatment for the condition.

731. Non-union following Fracture.

ROBERTSON (*Canadian Med. Assoc. Journ.*, May, 1921) discusses non-union following fracture. Since fibrous union never becomes bony, interference is necessary in weight-bearing bones, either by a graft or a mortise. A bone transplant has no inherent value as a nidus from which bone will develop, but is merely a scaffold through which bone will grow and absorb what it replaces. In bone-grafting it is essential to have a wide expanse of raw viable bone intimately opposed to a wide expanse of transplant, so that revascularization and regeneration of the graft may rapidly occur. In mortising, union follows early when living fragment is opposed to living fragment. Technique varies with the bone to be treated. In the femur and humerus, with little loss of bone tissue, mortising produces a stronger union, and no attempt should be made to fill a defect by applying a transplant. Mortising is performed by making one fragment a spearhead and the other a cleft so shaped that when fitted together raw bone is intimately associated with raw bone held immobile with plate and screws of bone. In the radius, ulna, or tibia long defects may be bridged by transplants, since in each case there is a companion bone to assist in weight-bearing. With an accurately cut, firmly fitting, diamond-shaped graft, union is certain to occur. The limb is splinted in plaster-of-Paris for three months or longer. In military cases infection frequently occurs but does not preclude union; such infection usually gives rise to symptoms within thirty hours, though occasionally its development may not occur till later.

732. Pyelography and Uretrography.

GOLDSTEIN (*Amer. Journ. of Surgery*, April, 1921) considers uretrography and pyelography as absolutely essential for diagnosis in many urological conditions and as a great aid in differential diagnosis, being a harmless procedure not contraindicated in any abdominal cases presenting a suspicion of urinary tract lesion. No purgative should be given for twenty-four hours prior to the examination, so that the distribution of gas in the bowel may be undisturbed and so cause no difficulty in interpreting suspicious shadows. Plain radiograms are made first for comparison with the uretrogram or pyelogram. The next day cystoscopy and pyelography or uretrography are performed with a radiographic catheter, a Garceau catheter being used if leakage is present. The catheter is inserted slowly into the ureter on the suspected side for about eight or ten inches, the required distance being measured previously on the catheter, the aim being to allow its tip just to enter the kidney pelvis without lodging against any kidney tissue. If in doubt about measurements it is inserted until the natural obstruction is encountered and then withdrawn about an inch. With a graduated syringe sterile water is very slowly injected through the catheter until a sense of fullness or commencing pain is complained of in the renal region, this giving the capacity of the kidney. The opaque solution is next injected, 2 c.cm. less than the total amount of water being used, so as to avoid distension, and before removal of the catheter this solution is drained off and the kidney pelvis washed out with water. Both kidneys are never injected at one sitting.

733. Tourniquet for Intravenous Injections.

BARNES (*Med. Record*, April 23rd, 1921) describes an ideal tourniquet for use in intravenous injections which can be quickly and accurately adjusted and loosened. It consists of a half-inch wide woven strap with a buckle that catches at any point. After passing this round the arm and through the ends of a block of wood, over the upper surface of which it passes, it is fastened just below the block, which has been placed on the upper surface of the arm at the insertion of the deltoid. A wedge-shaped piece of wood is pushed between the top of the block and the strap until the desired degree of constriction is obtained. The block is sufficiently long to project beyond the convex surface of the arm, so that the skin will not be pinched against its ends when the strap is tightened, and the tourniquet is loosened by removing the wedge, which

can be easily done if necessary by the patient, thereby increasing the ease with which an injection can be given when there is no assistant.

734. Morning Pain in Renal and Ureteral Calculus.

BÄRSONY (*Wien. Med. Woch.*, April 14th, 1921) maintains that the occurrence of pain in the morning in the renal region, sometimes radiating to the bladder and testes, should always suggest renal or ureteral stone. In some patients the pain occurs exclusively during the morning, and in others at other times as well. It seems as though small stones in the renal pelvis and those that pass into the ureter more frequently cause pain in the morning than larger stones. The cause of the pain occurring early in the morning is obscure. Bärsony attributes considerable importance to the recognition of this pain, as it will prevent renal calculus being mistaken for intestinal obstruction or appendicitis.

OBSTETRICS AND GYNAECOLOGY.

735. Etiology of Tubal Gestation.

GRISER (*Zentralbl. f. Gynäk.*, April 9th, 1921) has found that of recent years an increasing percentage of Fallopian tubes which have been the seat of ectopic gestation show, when submitted to microscopical examination, an absence of inflammatory appearances in the mucosa. Sobotta and others have shown that ciliated epithelium is absent from the Fallopian tubes of many mammals, and it has been suggested that in such animals the tran it of the ovum is due, not to ciliary action, but to muscular peristalsis which is under nervous control. Griser believes that in the human Fallopian tube both ciliary and peristaltic factors play a part, and notes that in the specimens removed at recent operations for ruptured ectopic pregnancies which showed no evidence of chronic inflammatory change, there was distinct hypoplasia of the tubal (and sometimes the uterine) musculature. This hypoplasia he attributes to chronic under-nourishment of the patients during the war.

736. Torsion of the Virgin Fallopian Tube.

HEIL (*Zentralbl. f. Gynäk.*, April 9th, 1921) records a case of torsion of the Fallopian tube in a virgin. An unmarried woman, aged 27, two days after a slight abdominal trauma, suddenly fainted and began to have vaginal bleeding. Ruptured ectopic pregnancy was suspected. Examination under general anaesthesia showed the uterus to be of normal size; to the right was a movable tumour the size of the fist, while in the posterior and left fornices was a resistant and extremely tender swelling of similar dimensions but not quite so well defined. Exploratory puncture of the first-named tumour gave a thick fluid resembling the contents of a dermoid cyst; aspiration from the postero-lateral swelling gave thin fluid blood. The patient denied that pregnancy was possible. At laparotomy, performed three days later, the tumour on the right, which was shelled out and extirpated, was found to be an ovarian dermoid cyst, showing a commencing torsion; on the left the tube and ovary were found to be the seat of torsion of two and a half turns, and to be enlarged and congested. The tumour which had been palpable in the posterior and left fornices was an effusion of blood which had originated from the rupture of a follicular haematoma in the left ovary. Torsion of the Fallopian tube in a virgin is an event of extreme rarity; according to some authors, twisting of the tube occurs only in connexion with coexisting ovarian tumours, or with sacrosalpinx.

737. Indications for Symphysiotomy.

SCHWARTZ (*Zentralbl. f. Gynäk.*, April 16th, 1921) describes his last 28 cases of symphysiotomy, which he has performed on 113 occasions in all, with results which lead him to draw favourable conclusions as to the value of the operation. Of the 28 cases, 15 were primiparae and 13 multiparae. In the former group birth after symphysiotomy was spontaneous in 4 instances; 1 vesico-vaginal fistula, 4 small (uncomplicated) haematomata of the labium majus, 2 cases of slight prolapse (after episiotomy), and 4 instances of slight haematuria were the post-operative complications encountered. Among the 13 multiparae operative delivery was induced in all instances, and 2 patients suffered from small haematomata; 2 had previously undergone Caesarean section and 3 symphysiotomy. There was no foetal mortality. During the four days following operation the patients lie between sandbags; they are allowed to stand on the eighth or ninth

day. Reviewing the criticisms which have been directed against symphysiotomy, the author points out that severe bladder injuries occurred in 5 only of his 113 cases and slight transitory haematuria in 22; it is to be remembered that extraperitoneal Caesarean operations are by no means free from similar complications. Of the 113 cases, the low mortality and the fact that Caesarean operations carry with them the danger of hernia formation or of subsequent rupture of the uterus. Schwartz proceeds to a comparison of the drawbacks attaching to symphysiotomy and Caesarean section respectively. The maternal mortality of the latter operation has ranged in various hands from 2 to 6.3 per cent. (symphysiotomy 2.6 per cent.). The average foetal mortality reported after Caesarean section is lower than Schwartz's figure of 7 per cent. after symphysiotomy. Against this must be set, it is urged, the fact that symphysiotomy diminishes, while Caesarean section increases, the chance of foetal death in subsequent pregnancies. The author is accustomed to employ this method not only in head, but transverse and breech presentations. It is a special advantage of symphysiotomy under local anaesthesia that it may be performed in young primiparae; if after the operation it is evident that spontaneous birth is not to be expected, recourse may still be had to Caesarean section, or occasionally (in carefully selected cases) to delivery by forceps. Existing infection, a contra-indication for Caesarean section, is said not to diminish the applicability of symphysiotomy. The author summarizes the indications for the operation as follows: (1) In contracted pelvis with a true conjugate of 7.5 cm. and upwards, when, in spite of good uterine contractions and the use of Walcher's position, the head does not engage. (2) Moderate stillbirth; here metrorrhysis may be useful at the same time. (3) Moderate degrees of pelvic contraction, when there is transverse or breech presentation, or when podalic version is to be performed. (4) Brow or face presentations in pelves of normal dimensions, when forceps are to be applied.

Treatment of Septic Abortion.

738. *PECK (Amer. Journ. of Obstet. and Gynec., April, 1921),* who ranges himself with the advocates of conservative treatment for cases of abortion complicated by sepsis, employs Fowler's position and orders vaginal douching in exceptional cases only. Haemorrhage is regarded as the only symptom which may demand prompt and thorough emptying of the uterus. For the treatment of haemorrhage, vaginal packing of iodoform gauze (2 per cent.) is employed when dilatation of the cervix has not taken place, and cervico-vaginal packing, when, in spite of much dilatation has occurred, instrumental removal of the products of conception is regarded as too hazardous. After spontaneous expulsion, these products, if not already removed by the finger, aided, if necessary, by forceps. In haemorrhage during or after the third month, with incomplete cervical dilatation, the use of a colpeurynter is considered preferable to rapid and forcible dilatation or to vaginal hysterotomy.

PATHOLOGY.

739. *The Regeneration of Peripheral Nerves.* A SUMMARY is given by LHERMITTE (*Ann. de Méd., April 1921*) of the recent changes of view that have occurred in connexion with the regeneration of peripheral nerves. From the work of Dustin, it appears probable that the direction which is followed by the budding axis cylinders of the central end of the nerve is determined largely by the active proliferation of the cells of the sheath of Schwann around the peripheral end; from this end there is formed a syncretism of growing cells, into the meshes of which the regenerated axis cylinders find their way. The fundamental tendency existing for the two ends of a divided nerve trunk to unite again is explained by two theories, in favour of each of which experimental evidence is adduced: (1) The degeneration of the severed nerve produces an alteration in the electrical potential existing at the surface of the nerve trunk; from the normal positive it becomes negative, and persists negative during the whole period of degeneration. This difference in potential acts not only as an excitant of cellular regeneration, but determines the direction of growth of the axons; to this current

existing between the cerebral and peripheral ends of the divided nerve is given the term "current of regeneration." (2) Marinesco has shown that in regenerating nerves certain ferments appear, one of an organic nature having its origin in the granules of the protoplasm of the sheath of Schwann, and the other of an inorganic (ferrous) nature which plays the part of a catalyzer of peroxidase. It is probable that these ferments are closely related to the growth of the regenerating nerve. From the surgical point of view the best means of ensuring the union of the two ends of a divided nerve is neither by the use of a piece of vein, nor of living nerve tissue, nor even by direct suture of the two extremities, but by the interposition of a fragment of nerve killed and fixed in alcohol or formal.

740. Hepatitis and Nephritis Secondary to Round Ulcer of the Stomach.

LE NOIR, RICHET, and JACQUELIN (Ann. de méd., April, 1921) find that hepatic and renal insufficiency are frequently present in patients suffering from round ulcer of the stomach. In investigating the functions of the kidney, the blood urea, the non-protein nitrogen of the blood, and Ambard's constant were determined, while in the case of the liver, alimentary glycosuria, and the presence of urobilin, blood, digestive haemoclasis, and the presence of tissue uria were the methods employed. The insufficiency of these organs is correlated not so much with the age of the ulcer as with its extension and the amount of tissue destruction it gives rise to. Once cicatrization of the ulcer occurs, the hepatic and renal insufficiency seems to disappear. On these lines they explain the origin of haematemesis, holding that in some cases this is due largely to the decreased coagulability of the blood. Similarly, certain cases of intractable vomiting are considered to be due to a hepato-nephritis—a theory supported by the fact that the autopsy of fatal cases of this nature revealed the presence of cirrhosis and fatty degeneration of the liver, together with chronic nephritis. Operative shock is particularly severe in many cases, and post-mortem observations reveal the presence of marked hepatic lesions following gastro-enterostomy; this shock they attribute to a definite post-operative hepato-nephritis. From a therapeutic point of view they advise caution in the use of opium and of chloroform water in making up prescriptions for the relief of pain, while for the production of anaesthesia for operation they prefer nitrous oxide or local anaesthetics to chloroform. The presence of the post-operative should be carefully tested for during the post-operative period, to afford evidence of hepatic insufficiency. Acidosis, which is very liable to appear, should be combated by the administration of carbohydrates and of alkalis in large doses.

741. Pathology of Pregnancy Toxaemias and Nephritis.

FROM an examination of 12 cases of toxæmia of pregnancy, 20 cases of nephritis in pregnancy, and numerous controls, *MACKENZIE WALLIS (Journ. of Obstet. and Gynaecol. of the British Empire, 1921, i)* finds that in the toxæmias of pregnancy the blood content is normal with respect to urea, sugar and other constituents; the absence of alteration in the sugar content is regarded as evidence against the view that pregnancy toxæmias are associated with endocrine gland disturbances. Analysis of the urine shows that the ratio of albumin to globulin is about 6 to 1 in nephritis as compared with about 2 to 1 in the toxic women the diastase content of the urine is remarkably constant and does not differ from that found in the non-pregnant or in males. In true toxic vomiting of pregnancy and in eclampsia, on the other hand, the diastase content of the urine is much increased; it may remain abnormally high after other signs and symptoms of toxæmia have disappeared and may by a sudden increase in the advent of toxæmic manifestations. In normal pregnancy, unlike pancreatic disease, there is no marked increase in the diastase in the blood. In nephritis in pregnancy, the diastase content of the blood is increased while that of the urine becomes diminished with the renal permeability usually very considerably. Estimation of urea in the blood indicates whether there is urea retention, and therefore diminished renal function, and may thus form a basis for prognosis in nephritis in pregnancy; the urea content of the blood does not, however, give any clue as to the imminence of uraemia. In assessing the degree of renal damage which is present and in forming a prognosis, all the tests mentioned should be given to the result—
